INTERNATIONAL CONFERENCE ON TRAFFIC AND TRANSPORT ENGINEERING

ICTTE

November 24-25, 2016
Belgrade, Serbia

- ICTTE BELGRADE 2016 -
PROCEEDINGS OF THE THIRD INTERNATIONAL CONFERENCE ON TRAFFIC AND TRANSPORT ENGINEERING

ICTTE Belgrade 2016 has been jointly organized by the City Net Scientific Research Center Ltd. Belgrade and University of Belgrade, Faculty of Transport and Traffic Engineering. ICTTE Belgrade 2016 has been co-hosted by the AIIT (Associazione Italiana per l'Ingegneria del Traffico e dei Trasporti) Research Center, Rome, Italy and UITP (International Association of Public Transport) and has been organized under the auspices of the Italian Society of Transportation Infrastructures (SIIV – Società Italiana di Infrastrutture Viarie). The conference is held in Belgrade, Serbia, from 24th to 25th November 2016.

The conference covers a wide range of topics related to traffic and transport engineering, with the aim of representing the importance of all modes of traffic and transport, especially the importance of improving these industries, and their compliance to one of the most significant principles nowadays, sustainable development. ICTTE Belgrade 2016 gathers researchers, scientists and engineers whose fields of interest are traffic and transport engineering, and should provide them a good platform for discussion, interactions and exchange of information and ideas. ICTTE Proceedings have been indexed within Thomson Reuters's CPCI – Conference Proceedings Citation Index accessed via Web of Science.

PREFACE

Each year billions of Euros are spent globally in order to develop, manufacture, operate and maintain transportation systems and vehicles. However, each of these processes begins with scientific research which contributes to modern life principles.

Paralleling the spurt of work on new transportation principles, there has been renewed attention to their influences on mobility, economy, safety, security, urban planning, pricing, environmental protection, etc.

Keeping in mind our main scientific gain - to learn, discover and spread our knowledge to the new generations, I would like to believe that International Conference on Traffic and Transport Engineering - ICTTE2016 has a new role not just to connect among ourselves or our institutions, but to encourage each of us to share the great knowledge and years of dedicated work.

Moreover, I would be sincerely proud if this journey via different modes of transportation could be replaced by communication and information flows through our scientific network.

This proceedings is a result of the work of over 200 researchers from more than 30 countries worldwide and I wish you pleasant reading of selected topics.

INVITED PAPER

WEB GRAPH ANALYSIS OF THE AIR TRAFFIC SAFETY COMMUNITY

Miloš A. Kovačević[1]
[1] *University of Belgrade, Faculty of Civil Engineering, Bulevar kralja Aleksandra 73, Belgrade, Serbia*

Abstract: The structure and properties of the web graph originating from the air traffic safety community could reveal many interesting relationships which exist between key organizations in the field. Therefore, an attempt is made to collect a representative sample of relevant web pages from different sources, by utilizing an intelligent software agent capable of recognizing the concept of a typical air traffic safety page. Starting from a seed set of thirty relevant pages, the agent collected nearly 200,000 on-topic pages and recorded the links between them. The analysis of the compiled graph detected the most relevant pages and sites, common linking patterns and popular keywords used for titles and links texts.

Keywords: web graph, focused crawling, air traffic safety.

1. Introduction

World Wide Web can be represented as a graph G in which vertices correspond to web pages and edges to hyperlinks defined with related URLs. G is a directional graph, since a hyperlink can be followed only in one direction. Investigating the properties of G could lead to many interesting applications, but probably the most important application is related to the Page Rank algorithm (Brin and Page 1998.). Page Rank is used by Google to calculate the relevance of pages retrieved as answers to a user query. In (Flake et al. 2002.), Web communities are defined as strongly interconnected pages speaking about the same topic. Authors discuss the possibility to extract the communities merely using the connectivity information stored in the graph. Obviously, linking patterns can reveal interesting relations between different organizations that are present on the Web, and can help in finding the most appropriate information sources. In this paper, the author tries to analyze the Air Traffic Safety (ATS) community from its presence on the Web. The analysis is performed by using sophisticated machine learning techniques (Mitchell 1997.) which enable the recognition of an ATS page in G, and a software system capable to record the existing links between such pages.

2. Topical web graph and focused crawling

Topical web graph G_T is a subgraph of G in which all nodes represent pages related to a certain topic T. In this paper, T represents the air traffic safety (ATS) thematic which includes aircraft operational safety, rescue and emergency services systems, traffic control, legal issues, R & D and others. The pages from T are distributed among different sources such as international and governmental bodies, professional associations, companies, educational institutions and blogs. In order to analyze G_T, one first needs to visit as many as possible pages from T, and to record the links between them. The construction of G_T is a very complex task for manual execution, since experts are not able to examine efficiently large portions of the everyday changing community. Therefore, an automatic approach is needed to systematically record G_T at any given point in time. In this research, a system for acquiring relevant data from the Web, and building the related G_T, is proposed and evaluated on the ATS pages. The system is based on a topic-specific automated crawler (Kovačević and Davidson 2008), which is capable of discovering on-topic pages, using the machine learning techniques.

A crawler is a software component designed to visit web pages by using the HTTP(S) protocol, and to save them in a database for further analyses. It performs the task by starting from a seed set of initial addresses and, following links that connect neighboring pages, collects as many pages as possible. A focused crawler fetches only the pages that belong to a specified topic (Chakrabarti et al. 1999) by exploiting the fact that the Web is a "social network", and that pages mostly reference similar pages (Davison 2000). Therefore, when a visited page is judged to be relevant, its links are followed too, otherwise not - see Figure 1. Focused crawlers are used in a variety of applications, such as vertical search engines (McCallum et al. 2000), competitive intelligence (Chen et al. 2002), and digital libraries (Pant et al. 2004; Qin et al. 2004). There are two main issues related to the design of a successful focused crawler: how to recognize whether a page is on topic or not, and how to reorder links extracted from on-topic pages in such a way that the crawler visits the more promising pages before potentially less relevant ones (Pant and Srinivasan 2005).

[1] Corresponding author: milos@grf.bg.ac.rs

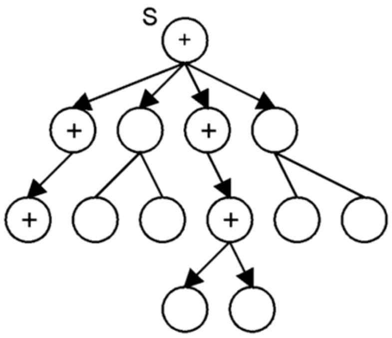

Fig. 1.
Focused crawler: starting from a seed page S, crawler follows only promising links while collecting on-topic pages (+). Links without arrows are not followed.

In the proposed system, a modification of Positive Examples Based Learning (PEBL) classifier (Yu et al. 2004) is used to determine if a visited page is on-topic, as it is described in the next section. Given a page *p*, PEBL outputs the probability of *p* belonging to the topic T. Despite the fact that relevant pages often point to other relevant pages, there exist situations in which one can reach the on-topic page by following a link from an off-topic page (i.e. a page from the air traffic community but not related to the safety issues, or a news agency page). Therefore, an approach is applied to take into account promising links from off-topic pages. Let *l* be a link contained in a page *p*. The proposed classifier outputs two probabilities: the probability of the whole *p* belonging to T, and the probability of the *l*'s anchor text and surrounding textual neighborhood being from T. Final decision for a link *l* to be followed is made after calculating the weighted sum of these two probabilities. Topical graph G_T is constructed by recording the paths traversed in the crawling session.
Focused crawlers periodically revisit already crawled places in order to detect new pages and sites in a community. Since the portion of the crawled Web is very small, the freshness of the acquired information is much better when compared to general purpose search engines like Google (Pant and Srinivasan 2005).

3. Detecting on-topic pages

Let + and – be the class labels assigned to all pages on the Web, such that pages from the topic T are labeled as + and all others as –. Suppose that there exists a function *f* which maps pages into the classes: $f(p) \rightarrow \{+, -\}$. Machine learning approach tries to find the representation of *f* from a small set of labeled examples, consisting of pages from both classes. Function *f* is called a classifier and the set of examples constitutes a training set. In order to learn the classifier one needs a suitable representation of each Web page. Commonly, the example pages are parsed in order to build a list of all different, extracted words. Classification vocabulary V is constructed from this list after the removal of non-informative words such as articles or numbers. Now, all the pages from the Web can be represented as vectors of word frequencies with respect to the vocabulary V (Salton 1989) - see Figure. 2a.

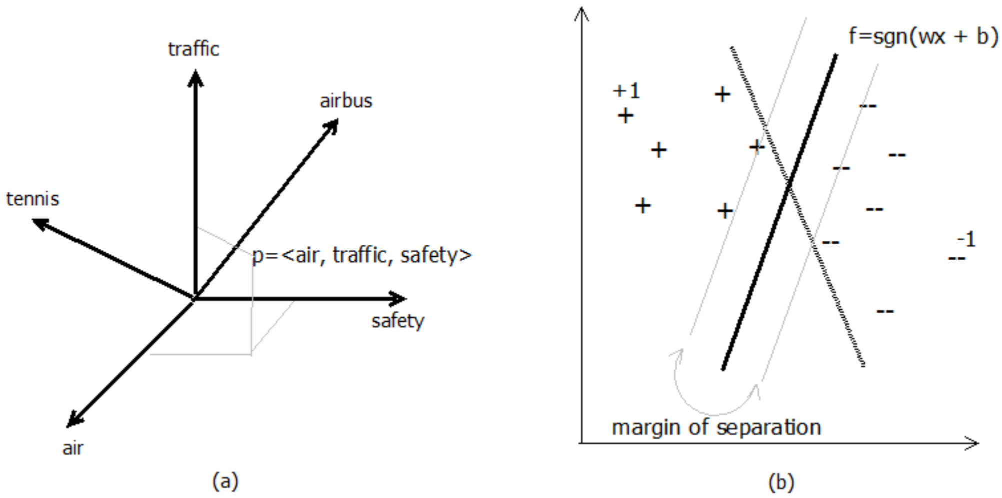

Fig. 2.
(a) Bag-of-words model: pages are points in the n-dimensional space of words, with normalised word frequencies as coordinates. (b) SVM: best separating hyperplane maximizes the margin of separation. The classification function assigns a label for an unseen instance **x** *according to its position with respect to the hyperplane (+1 above, or -1 under).*

A popular text classifier that is capable of learning the function *f* from the examples represented as vectors in the space of words, is called Support Vector Machines (SVM) (Vapnik 1995.). The essence of the basic SVM learning algorithm is described in Figure 2b. SVM tries to find a hyperplane which best separates the members of two different classes. The best separation is reached when the nearest instances from opposite classes are maximally distant (maximal margin of separation). There are two separating hyperplanes showed in Figure 2b. The hyperplane depicted with the gray, dotted line is not the appropriate one, since it lays in the middle of the very narrow margin. The best separating hyperplane $\mathbf{wx} + b = 0$ is situated in the middle of the maximal margin. Parameters **w** and *b* can be found in the learning process, which is formulated as an optimization problem on the training set. SVM is able to establish only a linear separation between classes, but is nevertheless suitable for web page classification due to high dimensional space of words (tens of thousands of words), in which classes become more linearly separable.

Original SVM is not suitable for building a focused crawler since it requires the examples from both positive (topic T) and negative class. While one can easily acquire certain number of pages from T, it is very difficult to model the negative class appropriately (everything on the Web which does not belong to T). Therefore, a Positive Examples Based Learning approach is applied in the proposed crawler, which utilizes the SVM algorithm, but instead of learning from positives and negatives, it constructs the classifier trained on a small set of positive (P) and a large set of unlabeled (U) examples. Unlabeled examples can be easily downloaded from the Web without the need to explicitly assign pages to certain classes. In this research, about 10.000 pages in English were downloaded from 15 top level categories of the Open Directory Project (http://www.dmoz.org).

PEBL is an iterative algorithm which tries in each iteration to increase the number of discovered negative examples from the unlabeled set U. In the first iteration, a list of strong positive words is formed. A word is a strong positive feature if its document frequency (number of documents in which it occurs) in P is higher than the corresponding document frequency in U. Pages from U which do not contain none of the strong positive features are considered to be strong negative examples. They are added to the initially empty set N^1 which is used, together with P, to train a classical two class SVM linear classifier. Such SVM is further applied on the $U \setminus N^1$ to extract additional negative examples. In the *k*-th iteration, N^k is constructed by adding newly found negatives to N^{k-1}, and the next SVM is trained on N^k and P. Algorithm terminates in the *n*-th iteration when there are no more negatives extracted from the remaining unlabeled pages. The decision classifier becomes the final SVM, trained on sets P and N^n.

The output of the classifier can be transformed into a class probability, by assuming that points located far away from the final SVM hyperplane have higher class probabilities than the closer ones. PEBL is sensitive to the number of positive examples, since more positives enable better estimates for initial, strong positive words.

4. Constructing ATS web graph

The proposed system for web pages acquisition and the associated topical graph construction is implemented as the author's private startup project (http://semanticjuice.com). In order to analyze the web graph of the ATS community, a classifier based on PEBL is trained on 30 initial examples, and the focused crawler is instructed to start from the seed set of 33 pages (Table 1). The examples are obtained from an independent expert in the field.

Table 1
Parameters of the ATS crawl

Examples	Seeds

https://ec.europa.eu/transport/modes/air/safety/safety-rules_en https://www.cranfield.ac.uk/courses/taught/safety-and-accident-investigation-air-transport https://www.eau.ac.ae/english/courses/postgraduate-studies/msc-aviation-safety.aspx http://www.aopa.org/training-and-safety/air-safety-institute http://www.aopa.org/training-and-safety/air-safety-institute/safety-spotlights	

After 24 hours of work, the system visited 1,625,453 pages and recognized 171,124 pages to be on-topic. The resulting ATS graph contained 171,124 vertices and 14,782,887 edges (links). There were 1,821,423 promising URLs known to the system, but the computing resources did not allow for further crawling (other commercial crawls were in progress).

5. Estimating classifier precision

After the crawling has been finished, the analysis is conducted to estimate the accuracy of the topical classifier. Since it is not convenient to verify whether each page *p* labeled as on-topic is correctly classified, a query is formulated to find if *p* contains words from two groups of keywords (*airplane*, *aircraft*, *aviation*, *helicopter*, *drone*, *pilot*, *airport*), and (*safe*, *safety*). The *p* is considered to be correctly classified if it contains at least one keyword from both groups. Table 2 shows the percentage of correctly classified on-topic pages during the progress of the crawl.

Table 2
Percentage of the correctly classified pages, after n collected on-topic pages

1,000	10,000	50,000	100,000	171,124
77 %	63 %	63 %	57 %	53 %

Slow decrease in classifier precision during the progress of the crawl can be partially explained as an effect of going further and further from the example pages, and slowly leaving the ATS community portion of the Web. As a final note on the estimated precision, the introduced verification rule is highly approximate, but appeared to be quite satisfactory when a random sample of 100 links is verified after the termination of the process (55 % correctly classified in the sample). The achieved performance of the PEBL classifier should be better if one increases the number of initial examples (Kovačević and Davidson 2008).

6. Community analysis

Due to limited space in the paper, a short, incomplete description of the ATS community graph is presented. Detailed properties of the graph can be found at https://www.semanticjuice.com/aviation-safety/. Please note that the reported analysis follows from the collected sample which is highly dependent to the initial set of examples.
Table 3, column two, lists the most important domains in the ATS community, according to the ranking function which combines relevance and popularity scores. Domain relevance is calculated as the average probability of an on-topic page being on-topic (the probabilistic output of the PEBL classifier). Domain popularity is proportional to the number of other relevant domains which link to the domain under consideration. Domains which are linked the most from other relevant domains are listed in the next column of Table 3. In addition, the graph memorizes who links to, for example, domain *cad.gov.rs*, revealing that Civil Aviation Directorate of Republic of Serbia should work more to increase the public awareness of its existence (last column). Interestingly, for the same query used to test the classifier precision, Google outputs the *aviation-safety.com* as the first result too.

Table 3
Domains stats (first fifteen from the highest to the lowest rank)

Importance	Most links from other relevant domains	Most links to *cad.gov.rs*

When performing the crawl, the proposed system recorded not just the links between pages, but the page titles and texts associated with the links. This is very important information if one wants to analyze how the owner of a site perceives the other site (organization). As an example, Table 5 lists fifteen links from *flightmemory.com* to *aviation-safety.net* containing the word *airbus* in a link text.

Table 5

7. Conclusion

In this paper, an analysis of the web presence of key air traffic safety organizations is presented. After collecting nearly 200,000 on-topic pages, starting from a seed set of 30 examples, the intelligent focused crawler constructed a web graph of the ATS community. The precision of the machine learning constructed classifier appeared to be nearly 60%, which can be further improved by adding more initial examples. The processing of the constructed topical graph revealed the most important sites and pages in the community. Topical graph can be used to detect linking patterns between organizations. The complete analyses can be found on http://semanticjuice.com.

SESSION 1: AIR TRAFFIC AND TRANSPORT RESEARCH AND INNOVATION

CONCEPTUAL ADVANCEMENTS FOR AN ADAPTIVE AUGMENTED VISION BASED ASSISTANCE SYSTEM FOR AIR TRAFFIC CONTROL TOWERS

Hejar Gürlük[1], Philipp B. Sinapius[2]
[1,2] Institute of Flight Guidance, Department of Controller Assistance, German Aerospace Center (DLR), Braunschweig, Germany

Abstract: This paper describes the enhancements of a novel concept of operations for future assistance systems for tower air traffic controllers developed by the Institute of Flight Guidance at the German Aerospace Centre (DLR). The concept envisions a wearable head up display that projects operational data into the air traffic controllers' outside view. Based on a multi-dimensional adaptive automation model the system monitors both the operational environment and the air traffic controllers' behaviour. The assistance system adapts the information presentation on the head up display accordingly following the premise to display the right (amount of) information at the right time. This paper presents further advancements of this concept. These are largely based on field observations and workshops conducted with controllers at two German air traffic control towers of mid-sized airports. The main aim of the workshops was to assess the importance of certain bits of information in relation to the traffic situation and environmental conditions. The key enhancements introduced in this paper comprise an information model determining the most relevant information for dynamic and static head up information presentation as well as an innovative adaptive radar label concept tailored to the current operational conditions in the control tower. Also several conceptual designs that were developed together with the controllers will be presented in this paper. As the results are based on expert opinions, the concept is close to the operational reality and promises to reduce the workload for air traffic controllers required for the search of information during nominal tower operations. The concept with its advancements serves as a base for on-going prototype implementations and simulation studies planned with air traffic controllers in the near future.

Keywords: air traffic control, tower, augmented vision, adaptive, assistance system.

1. Introduction

Air traffic controllers (ATCOs) ensure a safe, orderly and economic air traffic flow. ATCOs continuously have to evaluate new flight information or related information, and closely coordinate and communicate their efforts with other air traffic control units and stakeholders such as ground handling services. Tower ATCOs are in general responsible for the aerodrome traffic on a controlled aerodrome. Tower air traffic control operations can be referred to Tower Control (TC) and Ground Control (GC). In general, TC encompasses the handling of arriving and departing airborne traffic within the aerodrome control zone as well as traffic on runways. GC predominantly directs aircraft to and from the runway via taxiways and is responsible for the control of other aircraft and vehicular movement on the airport movement area. Both can require the dissemination of relevant information such as traffic, weather, equipment status, flight plans, revisions etc. (Ruffner, 2008).
Tower air traffic control requires a continuous monitoring and processing of numerous information sources. In view of today's tower controller working positions (CWP), they are typically characterized by a high number of distributed information and support systems referred to as "head down" displays. Often each of these widely distributed head down displays provides its own human machine interface (HMI) components and interaction devices. Additionally, ATCOs have to mentally merge the different information sources, including the outside view, in order to obtain adequate situational awareness. Altogether can potentially lead to higher workload in terms of prolonged times for information acquisition and analysis (Gürlük, 2016).
Apart from the head-down displays the main information source for tower ATCOs still remains the outside view referred to as "head up". The outside view is essential for tower operations in order to obtain the current aircraft position and maintain adequate situational awareness. However, a continuous transition from head up to head down which is an integral part of the controllers work in a tower environment can be quite critical for tower operations if head down times are prolonged and thus possibly lead to hazardous incidents as for instance runway incursions (Hilburn, 2004).

2. Theoretical Background and Motivation

One possible option to mitigate the above mentioned "head up vs. head down" problem could be an augmented vision solution projecting critical flight data onto the natural outside view of the tower ATCO. The integration of augmented data within the tower environment has become a research interest within the last years (Reisman, 2006; Bergner and Schmand, 2013; Hofmann et al., 2012). These systems however showed particularly deficits in regard of display ergonomics and user- and context sensitive information presentation. Typically information was displayed for all aircraft in the view of the head up display regardless of the ATCO's specific information needs. This causes information to overlap and hence to over-clutter the ATCO's primary field of view when there are several aircraft movements. Research showed that it would be also of particular interest for which aircraft in the ATCO's field of view which information has to be displayed that is relevant in the current situation (Schmand and Bergner, 2013). Research analysis also revealed,

[1] Corresponding author: hejar.guerluek@dlr.de

that no work has been published on state-of-the-art wearable augmented vision display technologies that allow both tailored information presentation and multi-user operations for tower air traffic controllers. Also the manipulation of augmented data has not been investigated yet.

In response to the described issues a novel concept for the display of augmented tower air traffic control data in combination with a multidimensional adaptation model was proposed by Gürlük (2016). Hereby, the information presentation is tailored to the ATCO's informational needs in dependence of the current user behaviour, task, environmental conditions and operational constraints. The concept which serves as the basis for the envisioned assistance system encompasses a multi-dimensional adaptive automation model that combines operator-based and context-based adaptation triggers. First, the system collects data via sensors and information systems in order to assess the operational context and operator behaviour (see Figure 1, left). The selection of the operator-based adaptation triggers such as speech recognition, eye-tracking and user input is based on the premise to consider sensors that are presumably operationally feasible within the airport tower environment. This requires unobtrusive sensors which are not attached to the body or even worse impair the mobility and comfort of the operator. For the context-based adaptation triggers the following data sources were selected: surveillance data from aerodrome surveillance and ground radar, flight plan data, environmental data (weather, wind, visibility conditions, etc.), and planning information derived from air traffic control (ATC) planning systems.

The assessment of the operational context and ATCO behaviour can then be used, in isolation or combination, to trigger the decision of which adaptations to select. The envisioned assistance system currently is limited to adaptations of the information content and interaction mode. Adaptation to information content is straightforward: the dynamic decluttering adaptations based on operator and/or context-based adaption rules are used to help the ATCO focus on only the most relevant information for the task at hand. When modifying the content, it is crucial to provide the ATCO with the information needed to successfully accomplish the work. The other adaptation, modification of interaction, comprises adaptations to the interaction style and interface features, e.g. visual or auditive information augmentation to direct the attention. As the ATCO represents the final decision authority, the ATCO can intervene and adapt the information according to his needs via user input whenever the display content needs to be updated, is not available, incomplete or not desired. This is why the proposed concept incorporates also the manipulation of augmented data (see figure 1, bottom right) and synchronization with head-down devices such as electronic flight strips (Gürlük, 2016). If the ATCO for example inputs given clearances into the electronic flight strips system, the clearance appears within the augmented labels as well. Particularly in early design phases the synchronization with head-down devices such as electronic flight strips must be provided to enable a smooth transition from status-quo systems towards new HMI concepts on one hand and also to help the ATCO to maintain adequate situational awareness in a user-accepted system (Ohneiser, 2016) on the other hand. The concept foresees also browsing through augmented data by means of interaction devices in order to select a specific target (see figure 1, bottom right). Finally the adaptive changes are then executed by the adaptive system if accepted by the ATCO or by user input via the human-machine interface. The control loop is closed by continuous monitoring of the trigger values described above by the automation for a continuous adaptation.

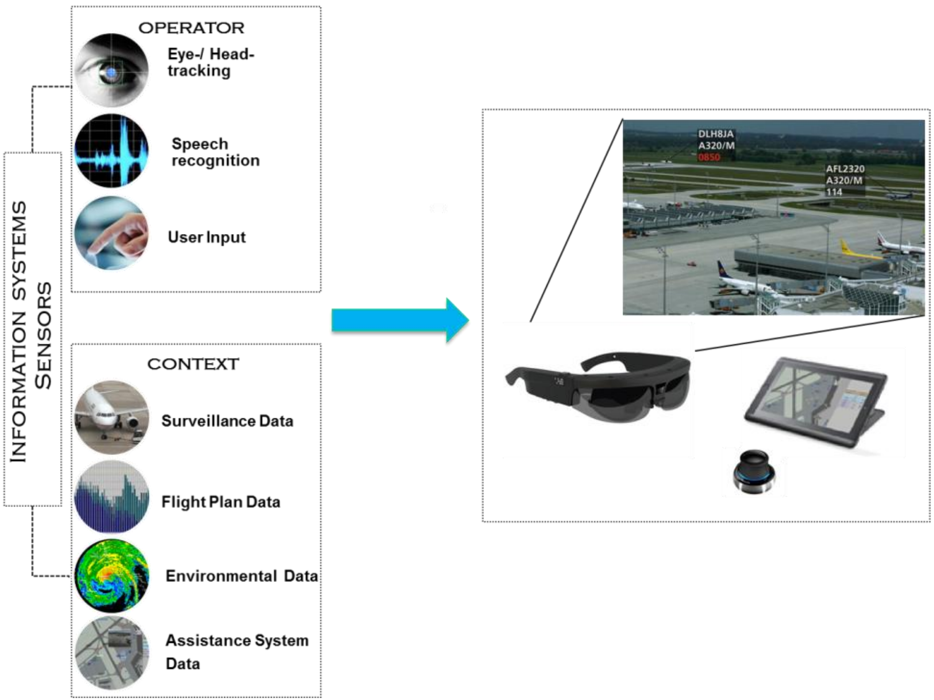

Fig. 1.

Simplified framework of the concept proposed by Gürlük (2016). The adaptive information management is based on information systems and sensors (left). Augmented traffic data is displayed on a wearable (right). Augmented data manipulation is enabled by interaction devices (bottom right)

The expected benefit of the described concept is an information presentation tailored to the individual ATCO informational needs and the specific operational context, hence resulting in a reduction of clutter and informational workload. The ATCOs can also spend more time working head up, thus benefits are also expected in the reduction of search times for information normally presented head down, increased runway safety and situational awareness (Gürlük, 2016).
The work presented in this paper is part of the DLR project Adaptive Controller Support Components (AdCoSCo), which investigates broadly the application of adaptive automation in combination with augmented vision and selected interaction technologies, e.g. automatic speech recognition for the support of air traffic controllers. In order to enrich the proposed concept two sites of the German air navigation service provider Deutsche Flugsicherung (DFS) have been visited. Task Analyses, field observations as well as structured interviews and workshops with tower ATCO have been conducted. The main results of these activities, an information model and adaptive radar label concept, are presented in this paper. The conceptual advancements in this paper focus mainly on context-based adaptation.

3. Method

In order to closely relate the concept with its multi-dimensional adaption model to the requirements of today's operation, a review of controller tasks was performed and interviews with ATCOs were conducted to determine their operational practices and their use of information systems. From these interviews, a model of information requirement (see section 4.1) in relation to the operational environment was derived which is the basis for an advanced concept design, in particular the adaptive radar label concept (see section 4.2).

3.1. Task Analyses

The task analyses were based on the manuals of operation for tower control in Germany. The manual (DFS, 2015) define high level and more concrete tasks for tower air traffic controllers:

- Control of flights operating under visual flight rules (VFR) that fly inside, leave or enter the control zone (CTR) unless under control of the approach control unit,
- Departing and arriving aircraft both under visual and instrument flight rules (IFR),
- Aircraft on ground in the vicinity of the runways.

The tasks are further detailed as follows:

- Observation of all aircraft, vehicle and personnel on the movement areas,
- Issuance of all necessary air traffic control clearances and instructions via radio telephony:
    - Clearance to enter the ctr,
    - Clearance to leave/cross the ctr,
    - Instructions to create a landing and departure sequence,
    - Instructions to line-up on the runway,
    - Take-off and landing clearances.
- Issuance of information for safe, orderly and expeditious operations:
    - Relevant local traffic information,
    - Relevant information about the aerodrome state,
    - Weather information.

Based on those pre-defined high-level tasks, semi-structured interviews were conducted with seven ATCOs at two tower facilities of the DFS. The interviews are helpful in order to better understand the information requirements for the completion of their tasks as well as the relative importance of the different sources of information and the timing of information presentation. As the time for the controller interview was limited, only the following five cardinal tasks for tower controllers were chosen for the interview guideline:

1. Surveillance of movement areas and the airspace (control zone),
2. Determination and control of the take-off sequence,
3. Determination and control of the landing sequence,
4. Take-off clearances,
5. Landing clearances.

For each of these five tasks, the following questions were discussed:

- Which information is required to perform the task?
- During which periods of time before and after the clearance is the information required?
- Is coordination required to perform this task?
- Which instructions have to be issued?
- Is there a difference between daytime and during night time operations?
- Is there a difference between high and during low visibility conditions?
- Do you see a potential to transfer the information to a head up display?

- Do you have any ideas how this situation can be displayed head up and how it can be supported by adaptive automation?

3.2. Field Observations

Parts of the on-site workshops were performed in the cab of the control towers located at the respective facilities. This allowed for an overview over the consoles with the different head down systems as well as a deeper insight into the work of the controllers. Questions and observations could be discussed on site with off-duty controllers, which allowed for an in-depth investigation of the work environment and information requirements of the controllers.

4. Results

In general, the interviews with the ATCOs revealed that the concept of the augmented vision assistance system with adaptive information management (Gürlük, 2016) could be beneficial for tower operations. According to the ATCOs opinion the amount of data and its adaptive information presentation must be carefully designed in order to avoid over-cluttering or produce even more severe problems that could affect operations. The controllers uttered many ideas in which augmented vision based adaptive automation could support them in their work. Their ideas are also reflected in the information model and adaptive label concept, which are presented subsequently.

4.1. Information Model

As a prerequisite for the overall concept design, particularly for the augmented adaptive labels, a model of information requirements for air traffic controllers was derived from the interviews and field observations. The model aims to describe the nature of the different pieces of information controllers require for their work in order to derive whether a piece of information should or should not be displayed in the head up display. The information required by air traffic controllers can be segmented into time critical, non-time critical information and general information.

4.1.1. Time-Critical Information

The first is only required during limited time windows, yet have to be accurate in this time window as they may be dynamically changing. Outside of these time windows, the information is not required. This information includes, but is not limited to:

- Wind direction, speed and gust values,
- Runway visual range (rvr) values (in reduced visibility conditions),
- Distance to go and ground speed for inbound aircraft.

This information is required irrespective of whether the movement is departing, arriving or flying locally.

4.1.2. Non-Time-Critical Information

The *non-time-critical* information usually pertains to certain flights. In a sense, it stays constant for the flight, yet is dynamic insofar as the flight progresses through the airport. Additionally, the controller has to track several flights at any given time and has to correctly attribute the information to each flight. This information includes, but is not limited to

- Callsign,
- Aircraft type,
- Slot times (for departures),
- Departure and destination aerodrome (for departures),
- Planned route (for departures),
- Altitude.

4.1.3. General Information

General information does only vary rarely or not at all. Controllers require this type of information to build and maintain their mental model, however once the information is received and acknowledged, it is not of immediate importance. These information includes, but is not limited to

- runway and airspace configuration
- layout and restrictions on departure procedures
- standing agreements with other air traffic control positions and units

For the design of an adaptive augmented vision system, it seems hence preferable to only display the data that is used the most frequently and/or data that changes dynamically. It was thus decided to choose information from the time-critical and non-time-critical category for the adaptive label concept.

4.2. Adaptive Label Concept

To support the controller, information shall be displayed in the head up display which can be grouped into two categories: information pertaining to individual aircraft or vehicles (e.g. position, callsign) and information valid for the entire airport (e.g. weather data). At the core of the concept are labels that are attached to aircraft in the outside view that convey additional data about the flight. The label type data representation was chosen to keep the look of the head up display close to the look of existing radar displays, in order to help controllers quickly transition to a head up working mode. To avoid clutter and provide the ATCO only with relevant flight data in dependence of the current operational context, a set of labels was developed. Only one label type per time is attached to each aircraft. Each label type conveys a slightly different set of information, tailored to the operational requirements of the controllers.

- **Visual marker:** Aircraft and vehicles are highlighted by suitable visual cue (box, dot or similar) in the outside view. This highlighting is however just a visual cue that an aircraft or vehicle is at that position and does not contain any further information.
- **Concerned label:** This label type attaches the following information to the aircraft: callsign, aircraft type and wake turbulence category.
- **Departure ground label:** For departing aircraft on ground, the label shows the following information adjacent to the highlighting box: callsign, aircraft type and wake turbulence category, departure route, calculated takeoff time (CTOT) if any
- **Departure air label:** Once departing aircraft are airborne, the data content shall be reduced to show callsign, aircraft type and wake turbulence category and the aircraft altitude
- **Arrival air label:** For arriving aircraft on final approach shows the following information adjacent to the highlighting cue: callsign, aircraft type and wake turbulence category, ground speed and distance to the threshold.
- **Arrival ground label:** Once arriving aircraft are on ground, the label displays the following information: callsign and scheduled parking position.

Fig. 2.
Visualization of the augmented label concept: DLH8JA with a departure ground label (left), aircraft with callsign AFL2320 with a concerned label. On the upper right a data block with critical data is displayed (UTC, wind data and QNH)

To satisfy the requirement of identifying air traffic transmitting on the frequency, a visual cue similar to a very high frequency direction finder (VDF) on a radar scope shall be provided to indicate from which direction the transmission is originating. To concatenate the information pertinent to the entire airport, the following data shall be included as overlay data block in the head up display for visual meteorological conditions (VMC):

- Wind data (direction, speed, and gusts),
- Air pressure value (qnh).

For inclement weather conditions, additional data shall be added to this data block:

- RVR values (touchdown, midpoint, rollout),
- Runway friction values.

4.3. Invocation Conditions

To trigger the changes between the labels, invocation conditions or triggers are defined. These triggers may be one or a set of several values or states measured by the adaptive system. If none of the invocation conditions of the other label types are met, no label is displayed.
The concerned label is invoked for a period of time (e.g. 30s) after the aircraft has been transferred by another controller (e.g. ground control) to the tower controller. This information could be derived from a flight strip system or (should it be available) an automated speech recognition system that detects the other controller's instructions. Hereby, this label serves as an announcement that this aircraft will most likely make radio contact in the near future.
The departure ground label is invoked when an aircraft is on ground, scheduled to depart and enters a predefined area on the airport where aircraft usually receive the take-off clearance. This label is displayed however for aircraft that are judged to be the next in the take-off sequence based on the sequence of aircraft on the taxiway, slot times and departure schedule information if available. This trigger is based on flight plan data, ground surveillance radar and departure schedule data if available. Example areas for this solution are depicted in figure 3: the green areas are marking the taxiways leading to the runway thresholds of the departure runways while the red area marks the areas where arriving aircraft will cross.

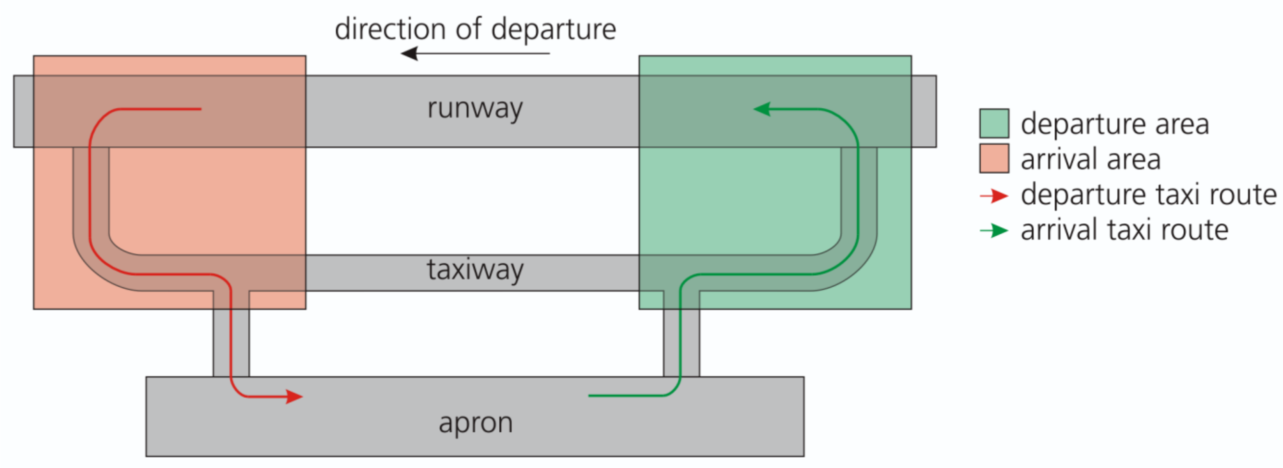

Fig. 3.
Invocation areas for adaptive labels

The departure air label will replace the departure ground label as soon as the system by means of aerodrome surveillance radar detects position information indicating a climb of the aircraft or by means of automatic speech recognition detecting the take-off clearance by the tower controller. The departure air label will display continuously until the aircraft reaches a defined altitude and/or distance from the field (e.g. 5000 feet and/or 8 NM). This requires again data from the radar system.
The arrival air label is presented for inbound aircraft on 10 NM final approach. The possible triggers are the groundspeed information and the flight plan. As for the departure ground label, this label is only displayed for the next inbound aircraft on final approach.
Once arriving aircraft pass a certain threshold speed, the arrival air label is replaced by the arrival ground label, a switching speed could be e.g. 40 knots. This label is presented until the speech recognition senses a handover of the tower controller to the ground controller or the flight strip is closed by the controller in the electronic flight strip (EFS) system.

5. Summary and Outlook

The paper describes the advancement of the concept proposed by Gürlük (2016) in the area of context based adaptive system design. Based on air traffic controllers' feedback during conducted interviews, a wearable head up display with adaptive information presentation seems beneficial with regard to information acquisition and information analysis times. This is the case when only aircraft are labeled with augmented flight data which are actually under the responsibility of the ATCO. Another aspect which promises to reduce controller workload and over-cluttering regards the tailoring of the information requirements to the current operational conditions and the ATCO's needs. As the concept is developed based on feedback and ideas of air traffic controllers to consider the operational reality and covers many of the requirements that the experts have. This concept is developed along the established theoretical frameworks for adaptive systems

(Dorneich & Feigh, 2012) and complies with recommended practises for automation employment in air traffic management (Inagaki, 2003).
While this concept takes into account actual operational requirements, there are still some open questions. Mainly, the concept does not take into account the state of the art of data collection and processing in the ATC environment. Technologies like automatic dependent surveillance (ADS), multilateration (MLAT) or ground radar as part of an advanced surface movement guidance and control system (A-SMGCS) are available today, however are not consistently available or even required for all relevant participants in aerodrome traffic (e.g. ground vehicles).
Future work on this topic should investigate the technical feasibility of augmented vision in the tower environment, especially the usability and display delay. These factors have so far precluded the introduction of augmented reality devices into the tower environment, although all studies indicate that it would be beneficial for the safety and efficiency of the work of tower air traffic controllers. Simulation studies will be conducted this year where parts of the multidimensional adaptation model as well as the augmentation of adaptive radar label into the outside view will be implemented and tested in collaboration with ATCO's from DFS.

AN ECONOMETRIC ANALYSIS OF AIR TRAVEL DEMAND IN MOROCCO

Elmostafa Erraitab[1], Ahmed Hefnaoui[2], Mohammed Moutmihi[3]
[1,2,3] *Hassan II University, Faculty of Economic, Legal and Social Sciences, Mohammedia, Morocco*

Abstract: Given the importance of the air traffic analysis both for airlines and civil aviation authorities, the main aim of this paper is to develop an econometric model to analyze, assess and forecast the air travel demand in Morocco. To select the relevant variables, the all possible regression procedure was conducted. The model containing price index consumer, the gross national product, household final consumption per capita and international tourist's arrivals is the most appropriate model to represent the demand for air travel in Morocco.

Keywords: air travel demand, modeling air travel demand, all possible regression procedure, Morocco.

1. Introduction

Air travel demand modeling is a major determinant of airport planning. In fact, forecasting errors of air travel demand can be very expansive. Underestimate the air traffic demand can cause airport facilities congestion, increasing wait time and inadequate airport facilities. In the same time, overestimate the air traffic demand can induce serious financial problems for airport authorities. Air travel market analysis allows airlines to rationalize its human and financial resources and estimate future needs for recruitment and training manpower. Moreover, air travel market analysis allows airlines to assess objectively the current and future air travel demand by destinations and routes.

Over the period 1970-2000, air traffic has been trending regular evolution. However, once Moroccan government conducted a voluntary policy of air service liberalization, air passenger traffic recorded an average annual growth rate of 9% over the period 2005-2012. Indeed of air traffic increase, the policy of air service liberalization has reconfigured the Moroccan air travel market, there was a massive affluence of low cost carriers (LCC) and diversification of flight supply, as a consequence, the number of low cost European companies' weekly frequencies in the Moroccan market, rose from 600 in 2003 to 960 frequencies in 2009. This increased supply flights require a similar increase in airport facilities. Such a rapidly increase on aviation demand requires significantly accurate tools for short-term and long-term forecasting. Thus, the main purpose of this paper is to develop an econometric model that not only predict traffic but also determine the impact of changes within the economic environment on traffic.

This paper is organized as follows. Section 2 provide the literature review and section 3 presents data source used to analyze and develop an econometric model for air travel demand in morocco. Section 4 describes the chronology of the air traffic development in Morocco. Section 5 presents the determinants of air travel demand in Morocco while the sixth section display a descriptive analysis based on matrix correlation. Section 7 section describes the base model development. Base model run results is provided and commented in section 8. Finally in section 9, conclude the paper.

2. Literature review

The rapid growth of global air traffic has attracted the attention of many researchers and academics in the period 1970-2012, global air passenger traffic achieved an average annual growth rate of 5.4% (The World Bank IBRD-IDA). Studies that explore the air traffic demand has emerged strongly over the past four decades, and an abundant literature dealing determinants of air traffic demand has emerged.

There are several methods to model the air travel demand, ranging from methods base on time series, which can be summarized in two approaches, Box&Jenkins (1976) univariate approach and multivariate approach based on VAR and VECM, until approach based on econometric modelling. Time series power certainly has a strong predictive power, especially in short term, but are limited by their inability to determine the causes of changes in the explanatory variables. They cannot, for example, quantify the impact of rising income on the air travel demand. This question requires the specification and development of an econometric model that links changes in traffic demand with other relevant variables.

The study led by (Jung & Fujii, 1976) is considered one of the pioneering works in terms of estimating the price elasticity of air travel demand, however, this results are significant but not reliable for the following reason : The authors did not consider the differences from one trip to another; in fact, the price elasticity of demand for air travel for a passenger who wants to spend his weekend in another city is not the same as if he has to travel for business. This is confirmed by a recent study by (Callaghan & Tol, 2013) where the travel pattern case is price inelastic.

According to (Lewis & Mitchel, 1990), the quality can be defined as: 'To what extent service fulfills or exceeds the needs and expectations of consumers. Indeed, the quality of air service is an important factor for modeling the air travel demand, this factor was still ignored at several studies that aim to model the air travel demand. (Spence, 1975, cited by ((Ippolito, 1981)), considers that this variable is the key element of product differentiation. Despite the theoretical interest of the variables that represent the level of air traffic services, empirical models for modeling the demand for air passenger traffic have generally assumed that demand is insensitive to the air level service quality (example (De Vany,

[1] Corresponding author: m.raitab@gmail.com

1974). (Jung & Fujii, 1976). In 1975 (De Vany, 1975) caught the omission of air service quality in his model (1975), he integrated flight frequency as an indicator which can reflect the quality of service, although the empirical results for the variable frequency of flights were unsatisfactory, but this study has the merit of including the variable quality of service as a determinant of air travel demand. To take into account the variable quality of service (Ippolito, 1981) has specified the following model:

$$Q = A\exp(bF^2)N^{\beta}\left[(Q+Y)/S\right]^{\alpha} \tag{1}$$

Where; Q represents the origin/destination demand, Y passengers in transit, N flight frequencies, (Q + Y) / S is load factor and S is the average size of aircraft (the number of seats). The estimation results of equation 1 are compatible with the assumptions given by (Ippolito, 1981), the empirical results show that the demand for air travel is positively related to frequency of flights and negatively to load factor. However, the study results (Ippolito, 1981) come from a relatively small sample and carefully chosen to eliminate the theoretical and empirical problems, hence, the study results are related to these study assumptions.

In order to detect the determinants of domestic air traffic in the case of Saudi Arabia, (Abdullah O, Seraj, & Sajjad, 2000) used the technique of stepwise regression to find the best econometric model of the air traffic demand. The authors split the income into several categories; oil-GDP, Private Non-oil GDP, Government Non-oil GDP and total Non-oil GDP. They found that the model containing the explanatory variables as population size and total spending is the appropriate model to explain the demand for domestic air traffic in Saudi Arabia. Neither aggregate income nor any of its components were significantly explanatory of demand for international air travel in Saudi Arabia.

(Alperovich & Machnes, 1994) used permanent rather than current income as relevant variable which determines the demand for international air travel demand, the authors have shown that the main source of misspecification for last studies is the omission of variables representing the wealth of the consumer. The authors fond that demand for air travel out of Israel is price-inelastic and income-elastic, the results of their study support the fundamental assumption that the wealth of consumers is the key determinant of demand for air travel. The authors divided the consumers' wealth in two categories; financial and non financial assets. They argue that an aggregate income variable which combines income from different sources may be inadequate, since propensity to travel may be different according to the source of income. The main innovation of this paper is that ((Alperovich & Machnes, 1994) found that wealth variables display the anticipated positive signs and highly significant. Thus, the demand for air travel depends on consumer wealth and not only the current income.

In order to evaluate the economic impacts of permitting charter flights on tourism in Israel, (Haitovsky, Salomon, & Silman, 1987) have specified a two-equation model, one for overall tourism demand and the other for tourism demand addressed to scheduled flights. The resulting model has shown that regular flights demand is price-elastic in the presence of charter flights, that being said, the permitting of charter flights induces a fall in air fares of regular flights as a result of competition, and this indirectly promotes tourism in the countries that liberalize charter flights.

3. Data source

The data used to estimate the model have been taken from different sources. Data on Moroccan air travel are from Moroccan civil aviation authority database. The data on Moroccan social and economic characteristics that could affect demand for air traffic were taken from World Bank collection of development indicators (The World Bank IBRD-IDA).

4. Moroccan air travel developments

The geographical location and socio-political stability in Morocco, are considered as a significant factors to an important air traffic growth. Morocco is the first North African and seventh African country, with whom the United States signed an open skies agreement since 2002, in addition, indeed, in 2006, Morocco has signed with the European Union an open sky agreement, it was the first of its kind among the agreements between the European Union countries and non-EU countries.

Following the voluntary policy of air service liberalization conducted by the Moroccan government, the volume of air traffic passenger has increased from 6.7 million passengers in 2002 to 7.7 million passengers in 2006 and 15.2 million in 2012, realizing an average annual growth rate of 9% over the 2004-2012 period.

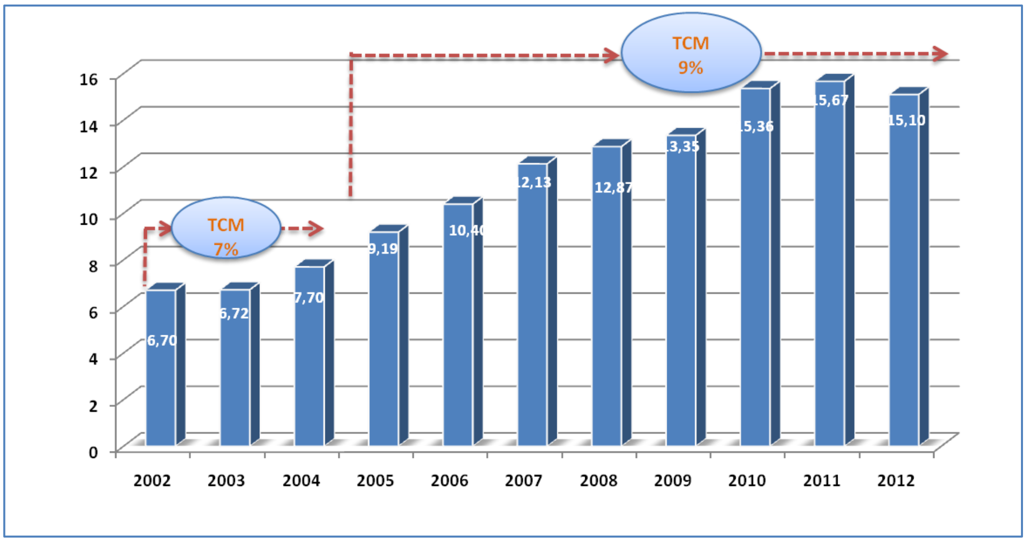

Fig. 1.
Air passenger traffic evolution over the 2002 à 2012 period
Source: Author's calculations based on Moroccan Civil Aviation Authority data.

Airlines have strongly increased their supply since 2003, all types of airlines together, they have increased the seat supply over the period 2003-2009 by 1.685 additional monthly frequencies.

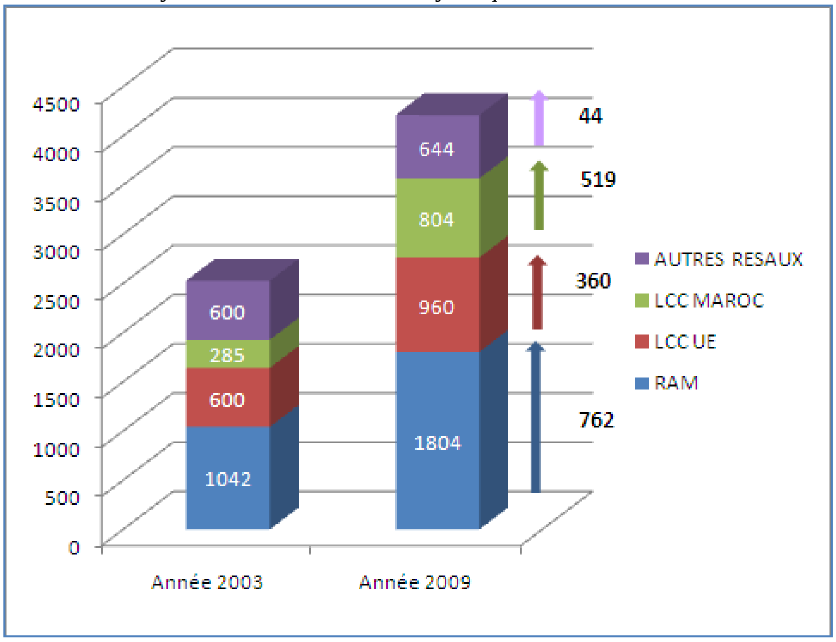

Fig. 2.
Supply growth of the Airlines that serve Moroccan air travel market
Source: Author's calculations based on OAG data, may 2003-2009.

Taking advantage of the open sky agreement signed between Morocco and the EU in 2006, several low-cost airlines have begun to serve the Moroccan destination. Thus, the European low cost carriers alone have increased their monthly frequencies of 360 additional frequencies between 2003 and 2006, in turn, followed the trend, the Moroccan LCC increased their monthly frequencies of 519 frequencies over same period.

5. The determinants of air travel demand in Morocco

The literature review allowed us to identify several factors that impact the demand for air travel, these factors can be summarized into two categories; The first affecting air transport supply and second affect demand side.
The factors that affect the air transport supply sides include regulatory framework, airline strategy in terms of number and frequency distribution over the day and over the week, the level of service quality in terminal and during the flight, infrastructure capability and competition from the other transportation modes.
Factors that impact the demand sides of air travel include household wealth (Alperovich & Machnes, 1994), the population size and total expenditure (Abdullah O, Seraj, & Sajjad, 2000) and the purpose of travel (De Vany, 1974).
The examination of literature review allowed us to select a list of air travel demand explanatory variables.

Modeling air travel demand in morocco will enable us to decide on the significance of each variable. Before starting the conception and estimating the econometric model, we begin with a correlation analysis of the used variables list.

5.1. Correlation matrix analysis

Table 1
Correlation matrix of the variables considered to explain air travel demand in Morocco

	PAX	GDPC	CPI	EGS	FCE	FDI	FF	GNI	HFCEPC	ITEP	ITET	ITNA	ITR
PAX	1	0,96	0,97	0,92	0,88	0,68	0,94	0,92	0,97	0,94	0,98	0,98	0,95
GDPC		1	0,99	0,95	0,85	0,77	0,96	0,97	0,99	0,96	0,96	0,99	0,97
CPI			1	0,96	0,88	0,76	0,97	0,97	0,99	0,97	0,97	0,99	0,97
EGS				1	0,85	0,81	0,95	0,95	0,93	0,95	0,89	0,95	0,98
FCE					1	0,65	0,87	0,90	0,84	0,87	0,87	0,90	0,87
FDI						1	0,70	0,77	0,76	0,77	0,69	0,73	0,84
FF							1	0,94	0,95	0,94	0,93	0,96	0,95
GNI								1	0,95	0,94	0,92	0,97	0,95
HFCEPC									1	0,96	0,98	0,98	0,96
ITEP										1	0,96	0,95	0,96
ITET											1	0,97	0,93
ITNA												1	0,96
ITR													1

Where GDPC : GDP per capita (constant 2005 US$), CPI: Consumer price index (2005 = 100), EGS: Exports of goods and services (constant 2005 US$), FCE: Final consumption expenditure (constant LCU), FDI : Foreign direct investment, net inflows (BoP, current US$), FF : Flight Frequency, GNI : HFCEPC : Household final consumption expenditure per capita (constant 2005 US$), ITEP : International tourism, expenditures for passenger transport items (current US$), ITET : International tourism, expenditures for travel items (current US$), ITNA : International tourism, number of arrivals, ITR : International tourism, receipts (current US$).

The correlation matrix shows that there is a high correlation between on the one hand, the consumer price index Household final consumption expenditure per capita, tourist spending, the number of international tourist arrivals and air traffic on the other.

One can observe that there is a strong correlation between the regressors variables and the dependent variable, it is a sign of collinearity presumption between independent variables. The presence of collinearity between the independent variables induces an increase of some estimated coefficients variance, instability of least squares coefficients estimator, and in case of perfect collinearity, the X'X matrix of regressors is singular, therefore it would be impossible to estimate the coefficients. Considering the problems that can cause the presence of collinearity phenomenon between the regressor variables, we must first check its presence and provide a procedure to treat it.

Farrar and Glauber test allows detecting the presence of collinearity. Appendix 1 gives program details for calculating the Farrar and Glauber test in Eviews.

According to the test results, it was found that the calculated chi-square is greater than the theoretical chi-square, $\chi_c^2 > \chi_{th}^2$,in this case we reject the null hypothesis H0 of no collinearity and alternative hypothesis H1 is accepted, there is a collinearity presumption among explanatory variables for air travel demand in Morocco.

As mentioned above, when there is an exact linear relationship between two or more explanatory variables, the linear regression equation becomes insoluble, that being said, one should keep only one of the explanatory variables among those that are perfectly correlated. This kind of collinearity treatment is especially true in cases where the correlated variables represent the same reality, when deleting one or several collinear variables, the remaining variable capture the effect of other removed variables.

5.2. Base model development

To find the right mix of explanatory variables, the all possible regression procedure for selecting independent variables was conducted (the detailed procedure program in Eviews is in Appendix 2). The procedure is to calculate all possible regressions or (2^k-1) regressions, in our case; we have to estimate 4095 models. Among 4095 models, we have to choose the appropriate model. The criteria for selecting the right model are the following:

a) All of the model coefficients must be significantly different to 0 and ,
b) The appropriate model must have the highest R^2.

The procedure of selecting the relevant variables shows that the best model is as follows:

$$Y_t' = 11818357.89 - 168393.3848 * x_{2t} - 1.975783646e-005 * x_{7t} + 7502.938943 * x_{8t} + 2.624283968 * x_{11t}$$
$$(-2,30) \quad (-4,66) \quad (2,94) \quad (8,02) \qquad (2)$$

Adjested $R^2 = 0.990964$

The values in parentheses represent the t-statistics of estimated parameters.
The R-squared (R^2), which can be interpreted as the fraction of the variance of the dependent variable explained by the independent variables, shows that there is a high linear relationship between air passenger demand in Morocco and the relevant variables chosen by the procedure (appendix 2), indeed, the F-statistic p-value, which is the marginal significance level of the F-test, is less than the significance level ($\alpha = 5\%$), so we reject the null hypothesis that all of the regression coefficients are zero.
Generally, when the time series are used, there is always a risk of falling into the error serial correlation phenomena when model is estimated by the OLS estimator. Therefore, before using the estimated model for statistic inference (eg, statistical hypothesis tests and projections), we should generally examine the residuals for evidence of serial correlation. Generally, according to ((Johnston & DiNardo, 1997), with 50 observations or more, and only a few independent variables, a DW statistic below about 1.5 is a strong indication of serial correlation of positive first order serial correlation.

Table 2
Correlogram of residual squared

Source: Author's calculations based on OAG data, world bank indicators database and Moroccan civil aviation authority database.

The correlogram for the first 10 lags from equation (2) does not show a significant serial correlation in the residuals. This result is confirmed by the Breusch-Godfrey LM test for serial correlation of residuals.

Table 1
Test Breusch-Godfrey Serial correlation LM Test

F-statistic	0.088754	Probability	0.915784
Obs*R-squared	0.296499	Probability	0.862216

Source : Author's calculations based on OAG data, world bank indicators database and Moroccan civil aviation authority database

The test does not reject the hypothesis of no serial correlation up to order two, The p-value of F-statistic and Obs* R-squared is well above the threshold of significance α 5%.

6. Results comment

By looking into the results of regression analysis of equation (2), it's found that variable X_2, which represents the effect of Consumer price index in Morocco, - holding other thing the same, has a negative and significant effect on air travel demand in Morocco. As such, the Consumer price index reflects changes in the cost to the average consumer of acquiring a basket of goods and services that may be fixed or changed at specified intervals, such as yearly. The Laspeyres formula is generally used. The consumer price index is usually calculated based on periodic surveys of price basket consumer. As shown in the regression results of equation (2), as consumer price index goes up by one percentage point, on the average, demand for air travel down by 16.8 million passengers. This result is consistent with those found by (Alperovich & Machnes, 1994), which showed that the air travel demand depends on the consumer total wealth. The

inflation increase, as measured by consumer price index, increases artificially the basket price of goods and services purchased by a standard consumer, as a result, the consumer wealth, especially the current income, is modified.
Gross National Income (GNI), represented by the variable X_7, GNP under the old appellation, which represents the sum of value added produced by all residents plus any taxes product (less subsidies) not included in the production valorization, plus net receipts of primary incomes (compensation of employees and property income) from abroad. In other words, this variable is the sum of value added produced by national, whether in the country or abroad. According to the Moroccan tourism observatory, almost 95% of the air passengers are foreign tourists or the Moroccan living abroad. Therefore, it seems that the air travel demand in Morocco is influenced much more by macroeconomic aggregates emitting countries tourists than by economic fundamentals of the national economy. Although the GNP variable is significantly different from 0, his impact is very small, its coefficient does not exceed the value of 0.0000198.
Household final consumption expenditure per capita, represented by the variable X_8, have a positive and significant coefficient, the t-Student statistic value of his coefficient is 2.94, meaning that true X_8 coefficient is different from 0. This variable captures the effect of Household final consumption expenditure per capita, represented by the market value of all goods and services, including durable products (cars, washing machines, and home computers), purchased by households. In other words, the evolution of this variable reflects the standard of living of households, an increase in final consumption expenditure of households indicates an increase in household wealth. The X_8 coefficient sign is consistent with those found by (Schafer & David G, 2000), indicating that as far as personal income tends to increase, the people mobility increases accordingly by turning to other faster and more expensive modes of transportation. Thus, our results are consistent with what we found in the literature review on the air travel demand, the travelers mobility depends strongly on the passenger wealth. Nevertheless, the impact of this variable is a handle with care, its impact is very small, as X_8 goes up by one percentage point, - holding other thing the same, demand for air travel increased only by 0,7 million passengers. This confirms what we have said above, the air travel demand in Morocco largely come from international tourists and Moroccan living abroad.
The X_{11} variable, represents the international tourism, number of arrivals. This variable include international inbound tourists visiting Morocco, ie, the number of tourists who travel to Morocco for a period not exceeding 12 months and whose main purpose in visiting is other than an activity remunerated from within the country visited. Under this definition, the Moroccan living abroad are also considered as foreign tourists.
The X_{11} variable has positive and strongly significant coefficient, this result is in line with those found by (Haitovsky, Salomon, & Silman, 1987), which concluded that the liberalization of charter flights in Israel, due to generation effect, forces scheduled air fares down and encourages improvement in the level of service; thus it indirectly favours tourism to countries permitting charter flights. Passengers on business trips or for other non-tourism purposes are price insensitive, but leisure purpose passengers are highly price sensitive.
The Moroccan government has adopted a deliberate policy of air service liberalization, it creates more competition between airlines, and such competition is played primarily on air fares. The introduction of low cost carriers in Moroccan air travel market induced lower air fares, increasing flight supply and diversification of destinations.

7. Conclusion

In this paper, an attempt is made to develop and estimate an econometric model explaining the air travel demand in morocco. The econometric model will be used as a tool to analyze and forecast the air travel demand, through establishing statistical relationship between selected demand-influencing factors and the corresponding level of traffic in morocco. In order to selecting the relevant variables, initially, we used correlation analysis, and then, we used a procedure that estimates all possible variables combinations and then choose between them the best model that satisfies the constraints required by the procedure.
We find that the model containing price index consumer, the gross national product, household final consumption per capita and international tourists arrivals is the best model. Thus, it seems that air travel demand in Morocco is dependent of socio-economic characteristics of transmitter States tourists.
The Moroccan civil aviation authorities and airlines, who want to deserve the Moroccan air travel market, can be based on this model to assess and predict the air travel demand in Morocco.

AIRPLANE CABIN FOR ALL

Petra Matzenberger[1], Helmut Lemmerer[2], Bernhard Rüger[3]
[1,3] *Vienna University of Technology, Institute of Transportation, Research Centre of Railway Engineering, Traffic Economics and Ropeways, Vienna, Austria*
[2] *Vienna University of Technology, Institute of Transportation, Research Center of Transport Planning and Traffic Engineering, Vienna, Austria*

Abstract: Today's aircraft cabins often did not comply with the needs of people with reduced mobility. Due to several regulations it was expected that, just like railways already had, arrangements in air traffic would be set to improve accessibility for these people in aircraft cabins. The aim of our project Cabin4All was to implement and evaluate steps that provided an added value for disabled persons. These steps should also be efficient enough for airlines. With the help of a large survey at the airport in Salzburg it was possible to get a good overview of which problems different kinds of people had. Moreover, several networking workshops were held to bring together representatives from aircraft industry, railway industry and potential passengers and define the specific requirements.

Keywords: air traffic, cabin, accessibility.

1. Introduction

Due to the fact that there are already valid laws and additional national and international laws and EU-regulations against discrimination currently being prepared it is expected that, just like railways already have, there will be stricter requirements for accessibility in European air traffic in a few years. Currently there are several aides for people with reduced mobility in air traffic but during the flight only some needs are being met yet. Flight industry is increasingly caught between necessary equipment for peoples with special needs and the economic pressure to use all available space in an air cabin to maximize seats.

The aim of the project Cabin4All is to set up a clearly defined requirement catalogue as a key foundation for future aircraft development based on technological and ecological feasibility under consideration of what people with reduced mobility need. Many requirements have already been implemented in railways, so it´s easy to use the specific know-how for flight industry as well. The Cabin4All project is an exploratory study that primarily presents the cross-linkage between flight industry, railway industry and disabled persons. Under consideration of valid regulations and safety requirements the project should show which steps are viable and which steps should not be pursued.

2. General requirements of persons with reduced mobility

The study "European Standardisation of Accessible Tourism Services" found out that there are some lacks in EU legislation on accessibility. Moreover, most standards focus on technical specifications and few on service and quality management. Access Standards show considerable variation by European countries in the functional requirements they prescribe and in the dimensional and design requirements. (European Network for Accessible Tourism, 2009)

The right contact and the right manner with people with reduced mobility is one of their requirements. For this reason it is important to control the quality of the service management. Moreover it should be included in the user's requirements. Concerning the EU legislation 1170/2006 travellers with reduced mobility have the right to aides without any charge and without showing any medical reports. A report must only have to be shown if there are any risks concerning the health and security of the traveller, of other travellers or the boarding crew. (European Commission, 2012)

2.1. Situation concerning the airplane

Many different problems in a report concerning the air-travelling situation of persons with reduced mobility were mentioned by the European Commission:

"Disabled people and people with reduced mobility continue to come across many problems when travelling by air: a lack or unequal level of quality of service in Europe; too often unjustified refusals or restrictions of reservations or boarding based on unclear safety reasons; inconsistencies in the treatment of passengers who need medical oxygen onboard; limited level of awareness of passengers regarding their rights; limited percentage (around 40%) of pre-notification of their needs before travelling; lack of harmonisation of the interpretation of the regulation by national enforcement bodies; and lack of effectiveness in the treatment of complaints." (European Commission, 2011)

To obtain similar options as other travellers, certain assistance and facility elements have to be offered for persons with reduced mobility. It is illegal that this support cost anything due to non-discrimination rules. The service components which have to be achieved are located in the airport manager's authority on the one hand, and on the other hand, they have to be guaranteed by the cabin crew. The cabin crew is responsible for safety regulations and also for comfort. Safety regulations are, for example, on-board-emergency-equipment like seat belts, oxygen masks and life jackets. The

[1] Corresponding author: petra.matzenberger@tuwien.ac.at

catering with snacks and drinks belong to the comfort. Generally, the cabin crew is responsible for the safety of all passengers. But they do not have to support anyone with the food intake or with any medical issues. If someone needs support in general or help for the transfer from the seat to the toilette for example, the cabin crew has to help. In principle, the airline company or travel agency has the right to refuse the reservation or the journey if the safety regulations cannot be observed. If the person with reduced mobility gets the permission to travel, he/she usually has to inform the airline company at least 48 hours before travelling. The assistance at the airport is regulated in the EU guideline 1107/2006 and has to be free of charge.
According to the practical field, it would be better for people with reduced mobility to inform the airline at least one week before their travel date because the airport also needs some time for preparation and even handling wheelchairs can vary at all airports. (Mobilista, 2015).
Therefore the airports and the airline companies have categories, so called Special Service Request Codes (SSR). With the help of these codes it is possible to differentiate between different assistance needs and aid utilities. Most of the time, the categories are consistent across different airports and airline companies but vary in detail and amount. (Porter Airlines, 2016).
As an example the categories or codes of the Vienna Airport are mentioned as follows (Vienna International Airport, 2015; Vienna International Airport, 2016):

- WCHR (wheelchair – ramp): Passenger is able to walk long distances and climb stairs. He/she can move unaided in the cabin and negotiate aircraft steps. Help is required to/from air craft,
- WCHS (wheelchair – steps): Passenger cannot negotiate aircraft steps but can move unaided in the cabin,
- WCHC (wheelchair – cabin seat): Passenger is completely immobile and must be accompanied to/from his/her cabin seat,
- DEAF (deaf – passenger): Passenger with hearing or hearing/sight impediment,
- BLND (blind – passenger): Passenger with sight impediment,
- BLND/DEAF (blind and deaf passenger): Blind and deaf passenger, who can move only with the help of an accompanying person,
- DPNA (disabled passenger needing assistance): Disabled Passenger with intellectual or development disability needing assistance.

2.2. Situation concerning the train

The equality-law of disabled persons has had to be executed since 2016 concerning the situation of people with reduced mobility in the train. New railway carriages will only be bought with the equipment and design according to the standard of the relevant legislation. Old, non-barrier-free railway carriages which modification would not be economically reasonable will gradually be taken out of service.
Concerning accessibility current elements of the railway carriages are:

- Entrance: lifting devices, low floor wagons, boarding ramp, wide doors, call buttons for assistance during entry and exit,
- Parking positions for the wheelchair including plug sockets to charge the battery of electro wheelchairs.
- Folding tables,
- Identification markings in high contrast of handles and grips, package storage, stairs and door handles,
- Toilet: suitable for wheelchairs, tactile elements, emergency buttons, helplines and automatic sliding door,
- Information systems for the passengers: acoustic irradiation (voice mails or train staff), visual announcement (“2-senses- principle” – shown in figure 1),

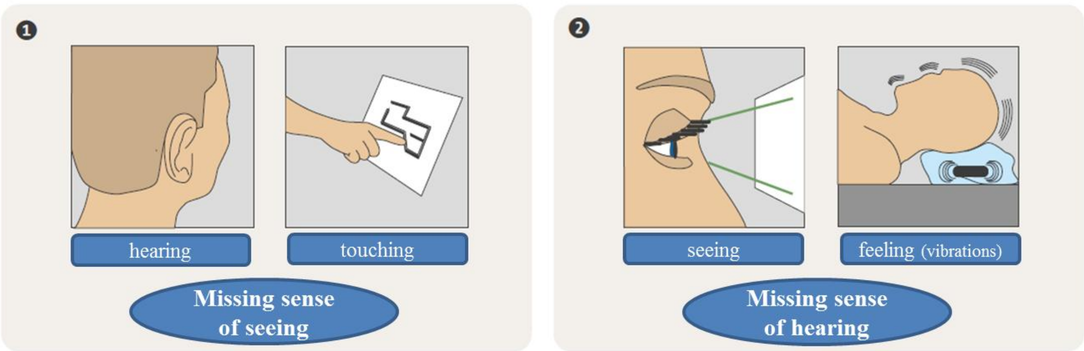

Fig. 1.
2-senses- principle
Source: Kalamidas (2006)

- Tactile elements: guidance system to the toilet, SOS-technology, guidance system to the exits, elevated buttons for entrance and exit doors, identification marking in high contrast for important infrastructure, sensor-controlled internal doors, tactile pictograms. (ÖBB-Holding, 2015)

Concerning the applicability of these elements in airplane cabins it must be said that it is not possible to transfer all of these elements because the stress capability of facilities in airplane cabins are different. For example, it is unfeasible to use the own wheelchair as a seat during the flight. Another obstacle for the use of one's own wheelchair is the width of 50 cm of the aisle in the airplane.

3. Method

One main part of the project Cabin4All was a survey at the waiting area of the airport in Salzburg and an online questionnaire. 1790 people were questioned at the airport Salzburg and 507 online. With the help of the survey at the airport it was possible to get an opinion of the average travellers with and also without reduced mobility and about their evaluation of accessibility in the airplane cabin. The link of the online questionnaire was especially sent to organizations and associations of persons with reduced mobility. For that reason a higher number of these persons took part online. The questionnaire included questions of different parts of the airplane cabin which the questioned people had to evaluate concerning satisfaction and problems. The entrance and exit of the airplane, the corridor of the cabin, the toilets, the seat, the storage of the cabin luggage and the airplane cabin in general were evaluated. The data analysis was done with the program SPSS 22. Figures and graphs were made by the program Microsoft Excel.

4. Results

4.1. General data

From the 1790 questioned people at the airport Salzburg, 58% were male and 42% female. Most of them were between 30 and 59 years. 83% of the questioned persons indicated that they had normal weight. The body height of the questioned people could be seen in figure 2.

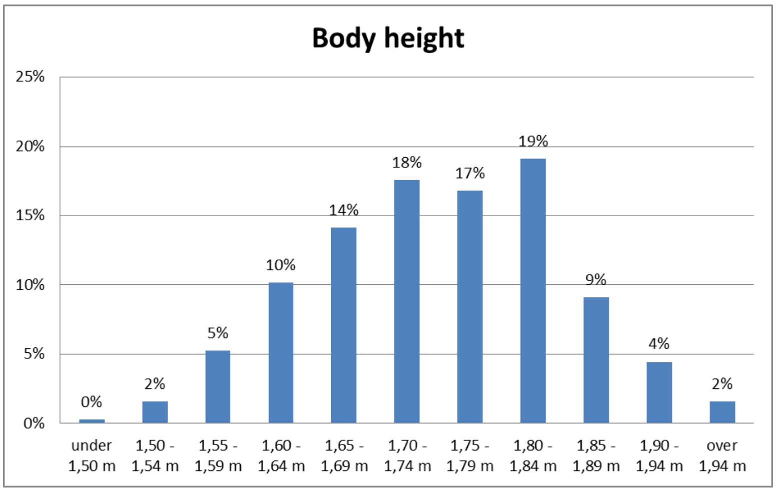

Fig. 2.
Body height of the questioned person at the airport Salzburg

16,5% of the questioned people answered that they had one or more disability. In comparison to the Austrian average, where according to the Federal Ministry of Social Affairs 20,5% of the population have a disability, it is visible that there are less handicapped persons at the airport (Leitner & Baldaszti, 2008). The 20,5% doesn't include pregnant people and people with little childen! Moreover, this percentage refers to private households. Persons in institutions are not included. As a result the number of highly disabled people is underestimated. (Bednar et al, 2008)

4.2. Requirements and problems of persons with a wheelchair

Figure 3 shows a dissatisfaction ranking of the different parts of the airplane cabin. Summing up this ranking, it is obvious that the toilet is the biggest problem of persons with a wheelchair. These results are from the online questionnaire.

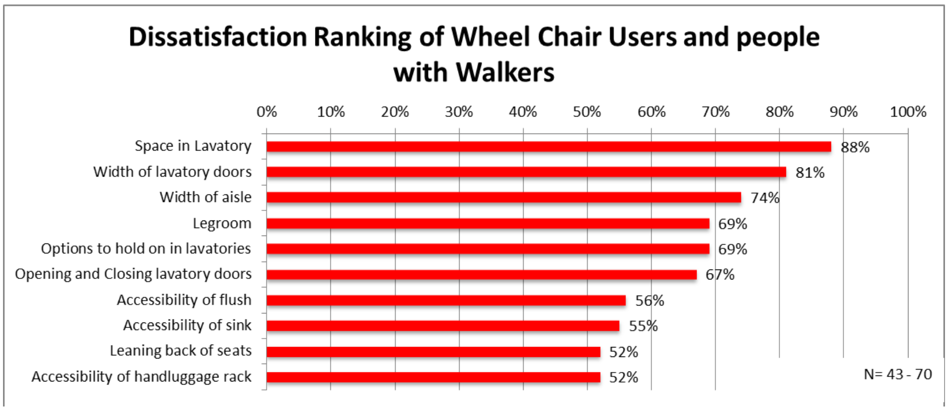

Fig. 3.
Dissatisfaction ranking of persons with a wheelchair or a walking frame

Concerning the problems of wheelchair users in the airplane cabin they answered that they especially had problems at their seats. For example, 67% of the questioned persons said that they had problems with clapping back the seat and 46% said that they had problems with the legroom. But the amount of participants was low (n=8-13) concerning the questions about the problems.

4.3. Requirements and problems of persons with visual handicaps

Most of the persons with visual handicaps said that they were unsatisfied with the seat. They also said that they had most of their problems with the seat. One eye-catching point is that visual handicapped persons had problems with the information through announcements (18%). This kind of information is probably very important for people with visual handicaps. That could be the reason why it should work very well for them. Acoustic irradiation is one element where the airplane could use the guidelines of the railway.
In Figure 4 and 5 it is possible to see the dissatisfaction rankings and the most frequent problems of persons with visual handicaps.

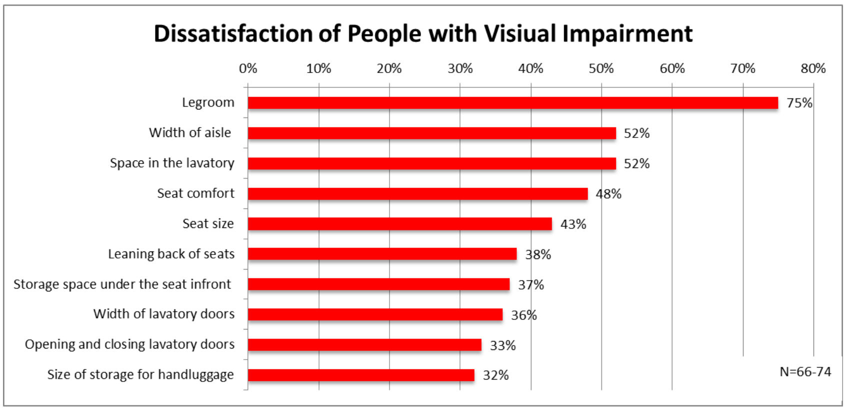

Fig. 4.
Dissatisfaction ranking of persons with visual handicaps

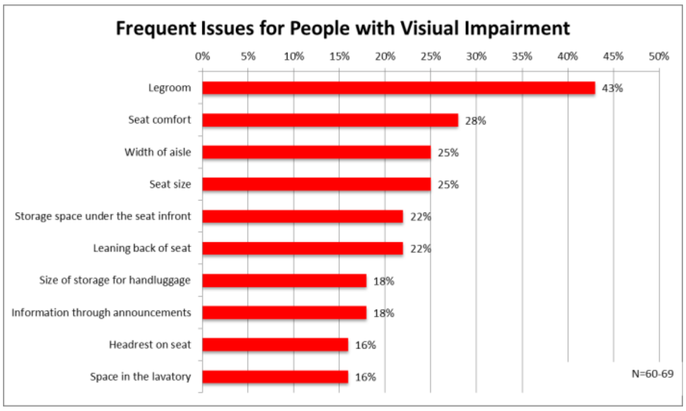

Fig. 5.
The most frequent problems of persons with visual handicaps

4.4. Requirements and problems of persons with little children

Persons with little children on their hands or with a pram are also persons who are hindered. That is why this group was questioned as well. In principle this group showed a higher dissatisfaction in comparison to other groups. The most dissatisfying element was the seat. Especially the legroom (79% were not satisfied), the comfort of the seat (63% were not satisfied), and the size of the seat (53% were not satisfied) were dissatisfying. Moreover, the aisle width was not satisfying for 63% of the questioned persons with little children. More results are showed in figure 6 and 7.
Concerning the situation in the train there are less problems with the legroom or the aisle width. There are guidelines suggesting that there should be a children area in each train. Moreover, there should be enough space at the entrance to turn around a pram or a wheelchair. Concerning recommendations the entrant area should be at least 150 x 150 cm (BMVIT, 2009). This is not feasible in the plane because there they have space issues.

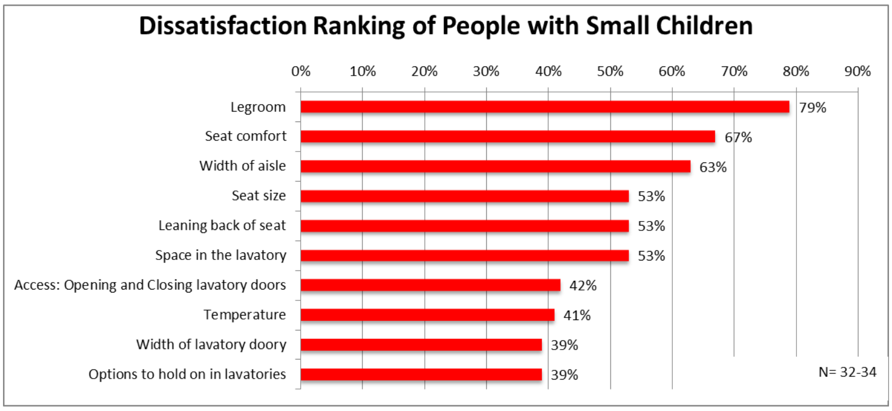

Fig. 6.
Dissatisfaction ranking of persons with little children

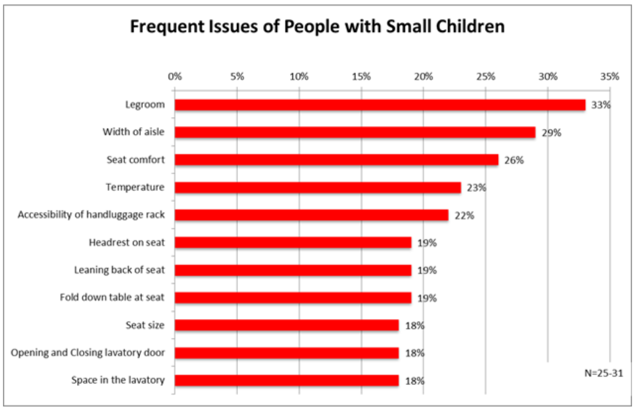

Fig. 7.
The most frequent problems of persons with little children

4.5. Requirements and problems of special groups (age, gender, body height and body weight)

Body weight
All in all, overweight people were less satisfied with the cabin than people with normal weight or underweight. They had the most dissatisfaction with the legroom. 70% answered that they were not satisfied with the legroom. Other dissatisfying elements were the space in lavatories (55%), the seat comfort (51%) and the seat size (49%). It was obvious that these dissatisfying elements were increasing with body weight. Overweight people had more problems with the seat than people with normal weight or underweight. 37% of the questioned persons with overweight answered that they had problems with the legroom. 22% of them had problems with the seat comfort.
Concerning underweight people, it is eye-catching that they were more satisfied in general than people with normal weight and overweight. One dissatisfying element of underweight people is the temperature in the cabin, where 31% were unsatisfied. Moreover, the temperature was also the biggest problem of underweight people. 29% had problems with it. Another eye-catching point is that underweight people had problems with the handle and grip options. For example, 18% of these people answered that they had problems with the handle options in the toilet.
Body height
In summary, tall people had more problems and a higher dissatisfaction than small people. The biggest problem of tall people was the legroom. 66% of persons who were over 1,89 metre tall had already had problems with the legroom. Actually, 87% of them were unsatisfied with the legroom. By the way, the seat comfort was also decreasing with the body height. Tall people were also unsatisfied with arm rests (49%) and neck-rests (48%) of the seat. Interestingly, Tall

people (over 1,89 metre) (32%) as well as small people (under 1,60 metre) (22%)were less satisfied with the accessibility of the sink than persons with average body height. Other dissatisfying elements of tall people were the seat size (57%) and the space in the lavatory (52%).

Small people (under 1,60 metre) had a bigger dissatisfaction with the accessibility of the hand luggage rack than tall and average-size people. 38% of them were unsatisfied with the accessibility of the hand luggage. Actually, 32% of the small people had already had problems with the accessibility of the hand luggage. Interestingly, small people (31%) were also more unsatisfied with the size of the storage of the hand luggage than the others. Moreover, the neck-rests of the seats showed a higher dissatisfaction with small people (30%). One more dissatisfying element of small people is the temperature. 31% of them were unsatisfied with this element and 18% of them had already had problems with this.

Age

Concerning people of the age of 70 years and older, it is eye-catching that they had in general a higher satisfaction but more problems than younger ones. Biggest problem and dissatisfying element of the elderly is the legroom. The group of the 70-year-old-ones and older-ones also had problems with the information through announcements. This is the only element where the elderly showed a higher dissatisfaction than the younger age groups.

Gender

Concerning the difference between men and women, it is obvious that men were much more unsatisfied with the seat than women. Maybe the reason is that they are taller than women. Most dissatisfying element of men was the legroom (71%). Concerning women it was the same, but only 65% of the women were unsatisfied with it. With the legroom men and women also had the most problems and also in this case men (32%) had more problems than women (24%). Typical women’s problems were the temperature (19% of all women had had problems with it) and the accessibility of the hand luggage rack (16% of all women had had problems with it). Also the dissatisfaction of these elements was higher with women (temperature 34% and accessibility of the hand luggage rack 22%) than with men.

4.6. Short-term and long-term service components

All in all, there are a lot of areas in the airplane cabin which could be modified concerning accessibility. A lot of short-term and long-term service components have to be changed to obtain a barrier-free airplane cabin. Some ideas for short-term and medium-term improvements are shown in Table 1.

Table 1
Ranked ideas for short-term and medium-term improvements

Ranking	Idea
1.	Mobile application - assistance
2.	Guidance system for visually impaired
3.	Accompanying person
4.	Staff training
5.	Bi-sensory information
6.	Special cutlery, tableware, tray
7.	Communication supporting items (symbol or card set for showing)
8.	High-contrast elements (especially in the toilet)
9.	Pre-information about special needs
10.	Triangle handle

5. Conclusion

Altogether, there are similar problems and requirements within the different groups of disabled persons according to the survey. Afterwards there are the top five problem areas which were mentioned by the questioned people:

- Legroom,
- Comfort of the seat,
- Space at the toilet,
- Aisle width
- Clapping back the seat.

The problems legroom and comfort of the seat were definitely the leading areas. In the project Cabin4All the comfort of the seat has a less important part because it is more a comfort criteria than a real problem. The legroom at the seat could be a real problem of certain people, for example of wheelchair users, tall persons or persons with an injury of the legs. Unfortunately, this result is unlike the actual trend of the flight business because at the moment the space between the seats is getting smaller and smaller. For example, the Austrian Airlines has reduced the space between seats at the end of 2015. Concerning the clapping back of the seat the reduced or changed space are probably the main problems. Especially for blind people or people with visual handicaps and wheelchair users the reduced or changed space could become a real hindrance.

The topic toilet in the airplane and especially the space at the toilet is the main problem of wheelchair users. Also the head of the stewardesses of the Austrian Airlines mentioned this problem in an interview. Most of the time wheelchair users are not able to use the toilet without the help of others. Especially due to less space and this makes it impossible for some of the wheelchair users to even use the toilet. From the stewardess's view the transfer of the wheelchair user to the toilet is another important problem. Often the disabled persons have no auxiliary persons with them. In the worst case, the cabin crew has to ask another passenger to help them with the transfer.

Travellers who have problems with the sensory organs are, on the one hand, persons with visual problems and, on the other hand, also persons with hearing impaired. One of the main problems for this group is to get information. This is the reason why announcements should be given in a 2-senses- principle . This is also one of the guideline points of the train.

In addition, there are some other guideline points for the railway system which could be implemented in the airplane system. For example, the train staffs are getting taught about handling disabled persons (ÖBB-Holding, 2015).

This should also happen with the cabin crew. In addition, the guideline for a barrier-free train says that 10% of the seats in a passenger train should be marked for persons with reduced mobility. The seats should be near the entrance and should be standardized across all cabins. (BMVIT, 2009) These are some guideline points which are also implementable in the airplane.

All in all, there are a lot of areas in the airplane cabin which could be modified concerning accessibility. Concerning this survey the best ideas for short-term and medium-term improvements were a mobile application-assistance and a guidance system for visually impaired.

PASSIVE RADAR SYSTEM FOR SLOVAKIA

Nikolas Žáčik[1], Andrej Novák[2]

[1,2] The University of Žilina in Žilina, TheFaculty of Operation and Economics of Transport and Communications, Žilina, Slovakia

Abstract: The main problem in general aviation is still the rapid rising level of congestion in the airspace all over the world. It may cause a problem with the plane accommodating, controlling and plane tracking in the airspace with actually non-upgraded land facilities. This topic is a conclusion of 5 years long research about performances of radar technology in general. The main idea of this topic is to give solution to increasing tracking capacity in the airspace for very long time, substantially lower price in the short period of time with sufficient precision for safety increase. For this task we found out that one of the best technologies is the passive surveillance technology, previously used just for military operations but nowadays still more consulted in the civil sector. This article presents the findings from five years research in cooperation with company ERA. The second part of topic solved in the article is theoretical concept of building up the new radar network based on passive radar technology in Slovakia. Article shows the advantages and disadvantages of this passive radar architecture, in comparison with currently used primary and secondary radar network. The research is applicable as a theoretical base for all other countries, with some minor changes.

Keywords: radar technology, multilateration, passive radar, coverage, obstacle, tracking capacity.

1. Introduction

The main task of our project is to offer possible solution not only how to fulfill current needs and requirements of the air space, but also how to solve the problem with the rapid rising level of congestion of the airspace now and in the future. Our solution is based on a new type of technology which has come to civil aviation industry in the past few years: Passive Radar Technology (PSS). In our 5 years long research we were comparing all available and used radar technologies and systems to find one with the best option for future development of the air traffic control, navigation and surveillance. By upgrading the most of currently used surveillance systems there is no possibility to achieve sufficient performance for the future development of aviation industry. The upgrading of currently used radar systems could solve the situation for the short term. PSS technology is a long term solution to increase the capacity with a very high precision, during a very short time for very low costs (in comparison with active radar systems). Our conclusion is that one of the most suitable technologies for this task is the passive surveillance radar technology, previously used only for military operations as the strategic secret weapon but nowadays still more consulted in the sector of civil aviation. Our research is based on findings obtained in cooperation with a company ERA, which is the biggest distributor of passive radar technology and multilateration systems in the world. Other tasks summarized in the topic are to approximate operation and principle of the radiolocation facilities and to describe whole topic of PSS technology also from the historical point of view (development, invention, importance, current status). The article provides a brief overview of alternative solution of airspace coverage by passive radar technique in the territory of Slovak Republic (SR). The result based on the research is a clearly described geographical position of deployment of the PSS radar equipment in the geographical map of SR. This article leads you through information about advantages and disadvantages of using passive surveillance technology and multilatertion in Air traffic control network, as well as technical restrictions. Our conclusions are supported by ERA simulation programs for planning wide area mutilateration (WAM) networks and by consultancy experts. The outcome of this research is a short manual on how to proceed during planning PSS network in different areas and countries with different landscapes and which conditions need to be considered during planning.

2. Principle of work of PSS systems VS active RADARs

PSS system works without the transmitter. All active radars usually use the transmitter providing radars with ability of transmitting signal into the space. The signal in the space is reflected by the objects in the range of the radar only if objects have ability to reflect electromagnetic signal. Such ability is given by construction material of the object. The most of active radar technologies detects this reflected signal by antenna. If object is constructed of material which is not able to reflect electromagnetic signal or shape of the object is specially designed for deflection of this signal, the target will become invisible (undetectable). This is the main disadvantage of active technology which goes in a hand with acquisition and operating costs. PSS technology is able to bring convenient solution and solve these as well as many other problems.

For comparison, the main part of PSS is the system of several receivers. PSS system transmits any electromagnetic signal into the space. Its principle is based only on receiving electromagnetic energy from the space in radar range. Precise position of targets is determined by comparison with all detected signals from all receiving stations of PSS system. This kind of radar is the most common and the most frequently used in application to aviation in military sector. Nevertheless, this technology is still not completely used in civil air traffic. Potential of PSS technology is often

[1] Corresponding author:nikolas.zacik@fpedas.uniza.sk

underestimated by the civil air traffic sector. For air traffic control is nowadays the most common concept of active radar network based on impulse and primary radar technology.
PSS is working on principle of cooperative, independent tracking. PSS system consists of several side antennas located at different places and one central antenna which is used as reference point for all received signals at all antennas. After receiving of signals are all signals evaluated and compared by central antenna. Theoretically is PSS able to detect and track all possible sources of electromagnetic signals. In aviation is commonly used principle of transmitting and receiving message by using secondary radar technology used with cooperation with PSS. In case of this concept is assertion that PSS radar is transmitting any signal, false.
PSS does not transmit any signal, it only receives electromagnetic signals from the space by an antenna system. Despite of passive principle of receiving signals, PSS receiving antennas still need some source of this signal (echo) for tracking of the target. PSS radar is able to detect all kind of radio technical signal from the source. Radio technical signals are all electrical signals from all electronic devices. For this purpose can be sufficient for example transmitter of the radio, television, mobile network, avionic, radar signal or sight technology. The less common signals which is PSS able to detect are signals from household or foreign radars but also a jammer. All these kinds of signals are reflected from all objects in the sky and also on the ground. It creates natural signal which passive radar can process. For data of higher quality are compulsory more antennas in the system for process of evaluating data relative to reference antenna. From differences in the signal of separated antennas is possible to precisely determine position, direction and speed of target in the time.

3. Current situation of using multilateration equipment in SR

There is no multilateration system implemented in Slovak Republic nowadays. Also no PSS is used for civil operations and air traffic control in Slovakia. A few PSS are used for Slovak military air traffic control services. On the other hand, you can find three of these systems used by Air traffic control in Czech Republic. The exact name of this system of PSS radars is Wide Area Multilateration (WAM) system. In Czech Republic, this system is located in the area of cities Brno, Ostrava and Prague. Those three systems are able to cover the whole air space of Czech Republic and also the west part of Slovakia. In Czech Republic, there is also in use one Airport Multilateration (AMLAT) system as part of A-SMGCS in Prague. EUROCNONTROL is nowadays working on the surveillance services supporting the implementation of reduced traffic separation minima, by improving and harmonizing the surveillance infrastructure by using of MLAT systems, their implementation, evaluating, testing, prototyping and legislation for proper use. The main objective of SASS-C EUROCONTROL center for next year research (2017) is to find new tasks for which MLAT and MSPSR could be used, and how MLAT and PSR systems could influence tracking and surveillance in the aviation operations. Another task of the project is to find the best possible existing technology for purposes of MLAT and MSPSR systems to improve their efficiency in comparison with currently used systems for the same purpose.

3.1. Process of implementation of multilateration system for SR

Our research is based on assumption that Slovak and Czech Republic (CR) are very similar areas with similar ground segmentation (see Fig. 1 and 2 below). The most significant problem in CR was to build up WAM network in the area of mountains with sufficient coverage of air space because of the landscape shape which is the most limiting factor. The whole area of CR is 78 866 km² and more than 30% of Czech area is above 500 m above sea level. During WAM system planning in SR we have found the same limiting issue with the landscape. The area of SR is only 49 036 km², but the shape of the landscape is very mountainous (more than 35% of it). This is the main issue to be solved. After taking this into account, the methodology and experiences gathered during building up the Czech PSS system can be also used for building up the Slovak PSS system (mainly in problematical mountain parts) as well as many studies and expert´s opinions. The simulations of ERA company simulator, developed with the aim to design concepts of the architecture, the ERA company expert´s opinions and found historical data have shown that the ideal amount of central stations for the area of Slovak republic is number three. In this configuration and case of cooperation with Czech Air Traffic Control (ŘLP) there is a possibility to achieve in the air space of Slovakia, tracking information with higher precision or less number of used central stations in the network for lowering costs. In the air space of Slovakia in case of lowering costs acquisition during building up the new WAM system, there is an opportunity to reduce number of central stations to one. Disadvantage of the concept with one central station is lower tracking capacity of the system and slower data evaluation as well as congestion of only one central station. In concept of one central antenna all data will be preceded by one station, because this station will be a reference point for all other antennas in the terrain.

3.2. Limiting factors for designed architecture

The number of stations for coverage of Slovak air space dependent mainly on three limiting factors:

- The area which has to be covered
- Ground segmentations and mountains in the country
- The lowest flying level which has to be covered.

Those factors are crucial and restrictive in term of work principle of PSS radar technology. The principle is based on method of multilateraion. For this purpose it is necessary that PSS detects signals from targets direct visibility between the object and the radar. The condition of direct visibility between four antennas and the target in time must always be complied with. In the area of Slovak republic it is necessary to take into account the high mountains which in some areas exceed 2500 m above sea level. The most significant obstacles during planning are in this case are the Tatra Mountains. In case of request to cover lower flight level above ground level, it is necessary to use more central stations and side antennas.

3.3. Design of WAM system for area of SR

This concept of WAM system design for Slovakia is based on collected information about work principles of this system in cooperation with company ERA. They supported this project with materials which contain manual and basic information for design of WAM networks, the same as was used for building up the radar network in Czech Republic. Our concept for Slovakia has been designed for these cities:

Bratislava – we have chosen this area for better coverage in proximity of international Bratislava Airport in the capital of Slovakia from the lowest possible flight level. The main purpose is that there are expected aircraft operations in low altitudes, mainly during take offs and landings. This position will also ensure very precise coverage of whole Danubian Plain and sufficient coverage of western part of Slovakia. The western part of Slovakia situated behind Little Carpathians mountain is perfectly covered by Czech WAM network. In case of sharing the radar data between Czech and Slovak republic will be this part behind obstacle also under control of ATC. The condition of sharing this radar data is not required, as there won´t be flights in such a low altitude. WAM system designed for this area will partly cover the middle part of Slovakia. Our architecture concept for this area is to build eight stations in total. Five of them will be situated near the airport with direct visibility to lower altitude above area of Danubian Plain. Stations around the airport guarantee higher precision mainly in critical area of the airport. Other three antennas will be situated farther from the airport for coverage and better precision of system in other parts outside the airport.

Liptovský Mikuláš – this area was designed to improve the quality of coverage of whole WAM system mainly for mountain area, where the signal can be often shielded by obstacles for stations and antennas from Bratislava and Kosice systems. This central station has to ensure the coverage of northern Slovakia, mainly the area of High and Low Tatras. This system also provides coverage for the area of the third biggest international airport in Slovakia, airport Poprad – Tatry. Our architecture concept for this area is to build seven stations in total. Four of them will be situated near to the airport for the same reason as it is mentioned for WAM system Bratislava in article above. Other three antennas will be situated at the mountain comb of Low Tatras for better range and higher precision of system. The result will be better coverage of whole airspace above airspace of Slovakia, mainly in problematical mountain part. Designed concept will ensure coverage also in the area between hills, although, there is no expectation of any air traffic in such altitude just in case of emergency.

Košice – the main reason for choosing this location is the second biggest international Slovak airport **-** Kosice airport. Other reasons are similar as mentioned above for the area of Bratislava. This central station of WAM system will cover the whole eastern part of Slovakia. Our concept of architecture for this area is total of six stations. Three of them will be situated near to the airport for the same reason as it is mentioned for WAM system Bratislava in article above. Other three antennas will be situated at the mountain called Slovak Ore Mountains for better coverage and higher precision of system in the east part of Slovakia. The position of antennas at the elevated position will ensure direct visibility for whole east area. The result will be the better coverage of whole airspace above the airspace of Slovakia, mainly in problematical mountainous parts.

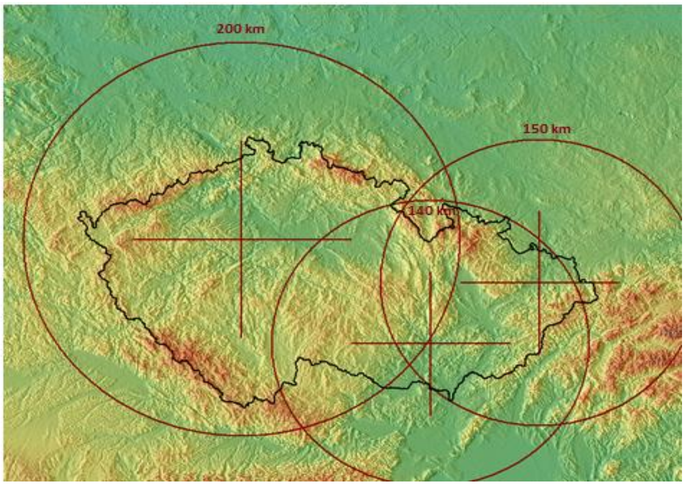

Fig. 1.
Ground segmentation in Czech republic and position of WAM central stations in CR area with partly coverage of SR. Source: ERA company

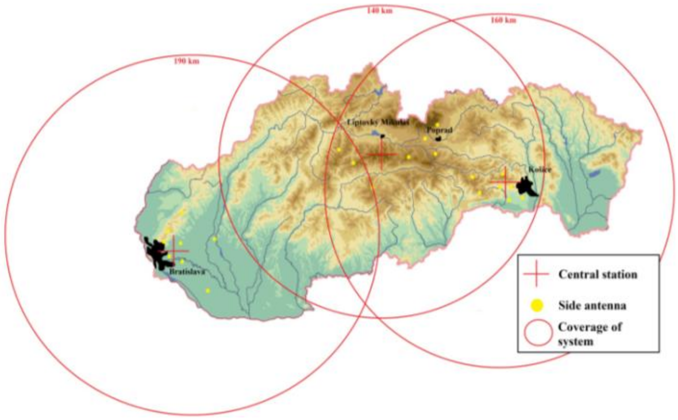

Fig. 2.
Design of WAM system for Slovak republic.
Source: Author Ing. Nikolas Žáčik

The best possible technology with the aim to build up new WAM network is actually the most modern Czech system: P3D-WS at all chosen positions of central stations. This technology removed bugs occurred in the previous versions and also meets all ICAO traffic safety requirements. Previous version P3D-40 was just beta testing version with lower maximal range. All radar centrals in this concept where chosen for the best possible coverage of whole required airspace of Slovak Republic. The concept of three centrals will not ensure the coverage of whole area of Slovakia from the ground, but will ensure the coverage around all international airports in the country as well as the coverage of airspace in the mountain from the altitude where the air traffic can be expected. All side antennas must be placed in the range of 100 km from the central stations. All antennas are communicating between each other and share information about the position of the target. Chosen architecture of WAM network and distance between separated antennas can ensure tracking targets in the range of 350 km in ideal terrain condition. Restrictive factor in maximal possible range is just range of the transponder station, which can effectively works just in range of 100 km. According to the recommendations of Era company, the minimal number is five antennas for one central station. The price of the whole WAM network designed for Slovakia, built up by company ERA is around 3 – 4 million euros. The whole research was supervised by ERA during regular consultations about each point of designing. The concept was developed from theoretical knowledge, based on simulations of ERA company simulator, developed following the design concepts of architecture in all terrain conditions. For better economical overview and advantages of this solution see graph at Fig. 3.

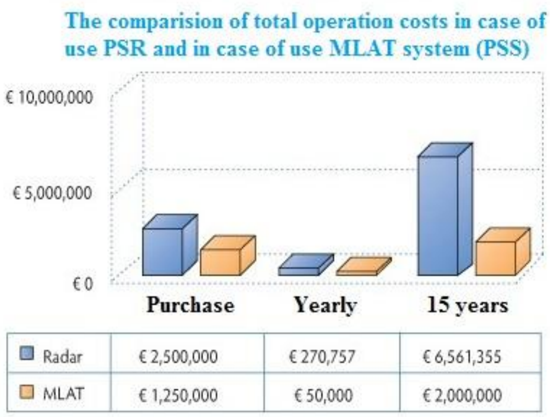

Fig. 3.
The comparison of whole operation costs, in case of using of primary radar (PSR), in comparison with MLAT system (PSS).

4. Conclusion

The final conclusion of the project is to offer an alternative solution on how to build up a radar network and the radar coverage of the overall air space of Slovak Republic's territory. Our concept consists of PSS radar technology, which is provided by Czech company called ERA. This technology is characterized by high level of the precision, reliability and low operating expenses. During designing of WAM system in Slovakia, there were two possible solution concepts of positioning all stations and antennas. The first of them is to build up a network with three independent central stations with several antennas (in case of PSS technology: receivers) for each of them. For this concept is the most important the cooperation between all three stations and also between all antennas. The second possible solution is: to build up just one central station with more antennas in the space, as it is in the first case with 3 central stations, but the costs of this concept will be lower. The Disadvantage of this concept is a lower tracking capacity. After consultation and recommendations of specialists from company ERA, our recommended outcome of new WAM concept for Slovakia is the first solution: to build up a network with 3 separated central stations. The best location for this three stations regarding to terrain in the country are cities: Bratislava, LiptovkýMikuláš and Košice with total number of 21 antennas. The biggest challenge during designing the WAM network in Slovakia were the mountains, especially the area of High Tatras. PSS needs a direct visibility of detected target for correct and smooth operation. In our chosen concept we have achieved the coverage of entire airspace of Slovak Republic with the required range. In addition, the system covers part of the air space of surrounding countries. The range of one system of antennas with central station is approximately 350 km in dependence on ground segmentation. The price of the whole concept of designed WAM system is around 3 – 4 million euros. The exact price depends on the actual number of used antennas and stations. For better overview, one PSR applied for the same purpose, has the price of 3 million euros and its operating costs are 5 or 6 times higher than operating costs of PSS radar. The main advantage of WAM system is the increased level of safety in the air traffic.

Abstract: Range of diverse bird strike effects in air transport put spotlight on this subject in the air traffic industry. Every segment of commercial air transport is interested in this topic and could make a significant contribution because these kinds of events play major role in daily operations disruptions and having safety, economical and organizational influence. Because of its enormous importance in aviation questions are: Is it possible to avoid these events? At what cost? This paper tries to answer what are the costs of bird strike prevention. The first part of paper deals with prevention measures and systems; environment adjustments, trainings, contemporary and technological achievements for reducing bird strike risk. International Bird Strike Committee and ICAO statistical data will complete image of frequency and consequences of these events. Focus will be on comparing benefits of implementing new systems and theirs costs. Finally, based on expected air transport growth investment in control risks cold be comprehended as investment in air traffic safety and progressive cost management..

Keywords: air traffic safety, costs, bird strike prevention, measures.

1. Introduction

Bird strike as ever-present risk in the air traffic became very popular in the past decades and inspired numerous scientists to seek for better solutions to this problem. This challenging issue raises questions regarding air traffic safety, bird strike costs and preventive measures. Modern technical devices are very expensive and some of them won't have same effect on every bird spices therefore detailed analyses are needed before implementing preventive equipment. Bird strike effects on flight depend on various elements like birds mass, density, part of airplane that suffered the impact, airplane material, angel of the bird strike, flight phase, airplane category, engines type, bird spices and etc. Probability of bird strike, as second element of bird strike risk, is being difficult to evaluate and mainly depend on preventive measures that are being used and on biodiversity of certain location. Contemporary methods are used to estimate both severity and bird strike probability.

Bird strike presents common risk in aviation which very often causes incidents particularly in the vicinity of airports. There is, however a lack of systematic approach for real-time bird strike assessment. Some authors (Ning et al., 2013) develop models for the bird strike probability estimation whilst generally estimations are based on the creation of a probabilistic model, inferences about changes to the states of the accident shaping or causal factors can be drawn quantitatively (Ancel, et al., 2015) or on inductive reasoning approach which is employed to develop a prototype hybrid decision support tool whose main objective is to build probabilistic causal models representing the safety risk involved in aviation accidents (Oztekin and Luxhøj, 2010). Some authors (Kermanidis, et al., 2006) developed simulation techniques related to development of suitable material damage models and for simulating the complex failure modes and unfolding mechanisms of quasi-static penetration of simple 'tensor skin' strips, which are representative of the complete leading edge composite structure of the aircraft. Bird strike consequences measured by blade deformation and its modeling is also provided in many experimental tests (Mao et al., 2009 and Salehi et al., 2010).

Majority of authors treat bird strike problems as a part of safety related problems during the aircraft operations, take-offs and landings (Čokorilo et al., 2011; Čokorilo, 2011; Čokorilo et al., 2014), and there is a lack of research dedicated to the cost benefit safety issues (Čokorilo, 2008; Čokorilo et al., 2010; Čavka and Čokorilo, 2012).

Distinctiveness of bird strike costs is its complexity and difficult separation from other costs in air traffic industry. Bird strike could have multiple effects and costs of such event will be calculated as sum of costs of single effects. Beside repair costs, delay/cancelation costs take special place because of theirs possible effect on succeeding flights. No matter what the cause of flight delays are, they are very expensive for aviation industry. Per ITA average unit cost per minute of delay going from 39.4 Euros to 48.6 Euros for the airlines.

Damage and withdrawal costs are determined by extend of damage and MRO company which is servicing the airplane. Extend of damage will mostly depend on size of bird and number of birds that participated in collision. (EASA, 2009) stated that from 1999 to 2008 the majority of birds involved were flocks of large birds (45%) followed by strikes from single large birds (31%). Parts that are the most reported as damaged in bird strikes are the most exposed airplanes parts: engines, wings and windshield.

2. Contemporary bird strike preventive measures

Bird strike preventive measures could be divided into four groups: habitat management, bird movement monitor devices, devices for dispersing birds and chemical aids. These elements will be combined depending on local characteristic. What has to be acknowledged when it comes to bird strike preventive measures is that same measure will not have same effect on two different locations; also effect could be permanent or temporary.

[2] Corresponding author: oljav@sf.bg.ac.rs

2.1. Habitat management

Complex problem like bird strike requires collaboration between different subjects within air transport and outside of it. Three main factors would be airport, air traffic company and municipalities authorities. Multiple elements cooperation is necessary because certain areas will be more attractive to birds then others due to existence of elements that provides food and shelter to the birds. Risky areas will be airports:

- Grassy areas within and outside of airport surface woodland and agricultural fields,
- Near to lakes, seas and globally water rich areas,
- Freshly excavated lend,
- Closeness to sewage or landfill.

It is obvious that effective habitat management requires collaboration with multiple organizations and it is almost impossible for airport to manage this kind of situation on its own. Critical areas that are mention above require careful analysis through few phases. First phase would be detailed observation of airport environmental with accent on topographical, biological, geographical and urban characteristics. Analysis of collected data should be done through second phase which final result should be evaluation of how risky concrete airport area is. Biology experts should be part of the team that conducts this research for analyzing bird behavior patterns. Third phase would suggesting which measures would be most effective and feasible in concrete case in order to reduce bird strike risk. Fourth phase is implementation and evaluation phase. This process needs to be cycle process to ensure that safety standards are met.
Collaboration between different institutions is emphasized during the fourth phase of implementation. For example, analyze of certain airport area may suggest that drying out the field, or landfill relocation is necessary to remove birds from the critical territory. Airport vicinity could be municipality or private property which makes this problem even more complex out of legal and ownership reasons. Habitat management is ever present measure because even if great modifications are not necessary, maintenance of airport area is constant to keep flight zone safe.
This kind of approach to the problem gives the best results because of its long term and comprehensive nature. The most effective way is proactive approach which means infrastructural and urban planning with considering bird strike problem in air transport. In those way costs of landfill relocation, drawing up field and etc. would be avoided because original location would not be accepted as proper because of the problem that may cause. It is clear that with this air transport demand and traffic volume it is not possible to find perfect location every time and to predict bird problem in the future. Therefore, except organization measures others measures need to be applied known as habitat management.
Costs of organizational measures are probably the highest among the bird strike mitigation measures. This type of measures include long term planning, multiple organization collaboration and each organization will have its own costs on this project, complex and expensive terrain modifications which requires engaging trained stuff and proper equipment.

2.2. Bird movement monitor devices

Airport field is wide area and it is difficult to make sure if birds are present in the airport environment and to quantify them. The main purpose of bird radar is to detect small objects movements. Nowadays, different model of radars are being used for tracking birds and other animals. Some of them are multifunctional and beside birds monitoring, they have additional functions, like weather surveillance radar (WSR) that has been used to study bird movements and bat roosts since the late 1950s in the USA. In the early 1990s the WSR-88D (also known as NEXRAD, or NEXt Generation RADar) replaced the older WSR-57, WSR-74S, and WSR-74C radars in the national network (Gauthreaux and Schmidt, 2013). The company DeTect (USA, Florida) developed the ‘Merlin radar system’ specifically for detection and tracking of birds and bats (Figure 1). It is a dual radar system with an S-band HSR and an X-band VSR. The effective range of the VSR is 3 to 5 km and 5 to 7 km for the HSR. Merlin software processes, analyses and records the radar information (Brabant and Jacques, 2010).

Fig. 1.
Different Versions of Merlin Aircraft Birdstrike Avoidance Radars
Source: DeTeact site: <http://www.detect-inc.com/DeTect%20info%20-%20wind/Technical_Data_Sheet_-_MERLIN_Bird_Radars_%20Wind_models_1205.pdf>

Lately Accipiter Avian Radar became very popular for its efficancy and flexibility in use. It can detect and track birds in the vicinity of an airport to within one meter and 2.5 seconds of their actual position. Accipiter has developed an advanced dish that provides unmatched 3-D surveillance. For a multi-transceiver system, an antenna rotates horizontally while a second antenna spins vertically (Watson, 2009).
Is radar going to be used for tracking birds and which model will be chosen for this purpose depend on multiple elements like airport characteristics, level of bird strike risk and funds available. Table 1 shows some of radar model being used for this purpose with their main characteristics and average costs.

Table 1
Different Models of Contemporary Radar Being Used for Bird Tracking

Bird radar model	Range for detecting birds (max)	Characteristics	Price
High-resolution marine surveillance radar	14 km	X-band and S-band version	Not available
Accipiter Avian Radar	20 km	Mobile or fixed version	$200,000 to $1 million per airport
WSR-88D	120 km (75 miles)	Two operational modes	$5,000,000 each unit

2.3. Devices for dispersing birds

Devices for dispersing birds is group of devices that is used for temporary eliminating birds from the critical area, this devices in basic aren't lethal but in certain cases could become deadly. Devices for dispersing birds are guns, laser guns, speakers, repellers that emit ultrasonic waves, scarecrows, trained predators… Sound devices are often used for this purpose, numerous models are in use worldwide with different swapping frequencies and sound that mustn't been disturbing for people. Contemporary measures also include modern repellents which generate ultrasonic waves and with automatically varied frequency. Nowadays mostly solar powered ultrasonic repellents are being used in different areas, from agriculture to air transport. Ultrasonic Bird Repeller Detection belongs to this group of measures, producing an ultrasound of 118dB, on the average will cover a distance of 45.02 m^2 while the 23.98W with an ultrasound of 123dB will cover a distance of 232.26 m^2 when placed on the elevation of 0.78m but when placed on the elevation of 1.86m, their average area coverage will be 175.83 m^2 and 429.53 m^2 (Figure 2). About 5-6 pieces of the 23.98W de vice will be needed to cover a hectare sized field (Ezeonu et al., 2012).

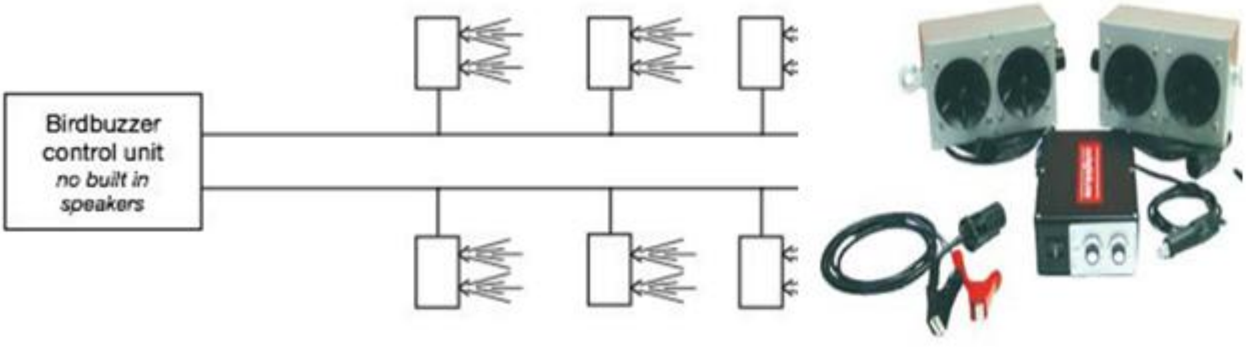

Fig. 2.
Scheme of the Ultrasonic Bird Repeller System and its Elements
Source: <http://www.copybook.com/airport/companies/scaringbirdscom/articles/birdbuzzer-ultrasonic-bird-repeller>

Bird Gard Super Pro Amp is another device used for bird problem mainly in agriculture and at airports which cover a larger territory, even up to 25 acres (Figure 3). It consists of 20 speakers that change the sound every 6 minutes. The device is able to broadcast sound in the range of 125 decibels. The power supply is a solar device is resistant to all weather conditions. Bird Gard Super Pro Amp is mainly used in Australia (Djordjevic, 2012).

Fig. 3.
Bird Gard Super Pro Amp Dispersing Device
Source:< http://www.birdcontrolpro.com/bird_gard_super_pro_amp.htm >

Beside audio, devices with visual effect are also used and their effect varies on bird spices. It has been found that the use of lights at night in high rise buildings can significantly increase the likelihood of nighttime migratory fatalities. Light apparently causes disorientation and attracts birds to structures resulting in impact and death.

Table 1
Different Models of Contemporary Bird Dispersing Devices

Model bird dispersing device	Range for detecting birds (max)	Characteristics	Price
QuadBlaster QB-4	6 500 sq. ft.	Bird repeller designed for indoor and semi-enclosed use	$556.75
Ultrason X	3 600 sq. ft.	Ultrasonic (silent-to-humans) bird repeller designed for outdoor use or in semi-enclosed areas	$670
BroadBand PRO	6 acres	Both sonic & ultrasonic bird repeller, option to include 3 visual scares.	$725
Super QuadBlaster QB-4	6 500 sq. ft.	Ultrasonic pest bird repeller + flashing strobe light is a multi-sensory attack	$670
Bird Gard Super pro Amp	25 acres (10 hectares)	Fully programmable, with adjustments for volume, specific sound combinations, daylight, night, or 24-hour operation.	3300 Euro

2.4. Chemical aids

Chemical aids include all chemical substances which purpose is eliminating birds or food for birds in the airport area. Chemicals are divided in two groups: lethal and non-lethal. Lethal method is very effective but also very controversial due to environmental changes and problem with endangered spices. Chemicals are the cheapest of all previously mentioned measures. Areas with endangered spices must be extra cautious because lethal measures are forbidden. The most common example of using this method is using chemicals to eliminate insects after digging land due to infrastructural changes on the airport. In that way bird will lose food source and inters in airport area.
Non-lethal measures are known as chemical repellents and would evoke two kinds of behavior: first is bird reflective withdrawal or escape due to taste, odor, and irritation; second group of non-lethal measures is causing psychological effect and illness. There is variation on behavior between different spices, for example this method has stronger effect on mammals then on birds, also different birds spices react differently to chemicals. The number of chemical bird repellents is limited, only two are registered for use in the United States: methyl anthranilate and anthraquinone. Methyl anthranilate is a primary repellent that produces an immediate unpleasant sensation that is reflexive and does not have to be learned. As such it is most effective for transient populations of birds Methyl anthranilate has been used with great success at rapidly dispersing. Anthraquinone is a secondary repellent that has a gastronomic effect that is not instantaneous (Clark and Avery, 2013).

3. Costs caused by bird strikes

Because of its complexity estimating of total costs caused by bird strikes in the air transport is very challenging. This kind of costs are far from the bird strike damage costs, that are often interpreted as bird strike costs. According to bird Strike committee USA bird and other wildlife strikes cause more than $650 million in damage to US civil and military aviation annually. In addition, bird strikes put the lives of crew members and passengers at risk — more than 200 people have been killed worldwide as a result of wildlife strikes since 1988 (Nicholson and Reed, 2011). In most cases bird strikes would cause negligible or minor damage to the airplane and flight will continue without disruptions. Sometimes pilots wouldn’t even notice that the bird strike has occurred and strike was discovered at regular airplane technical service.
For creating image of bird strike costs a few questions have to be answered like: How often bird strike happens? What is severity/damage of strike? What are effects on the flight?
<u>How often do bird strikes occur?</u>
Bird strikes are daily events but not all of them have the same effect or cause the same costs. In order to prevent this kind of events predicting them is the key of the problem. Per FAA There have been about 142,000 wildlife strikes with civil aircraft in USA between 1990 and 2013 (about 11,000 strikes at 650 airports in 2013). It needs to be acknowledged that probability of bird strike is not constant during whole flight. Take off/climb and decent/landing are the most endangered flight phases and the great majority of strikes happened during this phases, cursing flights level are too high and bird’s presence is extremely rare therefore bird strike during this phase is unlike to happen but it is not impossible. It is difficult to estimate exact number of strikes because not all of them are reported. Although bird strikes are daily events, accidents with major damage and human loses caused by these events are not that often. On the average, aircraft crashes every eighteen months as a result of a bird strike related incident (Thomas, 1990).
<u>What is severity/damage of strike?</u>
Level of damage caused by bird strike depends on multiple factors like mass of the bird, angle of the impact, matter density, material type and part that suffered the strike. It is clear that exposed parts are the most endangered. Per Boeing three-quarters of bird strikes involve the wing or engines. Engines on the most popular models of large jets, such as the Boeing 737 and the Airbus A320, are not certified to withstand an impact with birds larger than four pounds

(Dukiya and Gahlot, 2013). Repair actions would be taken based on damage degree, if bird strike was not detected during flight servicing will take place during regular technical checks. Engine, as the most vulnerable part of the airplane, beside enormous influence on the safety is giving one more problem - its repair is extremely expensive. Repair of one engine could cost up to few million dollars.

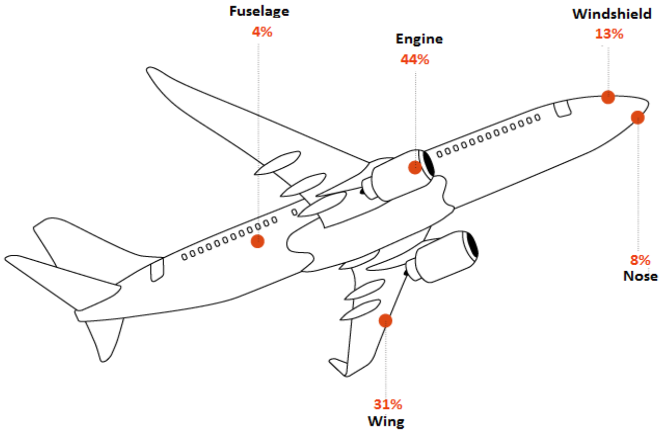

Fig. 4.
Locations of Bird-Strike Damage
Source:(Nicholson and Reed, 2011)

<u>What are effects on the flight?</u>
Bird strike effect on flight greatly depends on part of the airplane that suffered impact. Roughly based on part that suffered impact expected effects are: engine – loss of thrust; windshield – decompression or visibility decreasing; tail – decreasing of stability and maneuverability. As mentioned before not all of the bird strike will have influence on the flight, in most cases flight will be finished without any problems. Expect repair of the damage caused by bird strike and costs of repair material, airplane withdrawal from the traffic and maintenance staff working hours costs there also other bird strike related costs. Collision with bird might require immediate grounding which will lead to flight delay or cancellation and costs that follow this events, also company reputation will be questioned as well as passenger decision to chose same company again.

4. Preventing bird strikes model and costs

Developing model for preventing bird strikes at airports requires analysis of all bird spices that inhabit area and all other biodiversity and biological characteristics of certain area characteristics. Based on analysis airport must be classified into one of following categories:

- Areas with high risk – areas rich with water, insects, migration paths, farms;
- Areas with middle risk – ordinary areas without extra elements that attract birds;
- Areas with low risk – drought and desert areas.

In certain cases area could temporary become very attractive to birds and cases like that require immediate short term actions to remove elements that attract birds which means that presence of temporary activities on the airport must be included in the analysis. The most common case that requires temporary actions is land excavation which is leading to insect’s presence on the surface.
After airport classification, possible modifications should be considered. This modifications could be minor like installing safety nets but in some situations extensive transition actions are required with multiple subjects included. Large modifications are always very expensive and no matter if other measures are applied or not this activities are classified as large investments with high costs.
Except mentioned area adaptations other contemporary technical devices could be used individually or in combination with other devices. Which of this masseurs will be applied depends on first step and analyze of bio-characteristics and bird species features. Basically using dispersing, monitoring and chemical aids is considered as medium investment with medium or low costs but in certain cases modern equipment with multiple functions or combination of few measures could be very expensive and considered as large investment. After terrain modifications and/or technical equipment installation results of implementation must be monitored and evaluated. In case results are unsatisfactory process must be repeated.

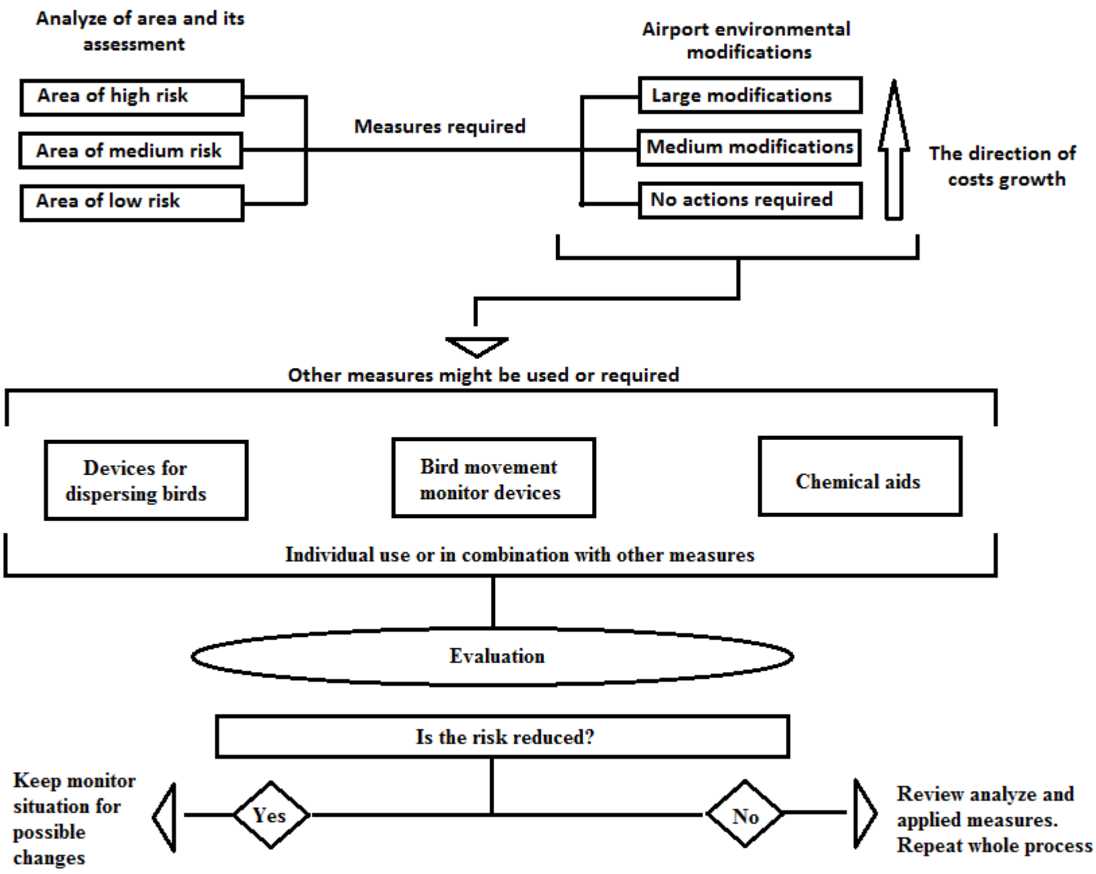

Fig. 5.
Process of Applying Measures for Mitigating Bird Strike Based on Analyze and Airport Assessment

5. Discussion and conclusion

Worldwide expansion both air traffic and birds population is requiring more effective and creative solutions for this problem. Fact that there is no universal solution complicates problem even more. Impact on air traffic safety and enormous costs caused by this problem just confirm that bird strike phenomenon must not be ignored. Complete elimination of this risk is ruled out as an option, this risk is ever present and it is possible only to mitigate it.

In conditions of difficult economy terms and high competition additional bird strike costs are undesirable and companies can't afford expensive repairs, delays, cancelations and airplane withdrawal. Except this costs, there is whole other group of costs which amount is almost impossible to estimate, that costs are costs of lost demand, passengers dissatisfaction, influence on company reputation and modal split. On the other hand managing bird strike risk could be very expensive and overcome airport available budget for this purpose and assistance of other organizations might be needed.

Bird strike management should not be considered as short term project, it is non-stop process. Even if airport is evaluated as bird strike safe area or applied measures gave desired results, that is not point where process ends; constant monitoring and regular reevaluations are required to make sure that there are no new circumstances and that airport maintains safe.

MISMANAGED GO-AROUNDS AND THE NEED TO MITIGATE THEIR OCCURRENCE

Mark Manchanda[1], Ivan Sikora[2]
[1] *Jet Airways Mumbai, India*
[2] *School of Mathematics, Computer Science and Engineering, Tait Building – C110, Northampton Square, London, UK*

Abstract: A missed approach (otherwise known as a go-around) is a part of an instrument approach procedure. It is a maneuver conducted by crew when an instrument approach procedure cannot be completed to a landing.
Main objectives of the study:

- To measure the performance of flight crew performing unexpected go-arounds and the number of errors made. (In a simulated environment)

Sub-objectives of the study:

- To determine whether a co-relation exists between the occurrence of error and the number of missed approaches carried out.
- To evaluate the severity of the errors.

A standardized grading system was used to measure the errors observed, the grading system was adapted from the grading system adopted by the airline industry currently. Constraints were imposed on the crew (weather) to observe the effects of external stress factors on crew performance. 15 sets of crew were tested from Feb 14 to July14 on 3 types of aircraft, B-777, B-787 and A-320 (full flight six axis simulators).

Keywords: go-arounds, mis-managed go-arounds, undesired aircraft state during a missed approach, performance errors.

1. Introduction

A missed approach (otherwise known as a go-around) is a part of an instrument approach procedure, it is a manoeuvre conducted by a pilot, when an instrument approach cannot be completed to a landing. This could be due to a variety of reasons, but the most likely reasons for a missed approach are, ATC (Air Traffic Control) or the meteorological conditions existing at the time of the approach. Flight crew errors are considered to be the primary factor in seventy percent of approach and landing incidents/ accidents. Studies have shown that the errors tend to be of a cognitive nature, among others they tend to be errors of judgment and errors caused due to a loss of situational awareness.

Due to the fact that go-arounds are an uncommon manoeuvre for most pilots, the hypothesis was that errors would increase with every missed approach or go-around that is carried out. A study was conducted to observe the performance of flight crew performing unexpected go-arounds, and determine whether a correlation exists between the occurrence of errors, and the number of missed approaches the crew carried out.

2. Study

A Scenario in a simulated environment was created to allow the pilots to fly from point A to point B.
The fuel provided to the crew was sufficient to carry out a maximum of four approaches.
15 sets of crew (a total of 30 pilots) were used in the study; their age group ranged from 24 years to 60 years and their flying experience ranged from 700 hours to 18,000 hours. All the participants were male and type-rated and current on the aircraft they were being observed on.
All 15 sets of crew attempted two approaches and two go-arounds or missed approaches. 7 sets of crew attempted a third approach and a go-around before a diversion was considered.

2.1. Grading and evaluation of the crew's performance

The sessions were observed and graded according to a set of performance indicators and competencies. A competency is commonly defined as a combination of the knowledge, skills and attitude needed to perform a task according to a prescribed standard. A three-point scale (1= poor performance, 2=acceptable performance, 3=ideal performance) was used for the study.
The data collected was classified according to the following performance markers:

1. (Technical) Automation
2. Procedures
3. Knowledge
4. Communication
5. Decision-making
6. Situation awareness
7. Workload management (Non-technical).

[1] Corresponding author: markmanchanda@gmail.com

While the evaluation of the Technical markers (Automation, Procedures and Knowledge) is relatively straightforward, the non-technical markers present more of a challenge. In order to remove any bias and subjectivity on the part of the observer, the grading criteria is based on the NOTECHS system created by the European Air and Space Agency (EASA, formerly known as JAA), and further explained by Flin 2003, pp. 95 – 117):

"Five operational principles were established to ensure that each crewmember receives as fair and as objective an assessment as possible with the NOTECHS system.

1. Only observable behaviour is to be assessed - The evaluation must exclude reference to a crewmember's personality or emotional attitude and should be based only on observable behaviour. Behavioural markers were designed to support an objective judgement.

2. Need for technical consequence - For a pilot's non-technical skills to be rated as unacceptable, flight safety must be actually (or potentially) compromised. This requires a related objective technical consequence."

2.2. Analysis of simulator observations

The observations can be looked at in two ways, the occurrence of errors per crew, and the number of actual errors.

Occurrence of errors: while some crew made a few errors on the 1st attempt - 3 out of 15 made errors (20%) the other 12 were error free, the errors increased as the crew undertook more approaches. The errors increased to 8 sets of crew out of 15 on the 2nd approach (53%), and on the 3rd attempt every single set of crew that attempted an approach made an error 7 sets of crew out of 7 (100%). It is important to note here that two crews who were totally error-free **did not** attempt the third approach.

Number of errors: for the number of errors the author looked at the data set as a whole to gauge the total number of errors possible. Given that there were 15 sets of crew and they were graded according to 7 markers, this allowed for a possibility of a total 105 errors. On the 1st attempt by all the crew a total of 4 errors were observed out of a total of 105 possible errors (3.8%), on the 2nd attempt a total of 16 errors were observed out of a total of 105 possible errors (15.23%). On the 3rd attempt however only 7 sets of crew attempted approaches and subsequent missed approaches so the maximum amounts of possible errors were 49, out of which a total of 15 errors were observed (30.6%)

Occurrence of error rating 1 (most severe error)

The author then looked at where errors occurred. It was found that which each approach as the stress of making a landing increased, the crew was committing more errors, with the majority being in decision making and situation awareness. For example, attempting to accomplish a landing with the tailwind component greater than 15kts, or actually going below the decision height and making a landing. On the first approach no errors on decision-making were observed.

The following charts were created from the data collected.

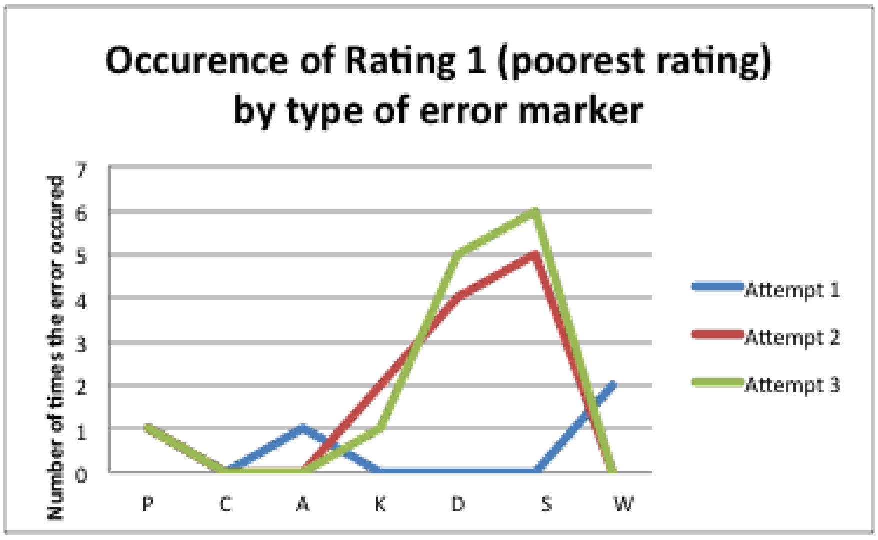

Fig. 1.
Occurrence of rating 1 (poorest rating) by type of error marker

This can be seen more clearly when we look at the charts for Rating 1 (Fig. 2) and Rating 3 (Fig. 3) separately:

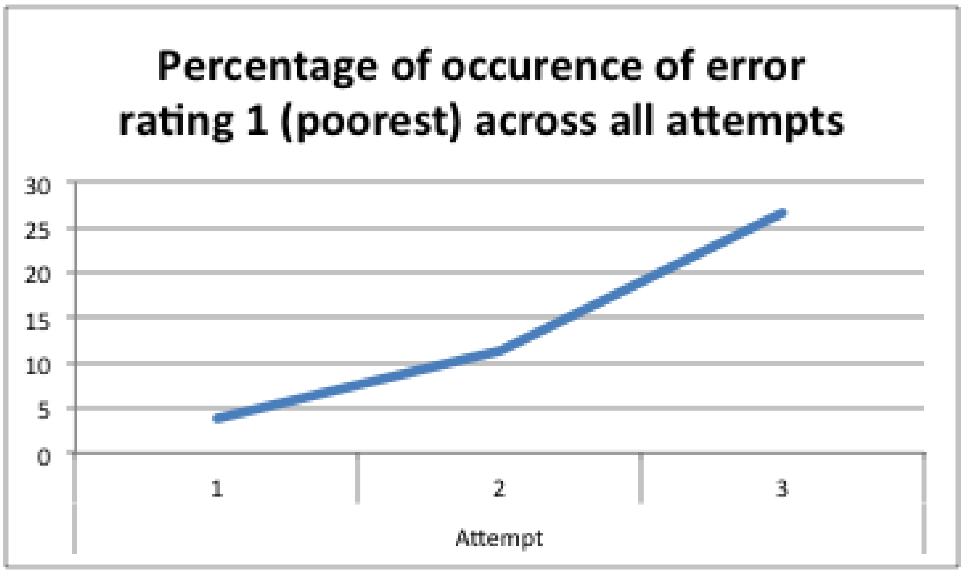

Fig. 2.
Percentage of occurrence of error rating 1 (poorest) across all attempts

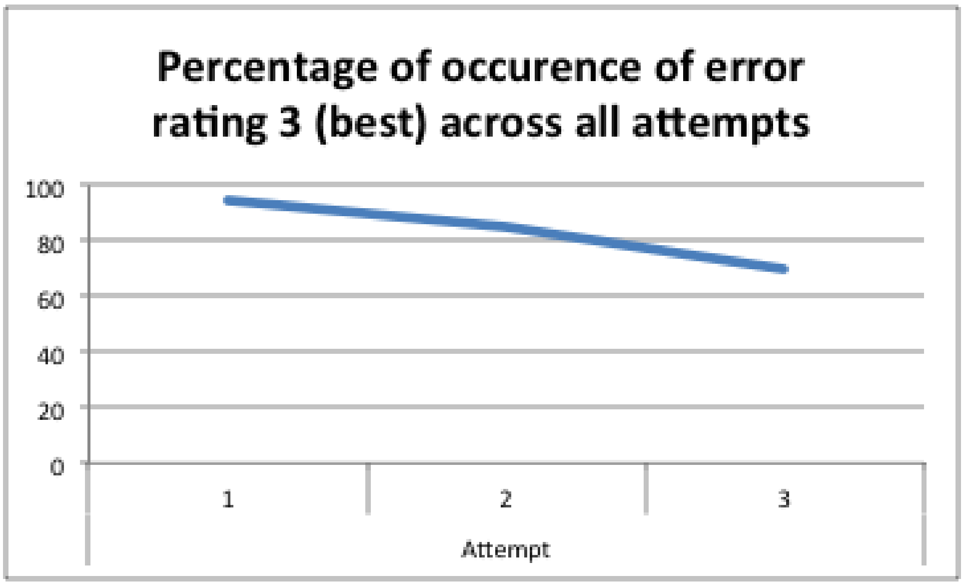

Fig. 3.
Percentage of occurrence of error rating 3 (best) across all attempts

3. Implications of mismanaged go-arounds in the aviation industry

This incident above shows the threat that mismanaged go-arounds can pose to flight safety. A degradation of situational awareness on the part of the crew almost led to an undesired aircraft state. As the research conducted demonstrates the errors increased with each subsequent go-around. As noted in the result section not only did the incident of errors increase on each subsequent go-arounds but the number of errors also showed a steep increase. Given the published statistic (Weigmann and Shappell 2003) that 70 to 80% of all aviation accidents are caused by human error it is therefore of vital importance to identify where these errors occur and take steps to reduce the possibility of their occurrence.
The hypothesis of this study was that human errors would increase with every missed approach or go-around that is carried out. This study clearly shows that mismanaged go-arounds are a potential source of error.

Objective	**Outcome**
To measure the performance of flight crew performing unexpected go-arounds and the number of errors made	It was noted that errors did occur when flight crews had to perform a go around. These increased with each subsequent attempt. On the first attempt 20% of the flight crews made errors in at least one performance marker. This increased to 53% on the second attempt and 100%

	(in at least one performance marker) on the third attempt.
To determine whether a correlation exists between the occurrence of errors and the number of missed approaches the crew carries out	There was a noted degradation in performance with each unexpected go-around. In addition to the occurrence of errors increasing, the number of these errors also increased. On the 1st attempt by all the crew a total of 4 errors were observed out of a total of 105 possible errors(3.8%), on the 2nd attempt a total of 16 errors were observed out of a total of 105 possible errors (15.23%). On the 3rd attempt however only 7 sets of crew attempted approaches and subsequent missed approaches so the maximum amounts of possible errors were 49, out of which a total of 15 errors were observed (30.6%).

4. Conclusion

Failing to abandon a risky approach when necessary can be disastrous, but several times in recent years go-arounds, formerly considered a simple maneuver, have themselves ended in disaster. Go-arounds occur between one and three times every 1000 flights (Flight International 29th July 2014). This gives rise to a very interesting question: is it safer to continue and land off an unstabilized approach or carry out a go-around? According to the Flight Safety Foundation 3.5-4% of all approaches are deemed to be unstable[2].

The results show strong and unambiguous support for the hypothesis, allowing the author to conclude that even though the research was single blinded if a more elaborate double-blinded process could be undertaken, the results would be similar. The results clearly show that a deficiency lies in the cognitive element of human information processing and not with knowledge, procedures or any of the technical elements. Sadly the current training and recurrent training programme's in force at a majority of airlines worldwide do not give the airlines the flexibility to prioritize issues that arise from time to time. Dated regulatory requirements sadly dictate current training programme. Endorsement training and recurrent training syllabi concentrate on missed approaches with an engine failure but do not practice or recommend the practice of full power two engine missed approaches, which is where the mis-management arises. In fact the pilots surveyed during the BEA study felt they were more than adequately trained for single engine missed approaches but not for those when all engines are operating. To quote flight international " Go-arounds are frequently infrequent and although they are an unexceptional procedure, that does not mean for pilots they are an everyday occurrence"

Until such time as EBT or another alternate form of training allows airlines the flexibility to adjust their training syllabus, it is the strong recommendation of the author that airline seriously consider a limit on the amount of missed approaches that a flight crew can accomplish and only attempt a 2nd or 3rd approach if the weather improves substantially.

INFLUENCE OF PERFORMANCE DEGRADATION ON AIRCRAFT SAFETY

Đorđe Pantović[1], Olja Čokorilo[2]
[1,2] University of Belgrade, Faculty for Transport and Traffic Engineering, Vojvode Stepe 305, 11000 Belgrade, Serbia

Abstract: The aim of this paper is to determine the influence of aircraft performance degradation on necessary take-off field length. In this paper, the methodology of determination of required field length for aircraft take-off is presented. In order to determine the influence of aircraft performance degradation on required take-off field length, it is necessary to calculate the approximated values of aircraft lift and drag coefficients. After calculating aircraft lift and drag coefficient values, an equation of required lift-off field length is implemented. In order to solve the above mentioned equation, it is necessary to make some assumptions of constant values in equation such as air density, runway friction, aircraft mass and the runway length required to lift-off. These values can be measured in exploitation of an aircraft in real conditions and recalculate the runway length required. During model evaluation, authors concluded that required field length for lift-off and take-off is increasing with aircraft drag increase which has a great influence on air traffic safety, especially in a situation where aircraft experiences engine failure during takeoff. In order to maintain high level of air traffic safety, authors proposed several actions that need to be implemented in aircraft exploitation process. The influence of the aircraft performance degradation on required take-off field length has never been analyzed before, although there is a possibility to implement this particular methodology in the aviation industry in a practical manner.

Keywords: aircraft, safety, performance, drag, performance degradation.

1. Introduction

In aviation, the most critical phases of flight in terms of aircraft safety are considered to be take - off and landing phases (Čavka et al., 2014; Čokorilo et al., 2010; Čokorilo et al., 2011; Čokorilo et al., 2014). Safety reports from The European Aviation Safety Agency (EASA) indicate that about 44% of aircraft accidents occur during runway operations, ground operations, approach and initial climb and as a consequence of controlled flight into terrain (EASA, 2015). For this reason, it is necessary to pay special attention during the process of analysing and calculating aircraft performance parameters in these critical phases of flight. This issue is of particular interest because, in practice, the degradation of the performance characteristics of an aircraft during exploitation process is often neglected and overlooked. During research process, authors have found that previous researches on this particular topic were primary focused on performance degradation of aircraft and its elements related to aircraft reliability and effectiveness and not as an issue related to aircraft exploitation quality or aircraft safety during flight. The aim of this paper is to analyse the influence of aircraft performance degradation of aircraft safety during take-off operations. Given the fact that the degradation of aircraft performance mainly reflects in an increase in aircraft drag, it is necessary to perform a detail analysis of influence of aircraft drag increase on required take-off field length and the influence of aircraft drag increase on characteristic values of flight parameters at this flight phase such as v_1 decision speed, aircraft pitch rotation speed v_r, and the take-off safety speed v_2 (Cavcar et al., 2004). It is particularly interesting to analyse the issues related to the required accelerate and stop distance. It is necessary to perform a detailed analysis of aircraft performance in the event of one engine failure during take-off and initial climb (Ford, 1998).
In the second chapter of this paper, the mathematical model of aircraft performance degradation influence on required take-off field length is presented. In the first and second section of this chapter, methodology of gathering data of interest is presented. By usage of airliners intern documents such as Flight Crew Operating Manual (FCOM), authors calculated necessary data for proper model formulation. Aircraft performance data necessary for the formulation of the mathematical model of aircraft drag increase influence on required take-off field length were gathered from FCOM published by national flag carrier Air Serbia, for aircraft Airbus A319/320 which operates in Air Serbia fleet (Air Serbia, 2011). By usage of aircraft performance take-off charts (RTOW), authors determined the mathematical function of required take-off field length increase with the increase of aircraft drag. In this particular case, the model has been made for the case of take-off from Paris Orly airport from runway 08. In order to make required take-off runway length estimations for certain airport it is necessary to use the data from valid RTOW chart of airport for which the estimation is made.
In the third section of the second chapter, the model results are presented and discussed. During model evaluation, the authors noticed several potential hazardous situations which can occur as a consequence of aircraft drag increase which are also discussed in this chapter. At end of this chapter, authors proposed several actions that need to be implemented in order to decrease the negative influence of aircraft performance degradation on aircraft safety. In the final chapter of this paper, concluding remarks are presented.

2. The model

The method of estimating the influence of aircraft performance degradation on required take-off field length is presented for an aircraft Airbus A319-100, but can be determined for every other aircraft. In order to define the model

[2] Corresponding author: oljav@sf.bg.ac.rs

with top precision possible, it is necessary to define the gathering process of input data. The aircraft take-off performance data is published by aircraft manufacturer in FCOM in take-off section. The first step in model formulation is the estimation of aircraft lift and drag coefficients. In this case, the lift and drag coefficients are estimated for entire aircraft and not for its components separately.

2.1. Aircraft lift coefficient calculation

Aircraft lift coefficient calculation is a complex problem because the forces acting on aircraft are variable which leads to a conclusion that lift equation should be a differential equation. However, in this particular case, problem can be solved without usage of differential equations. Since aircraft lift coefficient describes aircraft aerodynamic characteristics and its position in airflow, it is possible to determine a moment of time during aircraft take-off process when it is possible to calculate aircraft lift coefficient value. The problem can be solved by usage of this methodology because the lift coefficient values are of no interest during aircraft ground roll. The first equation which can be used for aircraft lift coefficient calculation is the basic equation for calculation of lift coefficient of an aircraft with constant speed and height in certain flight level, as it is shown in (eq.1),

$$mg = \frac{1}{2}\rho v^2 S C_l \tag{1}$$

Where m is aircraft mass, g is Earth's gravity, ρ is outside air density, v is aircraft velocity, S is effective wing surface and C_l is lift coefficient. Equation (1) obviously cannot be used in this form for several reasons. First reason is that aircraft accelerates during take - off therefore speed is not a constant value. Second reason is that effective aircraft wing surface (S) and aircraft lift coefficient (C_l) are not same for different flaps and slats positions and third, the outside air density varies for different air temperature and pressure values. In order to calculate aircraft lift coefficient by using the equation (1) it is necessary to apply several corrections. Outside air density can be approximated with usage of outside air temperature (*OAT*) and pressure which both can be measured. Aircraft take-off parameters are published by aircraft manufacturer in RTOW charts for different values of *OAT* (Fig. 1.).

Fig. 1.
Paris Orly Airport RTOW Chart
Source: (AirSerbia)

Airport RTOW charts are calculated for every airport where certain airliner operates. It consists of general data such as aircraft engine type, airport elevation, take-off runway, runway surface condition and environmental data. This general data define which chart shall be used in take-off performance calculation. Relevant data used in model formulation is Operational Take-Off Mass (*OTOM*), decision speed (v_1) rotation speed (v_r) and safety speed (v_2). This relevant data is calculated and presented for different *OAT* values, flaps configurations and wind. For example, For *OAT* equals to 13°C, flaps configuration 2 and wind 0kt, *OTOM* equals to 81.4t, v_1 equals to 156kt, v_r equals to 156kt and v_2 equals to 161kt. Outside air density can be calculated from International Standard Atmosphere (ISA) tables (REF).
Effective wing surface and lift coefficient influence can be approximated with usage of sets of data points for different flaps configuration (Table 1, Fig.1).

Table 1
Airbus A319-100 flaps and slats configurations

Configuration	Flaps (°)	Slats(°)
0	**0**	0
1+F	10	18
2	15	22
3	20	22

Source: (A318/319/320/32 FCOM, AirSerbia)

In order to estimate the aircraft lift coefficient value, it is necessary to formulate the first moment of time during aircraft take-off roll where lift coefficient can be calculated. This methodology provides certain speed value which can be used in equation (1) in order to produce approximated lift coefficient value. During aircraft take-off acceleration, lift force grows, and in moment when aircraft lifts off, lift force is equal to aircraft weight. This moment is called lift-off moment and aircraft speed in this particular moment is named lift-off speed (v_{loff}). Lift-off speed can be approximated to be 10% greater than rotate speed. After defining input data, equation (1) can be formulated for aircraft take-off condition (eq. 2).

$$OTOM \cdot g = \frac{1}{2}\rho {v_{loff}}^2 S C_l \tag{2}$$

Utilization of equation (2), produces the aircraft lift coefficient values for different flaps settings. Since aircraft lift coefficient presents the measure of aerodynamic characteristics of an aircraft it can be determined for each take-off flaps configuration separately. For purposes of this model, we assume that take off runway is runway 08 on Paris Orly airport, ISA conditions, no wind and greatest aircraft mass possible which is *OTOM*. Since airport elevation equals to 277ft, in ISA conditions, *OAT* equals to 14°C. Outside air density can be calculated from ISA tables for determined *OAT*. In order to calculate *OTOM* and v speeds for different flaps configurations, it is necessary to interpolate between values for *OAT* equals to 13°C and *OAT* equals to 23°C, because there are no data for *OAT* equals 14°C in RTOW chart (Fig.1). Interpolated values of *OTOM*, v_1, v_r and v_2 are calculated and presented (Table 2).

Table 2
Interpolated values of OTOM, v_1, v_r and v_2 for different flaps configurations

Configuration	***OTOM*(t)**	**v_1 (kt)**	**v_r (kt)**	**v_2 (kt)**
1+F	81.13	158.7	158.7	159.8
2	81.34	155.8	155.8	160.8
3	81.55	158.7	158.7	160.8

After calculating and gathering all relevant data, lift coefficient values can be calculated by usage of equation (2). For *OAT* equals to 14°C, outside air density in ISA conditions equal to 1.212kg/m^3, v_{loff} is, as previously stated, equal to 1.1 times v_r which are already calculated (Table 2) and aircraft effective wing surface equals to 122.8m^2 (Airbus, 2015). For previously stated condition, lift coefficients equal to 1.319166 for flaps configuration 1+F, 1.372275 for flaps configuration 2 and 1.325995 for flaps configuration 3. High values of aircraft lift coefficient can be explained through great angle of attack during lift off and extended flaps and slats (Fillipone, 2008).

2.2. Aircraft drag coefficient calculation

Aircraft drag estimation is even more complex than lift estimation. Aircraft manufacturers rarely publish precise data regarded to engine power settings and aircraft drag. In this part of paper, the unique take off model, which can be used for different flaps /throttle setting in take-off performance calculation, is presented. The aerodynamic and engine data for this model is imported from FCOM published by aircraft manufacturer. In order to estimate aircraft drag coefficient, it is necessary do apply certain assumptions. Centre of gravity position does not have influence on drag value obtained from low speed polar. The aircraft take off mass change is small. We assume that aircraft mass during take-off is constant. Environmental conditions are *ISA* conditions, aircraft takes off from dry runway, no wind and no runway slope. Aircraft drag coefficient can be calculated from the distance required for acceleration during take-off equation. Distance to accelerate to rotate speed from *v=0* is calculated by utilization of eq. 3 (Mirosavljević et al., 2010).

$$1 = \frac{1}{2g}\int_0^{v_{rot}} \frac{dv}{\frac{T_n}{G} - \mu - \left(\frac{v}{v_{rot}}\right)^2\left(\frac{C_d}{C_l} - \mu\right)} \tag{3}$$

By usage of Wolfram Mathematica® 7.0 software, a feasible solution of eq. 3 is obtained by eq. 4.

$$L1 = \frac{1}{g}\left(-\frac{-C_l \cdot {v_{rot}}^2 \cdot log\left[C_; \cdot |G \cdot \mu - T_n| \cdot {v_{rot}}^2\right] + C_l \cdot {v_{rot}}^2 \cdot log\left[|C_l \cdot G - C_l \cdot T_n| \cdot {v_{rot}}^2\right]}{2(C_d - C_l\mu)}\right) \tag{4}$$

In eq. 4, *G* is aircraft weight, T_n is take-off net thrust for both engines in kN, μ is runway friction coefficient, C_d is aircraft drag coefficient and *L1* is required take-off distance. The (eq. 4) can be utilized for aircraft drag coefficient calculation because there is no significant difference in aircraft position in airflow from the point of rotation to the point of aircraft lift-off. Engines net thrust in this particular case is assumed to be maximum take-off thrust of an engine type IAE V2500-A1, which can be read from RTOW chart (Fig.1.) and Engine Performance Section in FCOM. Since there are two unknown variables in equation (4), which are aircraft drag coefficient C_d and distance required for aircraft to accelerate from v=o to v_r, it is necessary to assume the distance necessary for acceleration.

For the purposes of this model, it is assumed that aircraft needs 70% of Take-Off Runway Available (TORA) to achieve v_r speed. This data can easily be measured in exploitation and the model can be easily adjusted for the certain aircraft of interest for analysis. Runway friction coefficient can also be measured on the take-off runway. Therefore, with gathering input data process finished, it is possible to calculate aircraft drag coefficients for different flaps settings.

For the purpose of model validation, aircraft drag coefficients have been calculated for ISA conditions, dry runway and runway friction coefficient equal to 0.02, *OTOM*, *OAT* equal to 14°C, Maximum Net Take-Off thrust equal to 102480N per engine and distance to accelerate to rotate speed from $v=0$ equal to 2324m which is 70% of available runway 08 length on Paris Orly airport. For previously stated conditions calculated aircraft drag coefficient for flaps configuration 1+F equals to 0.231351, for flaps configuration 2 equals to 0.249037 and for flaps configuration 3 equals to 0.229921. Estimated drag values for different flaps configuration are greater than usual values due to extended flaps.

2.3. Aircraft performance degradation influence analysis

In this section of the paper, the analysis of aircraft drag increase on required take-off field length is presented. After determination of aircraft lift and drag coefficients, it is possible to perform aircraft drag variation in order to estimate its influence on distance required for aircraft acceleration from v equals to 0 to v_r. The aircraft drag values are increased to 15% total with increment 0.5%. For different flaps configuration, the influence of aircraft drag increase on required take-off field length is determined by calculating each point separately (4). After calculating sets of data points it is possible to graphically present the results (Fig.2.).

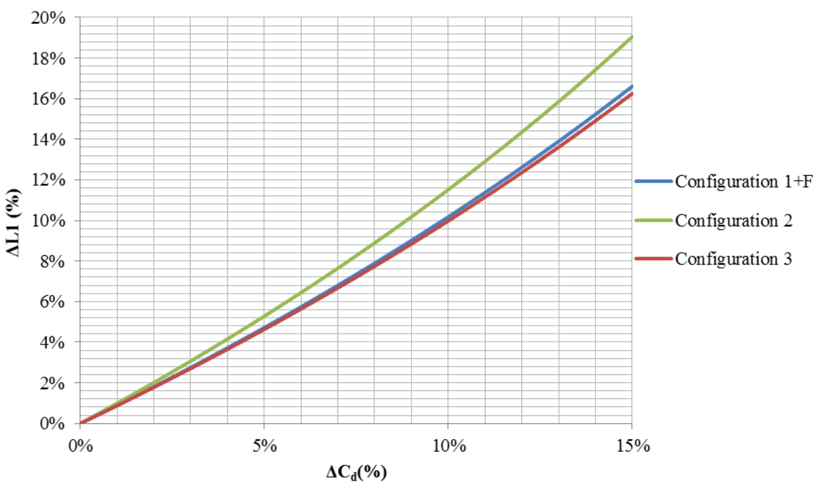

Fig. 2.
Deviation of required runway length for achieving v_r ($\Delta L1$) with aircraft drag increase (ΔC_d)

After determining sets of data points it is possible to determine the fitting functions for each flaps configuration by usage Microsoft Excel® software. The fitting functions are quadratic equations with determination coefficients values close to 1. The fitting function of aircraft drag increase influence on required runway distance to achieve v_r for flaps configuration 1+F is named $L1_{corr1+F}$ (5), for flaps configuration 2 is named $L1_{corr2}$ (6) and for flaps configuration 3 is named $L1_{corr3}$ (7).

$$L1_{corr\ 1+F} = 3955.1 \cdot \Delta C_x^{\ 2} + 1965.8 \cdot \Delta C_x + 2325 \tag{5}$$

$$L1_{corr\ 2} = 5207.9 \cdot \Delta C_x^{\ 2} + 2149.7 \cdot \Delta C_x + 2325.5 \tag{6}$$

$$L1_{corr\ 3} = 3787.4 \cdot \Delta C_x^{\ 2} + 1397 \cdot \Delta C_x + 2325 \tag{7}$$

Previously stated equations indicate that required take-off runway length increases with aircraft drag increase. This practically means that aircraft needs greater runway length for take-off than calculated by usage of FCOM which leads to a conclusion that safety of an aircraft and its passengers can be compromised if aircraft performance degradation is not analysed. Required take-off runway length increase has direct influence on initial climb gradient which leads to a conclusion that there is probability that aircraft won't be able to achieve minimum obstacle clearance altitude. On the other hand, greater aerodynamic drag value leads to less quantity of available engine thrust which leads to decreased

airspeed values. Decreased airspeed values have direct influence on aircrafts safety, especially in cases when airspeed is close to stall speed.
Since rotate speed v_r and decision speed v_1 are in most cases equal, this particular analysis can be implemented in situations when one engine fails during take-off process. Aircraft drag increase, increases the runway length necessary to achieve decision speed. This leads to a conclusion that aircraft has less runway length available to perform full stop after one engine failure. Even if pilot performs full braking, it is questionable that aircraft can perform full stop before the end of runway.
In a situation when pilot decides to continue take-off after one engine failure, initial climb gradient with one engine inoperative has less value than climb gradient with all engines operative which leads to a conclusion that there is probability that aircraft won’t be able to achieve minimum obstacle clearance altitude during initial climb.
Previously stated facts indicate that aircrafts safety will be compromised if aircrafts performance degradation exceeds certain calculated limits. For this reason, in order to maintain aircraft safety on a satisfactory level, it is necessary to perform detail analysis of performance degradation for each aircraft in fleet with data gathered from real aircraft flights. This methodology allows operator to calculate real aircraft performance and prevent aircraft safety endangerment.

3. Conclusion

Aircraft performance degradation has negative influence on aircraft exploitation quality in several different manners. In order to overcome additional drag, which is consequence of ageing aircraft and its exploitation, it is necessary to generate additional thrust which reduces excess thrust margin. In flight regimes where engine runs close to its full potential, aircraft performance degradation can lead to loss of airspeed due to lack of excess thrust. Additional thrust generation leads to increased fuel consumption which leads to greater exploitation costs. Additional fuel necessary to overcome aircraft performance degradation issue, reduces maximum payload which has direct influence on income.
Aircraft performance degradation has direct impact on aircraft safety. Increased drag increases required runway take-off length and decreases climb gradients of an aircraft in cases of all engines operative and one engine inoperative. Increased drag increases fuel consumption which is also a safety issue.
Beside safety issues caused by aircraft performance degradation, it is necessary to mention operational issues caused by performance degradation. Operational issues caused by negative influence of aircraft performance degradation are technical delays, return to ramp or aborted take-off which can lead to operational disruption of flights schedule and loss of income in case of cancelled flights.
The impact of aircraft performance degradation on the safety of aircraft operations can be reduced by creating adequate procedures, by performing revisions of flight operations manual on the basis of data collected from practice, adequate training of staff which handle the aircraft, equipment and other systems that are in contact with the aircraft as well as staff training for emergency cases. Constant monitoring of the degradation of aircraft performance helps optimize the maintenance plan of an aircraft, maintaining a high level of aircraft safety, and to perform optimization of flight parameters in order to reduce the aircraft exploitation costs.

ESTIMATED COST-BENEFIT ANALYSIS OF RUNWAY ACCIDENT SEVERITY REDUCTION BASED ON ACTUAL EMAS ARRESTMENTS

Rob van Eekeren[1]
[1] Safe-Runway GmbH, Germany

Abstract: Is next to preventing a runway excursion also mitigating the outcome / severity of a runway excursion a cost effective method in reducing the risk? In the automotive industry has increasing the survivability of an accident become a voluntarily industry standard. Survivability enhancements in aircraft are due to weight and emission limitations very limited. However infrastructural mitigations at aerodromes are possible in line with current ICAO and the competent authorities guidelines. Are the investments in runway infrastructures that increase survivability enhancements, justified when related to potential safety benefits and the associated costs? Some aerodromes believe not and have non-standard runway safety area's. This paper analysis runway overrun accidents into a non-standard runway end safety area, however equipped with engineered material arresting system as mitigation. These runway-overrun accidents are analyzed and accidents costs are estimated. The accident costs consist of damage; operational; opportunity; injuries and the indirect safety costs. For human injuries a method is defined based on the costs of the accident injury score. At the same time are the costs estimated in the hypothetical case that EMAS would not have been installed. The difference, compensated for the worldwide installation costs, provides a cost-benefit indication. The total net savings are estimated at one Billion $. The law of diminishing returns poses a financial limit to limit to future runway overrun preventions. It is concluded that mitigating certain runways by bringing a non-standard runway end safety area either up to standard or mitigate it to an equivalent level of safety, is a cost effective method to reduce the risk for human life's, injuries, property and equipment.

Keywords: runway safety, RESA, EMAS, cost-benefit, ALARP overruns, excursions.

1. Introduction

An Airbus A340-300, landed in severe thunderstorm conditions in heavy rain, touching down approximately halfway down the non-grooved runway at Toronto Pearson International Airport, Ontario, Canada. The aircraft did not stop before the runway end and overran into a ravine. The runway did not contain a standard runway safety end (RESA). 12 out of the 309 people on board received injuries. Impact forces and a post-impact fire destroyed the aircraft.
What are the accidents costs now, what would these have been with a full RESA and would that have justified an investment in a RESA or equivalent?

The EAPPRE aims at preventing runway excursions, however with close to 50% of aviation accidents and fatalities occurring on or near the airport a certain rest risk will always remain (BOEING Statistical summary). Figures over the period 2011-2014 indicate no significant drop as compared to the 1995-2008 (NLR-ATSI; FSF). Aviation traditionally has always successfully focused on prevention, due to the non-survivability aspect of airborne accidents. However ground based accidents could in principle also be survivable with the right severity reducing mitigations.
The costs of preventing an accident (COI) rise exponentially when the chance becomes extremely low (p^{acc}). The costs of Investment (COI) rise exponentially, while gains from investment (GFI) remain the same. Thus the return on investment (ROI) of only preventing measures will become negative with a decrease of the accident probability (law of diminishing returns). Therefore is it to be expected that the costs associated with prevention will at a moment pose financial limits to further increasing safety. Could reduce the severity of a ground based aviation accident be cost effective and thus provide an additional method in reducing the risk?

$$\left\{\frac{GFI}{\lim_{\text{pacc}).\ 0}} => \infty COI\right\} \text{ and } \frac{(GFI-COI)}{COI} = ROI \tag{1}$$

The costs related to a runway excursion risk could, when combined with a probability calculation, provide a solid motivation if investing in a RESA (or equivalent) is cost effective. This additional approach could potentially save human lives, reduce the number and level of injuries, save aircraft and reduce the damage to equipment and property.

2. Runway overrun risk mitigation by RESA

Risk is a function of Probability and Severity of an occurrence. Combining these two separate elements provides an indication of risk.

Risk = f{Probability|Severity}

Safety Management Systems are capable of identifying and mitigating the possibility of an occurrence. ICAO doc 9859 describes the management flow, including identifying the hazard, the consequences and as a result the risk. The result of an overrun is mitigated by a RESA. The Runway End Safety Area (RESA) intends to reduce the risk of damage to an

[1] Corresponding author: robvaneekeren@safe-runway.com

aeroplane undershooting or overrunning the runway. It provides that protection up to 90 meters and as far as practicable up to 240 meter (code 3 or 4) or 120 meter (code 1 or 2) additional to the runway strip length of 60 meter at the runway end (ICAO annex 14 § 3.4-3.5). That provides thus a minimum length of 150 meters and as far as practicable 300 meters for aircraft undershooting or overrunning the runway. Research by the FAA (1975-1987) indicates that a 1000 feet RSA is expected to stop 91% of overrunning aircraft (Dry RESA).

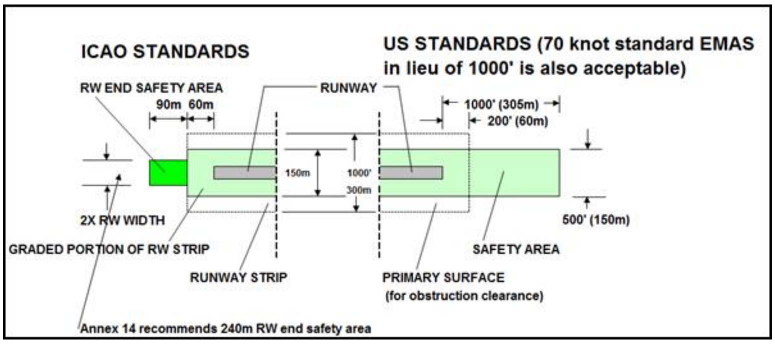

Fig. 1.
RESA & EMAS
Source: Zodiac Arresting systems

An FAA tested and approved method to compensate inadequate Runway Safety Area's (RSA) is Engineered Material Arresting system (EMAS). In order to provide an equivalent level of safety for those runways not having a full RSA, provides Engineered Material Arresting Systems (EMAS) a unique form of overrun protection for airports. Placed at the end of a runway in the form of a bed that crushes under the weight of an aircraft, the EMAS decelerates the aircraft and brings it to a safe stop within the overrun area (70 knots entry design speed limit of most critical aircraft). It intends to provide an equivalent level of safety compared to a full RESA. EMAS is installed on over 100 runways world-wide and has successfully and safely stopped aircraft. Arrestment's show very little or no minor damage to the arrested aircraft and no injured people or fatalities at all. EMAS is a generic term and is at the moment produced by four different manufacturers using three different techniques.
Contracting states have agreed to follow ICAO Standards and recommended Practices (SARPS) and needed to transfer these into their own national laws to become effective. Here start variations in interpretations. EASA, by example, almost copied the ICAO text in their regulation however with a vital difference: The replacement of "shall" into "should", changing an ICAO standard into a recommendation on RESA requirements. This leads to various interpretations and levels of safety and thus standards to be achieved.

2.1. ALARP

EASA Safety Risk Management (EASA NPA 2015-18(B)) describes As Low As Reasonably Practicable (ALARP) as "*Showing that the safety risk is ALARP means that any further risk reduction is either impracticable or grossly outweighed by the cost*".

Determining the ALARP of RESA is thus depending on the interpretation of aircraft operators, aerodrome operators, ANSP's as well as of the interpretation of the 28 EASA member states. ALARP is a function of safety, practicality and financial arguments. Financial repercussions of runway accidents can therefore be used as a common factor in Risks.

The consequences of a runway excursion for an ANSP might be re-routing and temporarily delays; for an aerodrome operator could it result in the temporarily closure of a runway, damage to equipment and handling of the occurrence; whilst an aircraft operator could loose an aircraft, be faced with full passenger compensations and severe financial and reputational repercussions.

$$\mathbf{ALARP} = \boldsymbol{f}\{\text{Safety gain, Practibility, } \mathbf{Costs}\}$$

For non-standard RESA's has EMAS the potential to reduce the runway excursion risk through specifically mitigating the severity aspect of a runway overruns. Analysis of cost-benefit of full RESA or EMAS provides an indication if runway overruns ALARP levels is cost effectively achievable.

2.2. Costs

2.2.1. Human

Injuries. Cavka and Cokorilo (2012) provide a method of calculating the cost benefit of aircraft safety, relate direct safety costs (DSC) to indirect safety costs (ISC), conclude that the financial losses are lower when timely the safety risk is determined and used Eurocontrol figures on injury calculations. These however do not differentiate the levels of injuries. The AIS Abbreviated Injury Scale (AIS) is coordinated with the medical sector and is since 1980 an accepted international method for trauma scoring in transport. Combining the number of injuries per AIS code with an average on medical treatment expenses per code would provide an indication of the injury costs per accident. Various papers on the costs of road traffic traumas indicate the cost for AIS (Zaloshnja, 2004; Ching-Huei). The US Economic counsil to the transportation Industry released in 2001 a system and figures based on the AIS. These figures are in line with other calculations. Costs other than Willingness To Pay (WTP) such as emergency services, medical care and legal and court services (excluding the costs of settlements) are to be added on an individual basis to the WTP values. Postma (2014) concluded that improved protocols are needed to counter the challenges of treating the sudden and large numbers of injuries in aviation accidents. Secondary effects to hospitals confronted with a sudden large number of victims are not enough taken into account yet.

Fatalities. In the period 1975-2014 a total of 17.558 people died due to air crashes averaging 439 people per year, Comparing the 4 decennia (1975-1984: 236/yr; 1985-1994: 506/yr; 1995-2004: 555/yr; 2005-2014: 459/yr) show no noticeable reduction in absolute numbers. However in the same period have the flown passenger kilometers quadrupled. It is therefore concluded that safety gain successfully compensates the growth in aviation traffic.
The 1999 Montreal (MC99) conventions established a modern compensatory regime in respect of passengers who suffer death or injury caused by an accident during international air carriage. It indicates a compensation of approximately $170 K per fatality. Kakalik et al. concluded that an average of $421 K are the real paid expenditures per aviation casualty. The cumulative US$ inflation since 1988 is 103,5%, leading to a 2015 compensation of $856,7K$. The 2001 ASTER report and Cavka and Cokorilo (2012), refer to the Value of Statistical Life (VOSL) and WTP for the European countries. These vary (1998) between 0,65M€ (Estonia) and 2,64M€ (Luxemburg). Applying inflation correction to the VOSL would give 2,96M€ (336 M$). The Economic counsel to the Transportation Industry (ECTI) advised the FAA in 2007 to use 3 M$ per casualty (+ 132K for WTP).

Conclusion - It can therefore be concluded that scoring aviation accident victims in accordance with the AIS provides a basis for estimating the severity of an accident. The costs are underestimated due to inflation correction and the lack of third party costs, such as the consequences of sudden treatment of large numbers of victims. No inflation for this paper is justified since a number of the researched runway excursion accidents occurred during the past 2 decades. Since all EMAS arrestments have been in the USA, are for this paper the FAA figures taken.

Table 1
AIS aviation costs

AI Co	Injury	Example	AIS % prob death	Total costs (200 dollars)
1	Minor	Superficial laceration	0	$10.500
2	Moderate	Fractured sternum	1 – 2	$55.600
3	Serious	Open fracture of humerus	8 – 10	$193.700
4	Severe	Perforated trachea	5 – 50	$703.100
5	Critical	Ruptured liver with tissue loss	May-50	$2.587.500
6	Maximum	Total severance of aorta	100	$3.123.700

2.2.2. Direct Safety Costs (DSC)

Both, Cavka and Cokorilo (2012) and ASTER, relate the DSC of an accident to the severity of the accident, the aircraft type and the aerodrome involved. ASTER differentiates and relates the severity classification depending on the level of damage to the aircraft and the number of fatalities. Although this table needs to be reviewed and updated *(e.g. it is doubtful if 50% damage to a A380 resulting in over $200 million damage, with 500+ injured passengers would still be classified as a "moderate" accident),* is the severity classification by ASTER taken as the best available at this moment.

Table 2
Aircraft damage levels definition

Level	Dama	Dea
Minor	15%	0
Moderate	50%	0
Major	80%	0
Disaster	100%	30%
Catastrophic	100%	50%

Source: ASTER consolidated report

The aircraft damage costs depend on the Current Market Value (CMV), which is a function of list price and age. Some publications use a generic figure averaging at 13% for the restorations costs of aircraft. NLR-ATSI differentiates and relates the aircraft repair costs to the level of damage: Minor 15%; Moderate 50%; Major 80%, Disaster and Catastrophic 100% of the aircraft CMV. ASTER estimates a loss of resale value between 5% and 10% of an aircraft involved in an accident, which obviously does not apply to full hull losses (Disaster and Catastrophic).
The accident aircraft needs to be replaced in order to maintain the same production capability during its downtime, that requires leasing an equivalent type. The price thereof varies with market availability, age and type. The monthly lease rates vary between 1.6% and 3,7% of the CMV. For simplicity is the lease price based on a 5 year-old aircraft (63% CMV and 2.0% monthly lease). Airline costs for not being able to provide planned production is estimated at 360k$ (wide body) and 150k$ (narrow body) per day. This is valid until the moment a lease aircraft resume production. For a wide body aircraft results that in approximately 3,8M$ and for a regional aircraft 1,25M$ per month. Business type aircraft are regarded as narrow body.
A runway excursion results in a closure of the runway resulting in delays and diversions. ASTER estimates the airline ground delay costs at € 22 per minute and € 33 per minute in the air. These are in the same range as the US FAA figures. Assuming an average of 40 departures per hour per runway are the ground delay costs estimated at 53k$ per hour.
IATA estimates the total diversion costs at 15k$ (narrow body) and over 100K$ (wide body) per aircraft. Diversion effects all aircraft inbound to an unforeseen closed runway. Aircraft not yet departed can be rerouted to an alternative destination; these are thus less affected. The diversion costs vary therefore between an estimated 600k$ (regional airport) and 20M$ (major hub). Diverting to another runway or airport causes also third party delays and additional safety risks. The extra costs associated with third party delays and the extra safety risk for diverting aircraft (low fuel, last minute re-planning, etc.) are not taken into account.
The costs of a runway excursion for an aerodrome include the costs for repair and not being able to use the runway for a certain (unexpected) time. Direct aerodrome repair costs include damage to runway and its surroundings (strip, RESA, EMAS, lights, (frangible) equipment, etc.). Additional costs such as removal of the wreckage, fire brigade, legal etc. are excluded in the DSC. Third-party repair costs (e.g. the TAM at Congonhas, warehouse and gas station), are also excluded in the DSC. No open source information on aerodrome direct repair and third party costs has been found, thus these are not rated in this paper (NR).
The opportunity costs consist of not being able to use the high value production asset: the runway. E.g. landing fees, passenger fees and taxes at major airports are estimated at $ 5k per aircraft. Having to close a runway could realistically cost up to $ 4,0M (50 movements /hour/ runway) per day (16 hours) for a major hub airport. The costs for regional airport is estimated at 200 K$ ($1k per movement/ 200 movements per day) for a regional airport. ASTER relates the runway closure to the accident severity: Minor 2 days, Moderate 2 days, Major 4 days, and Disaster and Catastrophic 5 days. These ASTER figures are used in this paper, although further research might provide an updated and more precise indication.

At 4th March 2015, veered Turkish airlines A330-300 of runway 02 of Kathmandu, collapsing the nose wheel, resulting in 4 minor injuries. Kathmandu closed the runway 02 for 3 ½ days.

EU Regulation 261/2004 regulates financial compensation for flight delays. These vary, depending on the type of flight and delay from € 250, €400 to € 600 per passenger. It might seem reasonable that accidents and or incidents would be excluded from passenger delay compensation. However jurisprudence on technical failures and birdstrikes indicates that passengers might also become eligible for compensation. The number of passengers affected is dependent of the type of flight, regional/intercontinental and number of daily flights (in and outbound) scheduled for the accident aircraft. It is assumed that regional flights have an average load of 100 passengers with 6 stretches per day and intercontinental flight 2 stretches, carrying 300. Thus the affected number passengers per day eligible for compensation are approximately the same and related the accident severity. Lost baggage compensation related to the severity of the accident is taken from Cavka and Cokorilo (2012).

Table 3
All DSC in one table

Classification	MINOR	MODERATI	MAJOR	DISASTER	CATASTROPHI

Source: Safe-runway GmbH

2.2.3. Indirect safety costs (ISC)

ISC relates to the investigation costs, search and rescue, recovery, legal and third party costs, loss of investment income, loss of reputation, increase of insurance premium, loss of business due to PR, etc. Various methods are available for calculating these. One method is to calculate each factor separately as provided the economic counsil to the US transportation Industry the FAA accident investigation costs. Although certainly possible to list all elements separately, used Cavka and Cokorilo (2012) a more practical approach by relating the Indirect Safety Costs (ISC) to the Direct Safety Costs (DSC) depending on the severity of the accident, which is used in our model.

Table 4
ISC-used - Indirect Safety Costs as a function of Direct Safety Costs

Classification	MINOR	MODERAT	MAJOR	DISASTEF	CATASTROPHI
ISC as a function of DSC	5%-15%	25%-40%	50%-70%	85%-110%	90%-140%
Median ISC as a function of DSC	10% DSC	32,5% DSC	60% DSC	97,5% DSC	115% DSC

Source: (Safe-runway GmbH)

Miscellaneous costs such as loss of company share value fines, punitive damage, criminal proceedings, extra legal costs, third party compensation fees, environmental fees, etc. are therefore not taken into account due to lack of sufficient data.

2.3. Cost-benefit of EMAS

10 Actual EMAS arrestment's provide an indication on the cost-benefit by comparing the financial consequences what would likely have happened in the hypothetical case that EMAS would not have been installed with the estimated costs of the actual arrestment's. The human costs, DSC and ISC are calculated for both scenarios are calculated based on the known specifics of the accident and using the assumptions as described.

The Toronto overrun as an example:
An 6 years old A340 overran runway 24L at Toronto Pearson with a speed of 86 knots, destroying the aircraft in a ditch / ravine. Toronto had no standard RESA, nor an EMAS bed. All 10 overruns into EMAS have been with very minor to almost no damage to the aircraft and no risk to the passengers/crew. A standard EMAS bed is designed for an entry speed of 70 knots for the most critical aircraft normally using the aerodrome. Let 's assume that the A340 would have vacated the EMAS bed with some speed, but less than 70 knots. It is very likely that enough energy would have been disseminated to cause only minor damage to the aircraft also. Calculating the runway excursion costs for this accident results in a total of 468,96 million$. Assuming there would have been an EMAS bed installed, the severity would have shifted from Disaster to Minor resulting in (hypothetical) accident costs of 67,21 million$. In the assumption that the aerodrome would have invested 10 M$ for an EMAS bed on runway 24L, the net savings would have been 401,75M$-10,0M$ over 390 million $.

Based on the available accident reports and FAA or open source document material are, as reasonably as possible, assumptions made in order to get to a reasonable indication of the possible consequences what could have happened if EMAS would not have been installed. These are than classified in line with ASTER into severity levels MINOR, MODERATE, MAJOR, DISASTER or CATASTROPHIC. All EMAS arrestment have been classified in the minor category, leading sometimes to overestimating the financial consequences. (e.g. a runway closure of 2 days (minor category) was in a number of cases only a matter of hours). Nevertheless is for the uniformity of the calculations the same method applied to all.
When data on consequences are clear from either the NTSB or the FAA report, these figures are taken. When not, then assumption are made to the best available most likely reasonable estimate. When more accurate data would become available, the calculations can be adapted accordingly.

Table 5
Estimated EMAS overrun costs

Occurrence	estimated costs with EMAS	Hypthetical costs without EMAS	Motivation
May 99 KJFK, SAAB34	Minor: $ 34	Disaster $ 229	high speed; Thurston Basin; substantial damage to aircraft, critical injuries, SOB 29
May 03 KJFK MD11	Minor $ 70	Disatster $ 263	low speed; before Thurston Basin; substantial damage to aircraft, major injuries, SOB 3
Jan 05 KFFK B747	Minor $ 73	Disaster $ 405	high speed; Thurston Basin; substantial damage to aircraft, critical injuries, SOB 3
Jul 06 KGMU Falcon900	Minor $ 13	Major $ 59	low speed; serious damage, serious injuries SOB 5
Jul 08 KORD A-320	Minor $ 55	Major $ 292	low speed knots; major damage, serious injuries SOB 145
Jul 08 KCRW CRJ200	Minor $ 10	Catastrophic $ 292	medium speed, ravine, destroyed, all fatalities SOB 34
Oct 10 KTEB Gulfstream 4	Minor $ 11	Disaster $ 107	medium speed, substantial damage, serious injuries SOB 10
Nov 11 KEYW Cessna 550	Minor $ 6	Disaster $ 46	medium speed, substantial damage, critical injuries SOB 5
Oct 13 KPBI Cessna 680	Minor $ 8	Major $ 34	low speed, major damage, serious injuries SOB 8
Jan 16 KPWK Falcon20	Minor $ 3	Major $ 20	Medium speed; highway; substantial damage SOB 2
Oct 16 KLGA B737	Minor $15	Disaster $ 276	Medium speed, external casualties at central parkway, SOB 48.

Source: (Safe-runway GmbH)

The total estimated costs (Million $) without EMAS are just over 2000, whilst the estimated accident costs are close to 300; thus 1700 has been saved. Standard investment in EMAS is estimated at 5-7, totaling the World Wide EMAS installations costs at 700, resulting in $1000 Million of net savings.

3. Conclusion

Combining the probability of a runway excursion with the financial consequences provides a concrete tool in a safety management system to address a specific runway excursion risk and bring that to the ALARP level. It seems that the duration of runway closure as used in this paper, derived from the ASTER logic, might not be accurate enough. Further research is recommended on the runway-overrun costs including all types of aircraft and aerodromes to derive to more precise data.
Nevertheless is the conclusion justified that mitigating the outcome of a runway overrun by a full 300 meters RESA or equivalent could be cost effective. The financial repercussions of a runway excursion are considerably larger for aircraft operators than for an aerodrome operator or an ANSP. Since aerodromes have to invest in a full RESA or equivalent, whilst the major financial benefits are for others, the decision making process to invest in this severity safety

enhancement is not optimal. The estimated net savings of $ 1 Billion for the industry as a whole justifies a joined approach. It is therefore recommended that the competent authority stimulate stakeholders to jointly find cost effective solutions for non standard RESA’s.

SESSION 2: HUMAN FACTOR IN TRANSPORT SYSTEMS

INSURANCE IN TRAFFIC AS AN ELEMENT OF INTELLIGENT TRANSPORT SYSTEMS - INFORMATION ASPECT

Barbara Rudić[1], Marko Pogarčić[2], Ivan Pogarčić[3]
[1,3] Polytechnic of Rijeka, Vukovarska 58, Croatia
[2] Municipal Court of Rijeka, Zrtava fasizma 3, Croatia

Abstract: ITS as an intelligent integral system equally implicit a complex structure of information system, as a functional format of real / material ITS. Pragmatically defined, the interest and need for quality ITS lies in transport stimulated problems and possibilities of usage of new information technology. That is why ITS could be defined as a holistic, controlled, information and communication version of a real system. Specific and unique possibilities which ICT provides in the domain of transport and traffic lie in the possibility of simulation with virtual models of real systems. Modelling and simulation of real system provide the creation of database. It can be used for describing situations which did not happen e.g. as a forecast. ITS is equally important in political elements of society safety. Surveillance of routes is important not only for safety of countries, but it is significant globally. ITS can be observed as a change in paradigm which is present in development of traffic discipline and in technology of transporting people and goods. ITS is a systematic managing and ICT solution which is (or it can be) incorporated in the network infrastructure, vehicles, monitoring centres and different ICT devices. This research examines information aspects of ITS in securing, measures and activities that can increase safety in transport. Types of insurance and compensation in traffic accidents are described, considering organizations that provide insurance in traffic. Insurance contract is considered through its concept, principles, participants and the insurance policy as a proof of insurance contract. This research analyzes the need for software solutions for insurance companies that complete ITS entirely. That is the only way to provide holistic accent of integral transport system. .

Keywords: ITS, ICT, traffic accidents, control of roads, traffic insurance contract.

1. Introduction

Transportation as economic activity is constantly developing, especially the road transportation. An impact of the road transportation on all human activities and its importance are relevant facts. That's why the transportation has an important role in modern society. There are different properties which can be treated apart when talking about the transportation. However, even when observing different features separately, a holistic approach should be considered and demanded (implemented, applied). Security problems in transportation will be examined separately from professional technological and legal viewpoints in this paper. To partially ensure a holistic picture, both viewpoints mentioned above are shown as one unit through basic settings of ITS which is a modern approach to transportation, and it necessitated the creation of integral information system. The integral information system isn't used in the flat- rate meaning, but it entails a complete integration of pieces of information related to core activities in the transportation with pieces of information that are important for all collateral activities on which the transportation as an activity relies. To be clear: security problems or for example traffic accidents have their material weights, but collateral facts/ information/ data can be relevant to some other activities. Permanent database establishment which can be updated and modified can be relevant for the broader social community. As mentioned, authors are interested in possibilities and specific conditions on a, conditionally speaking market, the opportunity to both using and providing pieces of information related to traffic safety from technological and legal viewpoints. There is a strong connection between insurance as a professional activity and transportation as an industry, in particular through the traffic of people and good insurance system. The road transportation safety will be examined apart while stating the main factors that influence the road transportation security and also insurance whose role is to enhance the traffic safety.

2. Defining the framework

The starting framework of this research is based on the definition and properties of the Intelligent transportation systems (ITS). ITS represents a combination or at least an intention to combine Information and communications technology (ICT) and transportation technology. Both mentioned technologies are components in function of factors management which are mutually intertwined and affect each other. Roads, vehicles, traffic regarding quantity and the traffic safety in the first place are all examples of the latter. Although both mentioned technologies are intertwined and complement each other and are of equal importance, slightly more will be told about the ICT significance, particularly about the integral information systems for a complete and efficient ITS.

.

2.1. Transportation as technology component of ITS

According to the definition, transportation entails a range of activities related to transportation of people, goods, but also information from one physical position to another. Transportation consists of transport infrastructure, vehicles and associated activities when materially speaking. Transportation classification is based on infrastructure and vehicles, but we should also note the fact that transportation is an economic-financial category, and it entails all the transport related

[1] Corresponding author: pogarcic@veleri.hr

activities and communications. When talking about transportation as a specialized activity, though, its realization requires transport infrastructure and total upgrade to ensure transport services. Although transportation and transport have almost the identical meaning, they aren't considered synonyms in this paper (Perallos at all, 2015).

On the other hand, a need for the ITS, as a general framework is a result of different activities. It's enough to take into account an increase in vehicle numbers to meet individual and group needs, general urbanization increase and changes it causes regarding the population density. There has also been recorded an increased impact of transportation on the environment through the air pollution and an increased fuel consumption, while decreased transport infrastructure efficiency results with traffic jams intensity increase, which exacerbates the quality of transport communication. (Horberry&Regan, 2014) The latter lead to utilisation of Information and communications technology (ICT) and the potential it provides in order to eliminate shortcomings and improve the quality of traffic. ICT is very practical and convenient since it enables "what if" type of computer simulation, "just in time" type of traffic control and a possibility to create and manage communication networks. Intelligent transportation systems (ITS) can be defined as a holistic, control and the ICT (cyber) upgrade of classical traffic and transport system which has significantly better performance, traffic flow, more efficient transport of passengers and goods, enhanced traffic security, comfort and safety of passengers, decreased environmental impact, etc. (Richard at all, 2002) The ITS signifies a new critical term which is changing the approach and the development trend of the Transportation Science and Technology of people and goods transportation, by efficiently eliminating rising problems of traffic congestions and environmental pollution, so as an increase of transportation efficiency and safety and protection of people and goods in traffic. In that way, an intelligent road represents a cyber and the ICT upgrade of classical roads which main differences are beside basic physical functions the following ones: better informing for drivers, better traffic management, safety apps, etc. (Williams, 2008) ITS is a system that provides services and pieces of information to the users via distributed information system while using the user- friendly interface for a user or a moving object, for both private and public sectors. ITS system has to be convergent and open-source, by providing, on the one hand, application of various technologies based on interactive and multimedia characteristics, and on the other hand, guaranteeing integrity action across a wide geographical area, from micro-locations to macro- locations. The main purpose of the intelligent transportation system implementation are to: raise the quality of traffic and transportation, enhance experiences of drivers and passengers, improve travel related procedures, exchange of goods and services and increase the overall traffic and information transparency. The primary goal of the ITS is, therefore, a system integration which will improve travels and transportation through more efficient and safer movement of people, goods and information together with greater mobility and fuel efficiency and less environmental pollution.

For the purposes of the paper it is necessary to emphasize the goals, which define more precisely the ITS, and those are the following ones: the increasing of the whole transportation system, the increasing of the mobility of people and goods, prevention and decrease of accidents and damages caused by transport, energy consumption decrease and long-term controlled environmental protection. The base of the ITS consists of system monitoring and ICT solutions as a part of the network infrastructure, vehicles, control centres and various ICT equipment. However, it is necessary to acquire a work definition of the ITS for purposes of singular viewpoints in this paper. The following definition is acceptable for those purposes: "Intelligent transportation systems (ITS) are advanced applications which, without embodying intelligence as such, aim to provide innovative services relating to different modes of transport and traffic management and enable various users to be better informed and make safer, more coordinated, and "smarter" use of transport networks." (DIRECTIVE 2010/40/EU.....) Thereby it is necessary to emphasise the importance of the ITS as a holistic, control and information and technology upgrade of the classical traffic and transportation system.

.

2.2. Holism and the ITS standardization

Although the European and the American viewpoints about the ITS integration are slightly different, the European perspective is considered to be the leading one when it comes to the domain of organised activities of the traffic and transportation. However, the implementation of the ISO standardisation has helped to achieve the full significance (Ortizar&Willumsen, 2011) (ISO/TC 204).

2.3. EU and the national frameworks of the ITS

Although ITS may refer to all modes of transport, EU Directive 2010/40/EU (7 July 2010) defines ITS as systems in which information and communication technologies are applied in the field of road transport, including infrastructure, vehicles and users, and in traffic management and mobility management, as well as for interfaces with other modes of transport. In accordance with above-mentioned at the national level, the Republic of Croatia issued the proposal of the National Program for the Development and the Deployment of Intelligent Transport Systems in the road transportation for the 2014-2018 period. Five national priority areas are planned to be covered by the National Program for the Development and the Introduction of the ITS in the road transportation for the 2014-2018 period as shown on Figure 1.

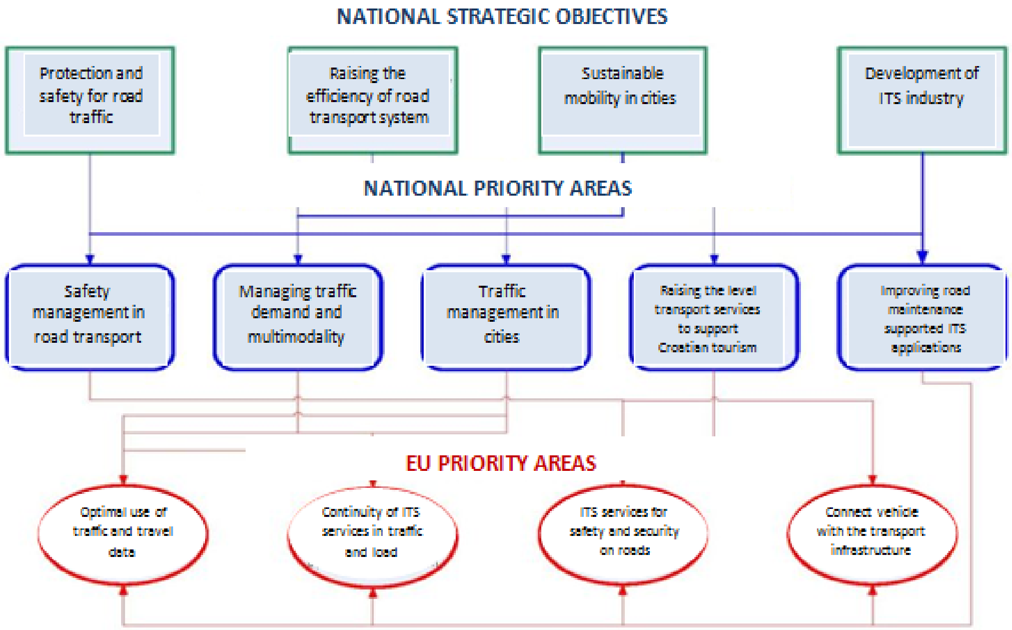

Fig. 1.
National Strategic Objectives
Source:http://www.mppi.hr/UserDocsImages/Nacrt%20Prijedloga%20Nacionalnog%20programa%20za%20uvodenje %20i%20razvoj%20ITS.PDF

The areas mentioned above are of national interest, and they emerged from the Action Plan for the Deployment of Intelligent Transport Systems in Europe, COM(2008) 886. It is the document which initiated a stronger focused deployment of the ITS in the road transportation in the field of the EU. The Action Plan is a result of experiences acquired in studies within ERTAC and ERTICO-ITS technological platforms and a need for a framework structure which would enable to harmonize the ITS deployment in the EU's road transportation. The Action Plan followed the public hearings and discussions between the key stakeholders and it is shown on Figure 2.

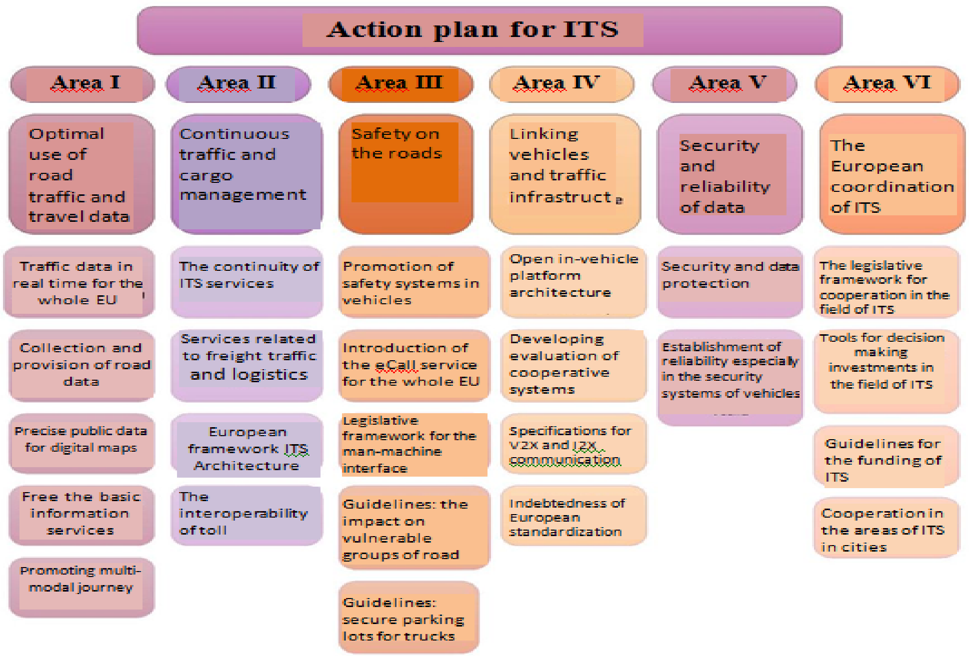

Fig. 2.
Action Plan for ITS
Source: DIRECTIVE 2010/40/EU OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 7 July 2010. eur-lex.europa.eu

2.4. Informational frameworks for the ITS- holistic approach problem

According to the content of the Action Plan and above mentioned ITS definition, it is of particular importance to insist on the holistic approach and integral solutions and the fundamental architecture of the ITS respectively. The simple reason why it is not possible to separate those two essential technologies of the ITS is the following one: although both technologies have different realisation, they belong to the same activities. To be more precise, the transportation wouldn't exist as an activity without a high-quality information support, whereas the information system wouldn't exist for its sake. When scrutinising the Action Plan and the list containing 32 essential services, it is possible to note the importance of the prompt and valid informing. Also, it is possible to envisage dimensions of such a system. Considering the requirements which this system meets, it is understandable that such a system has to be robust, dynamic and flexible both in structure and architecture. Frameworks in this paper are neither sufficient for a complete and detailed elaboration of nor technological, neither informatics component. (See more)(DIRECTIVE 2010/40/EU), (Sladkowski&Pamula, 2015).

The purpose of this paper is to emphasise the importance of the integral solution and especially the importance of informatics component organisation. It is, therefore, according to author's humble opinion, enough to hypothesise the working hypothesis which will, by using just one ITS aspect, clearly indicate the advantages of establishing a high-quality information system realisation. Although all the elements of the information system are equally important, its quality is mostly determined by both quality of its database, and data processing. That's the core issue since the prompt and valid informing of the users will depend on it. If we perceive it as a problem, it is clear that even the users will have to be a competent and capable of using the services of a system like ITS. It indirectly means that a user should be computer literate. It is clear that a high-quality database has to be organised and maintained by trained staff and professionals. However, it is also clear that the system with such a database enables the access to the interactive database, so as a possibility to update certain content quickly.

This point might sound a little bit too exaggerated or too ambitious from this point. Such impression can be obtained just at the first sight. Having considered some other systems with a similar way of functioning, indicates that such a quality can be implemented by a complete and active involvement of all stakeholders of such a system. To illustrate this point, personal, user and individual involvement in the usage of telecommunications, like mobile phones or even better Internet Banking and Mobile Banking systems, are enough to consider. The biggest issue, though, is to determine which and what kind of information will be needed and who, where, when and how they will be collected. It is clear that the information has to meet certain quality criteria. The implemented and planned activities related to standardisation of certain processes and events have already been mentioned. Since the established standardisation system on the informatics field already exists, a formation of firmly defined, but multiple sources information, shouldn't be a big problem. It's important to emphasise a chance for the user of such system to have multiple roles when it comes to different services requests within the ITS and other various requests for information.

2.5. Hypothetical case of the ITS utilisation

The modified hypothetical author's case is employed to illustrate the necessary services and data within the high-quality ITS. Suppose hypothetically: “Owner of an expensive automobile equipped with equally expensive devices that include GPS is a male person in his thirties. During a longer journey he has been using services of GIS system that is implemented into latest GPS device. During the journey he followed instructions given by GPS device, so he faced situation and circumstances on highway which mostly haven’t correspond to information provided by GPS device. In that specific situation the automobile has been completely ruined, while the owner has been experienced severe body contusions which haven’t threatened his life, but could contribute to consequences of minor body disability.” (Pogarcic, et al., 2012)

Although the authors put emphasis on GPS and GIS, it is clear that those are just components or elements which are a part of the ITS in full. To this possible case, it is evident that a lack of the right information in the first place is a cause of all the consequences emerging from the above mentioned hypothetical case. When observing the image No. 2 of the Action Plan more carefully, it is possible to notice that most of the areas stress the importance of the data. In that way, it is possible to notice not just a vertical correlation between different subareas, but also the importance of the horizontal correlation and area and subareas connectedness. Although the mentioned hypothetical case puts emphasis on the lack of a high-quality information, from completely one part of the information system, in the following deliberation the emphasis is beside information, to the user of those pieces of information, and to all potential users involved in similar events respectively. However, even when the situation is procedurally clear, there is a possibility that the participators won't understand the same term. The explanations are given to illustrate of the mentioned use case, but from the rights and obligations aspect emanating from the requirement of insurance of agents and persons in traffic. The damage is a term and legal institute defined by the Law of Obligations(in Republic of Croatia) (N.N.). (http://narodne-novine.nn.hr/default.aspx) The Law of Obligations unambiguously defines the damage types specifically as the violation of traffic participants personal rights. The traffic accident indemnity is prescribed by the Law of Obligations as both, *lex generalis* and *lex specialis*. According to the Law of Obligations, the victim of a traffic accident has to claim on the insurance company of the person who caused an accident. Together with the mentioned claim, the victim of a traffic accident submits a police report, medical record and other relevant documentation which proves the extent

of damage and expenses occurred before submitting the claim in order to prove and justify the required amount of money for the reimbursement.
The reason why the victim should claim on the insurance company, and not on the person who caused an accident personally, is the fact that doing so, strengthens the economic and legal security of the victim, and it also facilitates the obtaining of the required amount of money as reimbursement from the insurance company. Among all the required documentation in case of a traffic accident, a police report is of particular importance. It consists of all relevant data on a traffic accident such as: data on a police officer who writes a police report, data on the police department the police officers belong to, general and personal data on a victim and a person who caused a traffic accident that undoubtedly identifies them (full name, date of birth, residence address, personal identification number, national identification number and driver's license number). After obtaining personal data, the Report of Accident Occurrence is filled in with the following data (related to the description of the place where a traffic accident occurred): time of arrival of police officers at an accident, time of an accident, types of a car of the victim and the person who caused an accident, car brand and vehicle identification number, car parts damaged in an accident, position of the vehicle on a road, skid marks, etc. Then the following data is entered: weather and visibility conditions (whether the accident occurred at night or during the day), whether the road was slippery or not and whether water spots, oil stains or some obstacles were spotted on a road. Additional technical data include: whether an accident occurred on the straight or curvy part of the road, length and sharpness of a band and whether traffic signs were installed and were easily visible. Data about the concentration of alcohol and drugs, which can impair motor coordination and the ability to assess the weather conditions and other obstacles on the road, are recorded as well. Therefore, the Report of Accident Occurrence is a relevant documentation which can prove the accident occurrence and its authenticity. If an insurance company didn't comply with the requirement of a victim or it considered it unfounded, the victim would have a right to appeal to the insurance company. By filling a complaint, the victim initiates a civil action against the insurance company. The victim can arraign the mentioned claim, according to the Law on Civil Procedure, on the court of competent jurisdiction of the place where the accident occurred, residence address of the person who caused an accident or residence address of the victim. However, in a case of any dispute, there is a chance of presenting expert witness opinion testimony (Traffic Accident Expert Witnesses, Medical Expert Witness). After implementation of all evidence, the Court concludes the main discussion and renders a judgment which can adopt the plaintiff's claim or reject it as unfounded.

3. Summary as a conclusion

It is evident that a traffic accident, as a particular event in the security of the ITS, should be well elaborated, and all the pieces of information should be unambiguously defined. The previously mentioned fictive use case emphasized that the GIS as a system, police as an institution, judiciary as an institution, individual traffic participants, despite the type of traffic, share the same set of information and data set. However, every single stakeholder has own needs and own approach on that set. It doesn't exclude the need to define the database and that kind of information system- ICT component of the ITS which would be made according to the rules of positive trends in information systems development. The system should also have a certain hierarchical structure since it should meet requirements at the local, national and international levels. All in order to ensure integrated traffic security and quality. The recent information technologies and the information system structure- cloud computing and object- oriented approach from a technological point of view are more than enough for a realisation of the system with a high-quality database. The aim of this paper was to emphasize a need for such a realization and to point out the possibilities and advantages of the system. Most of the previous discussions were of course, just colloquial since the problems go beyond the limits allowed by a framework. It is clear that the authors will strive, in the following papers and deliberations, to insist on solutions which need to offer both holistic approach and solutions.

Abstract: Nowadays determination of driver's reaction time has become a main characteristic in the field of traffic accidents. Duration of driver reaction time is the main characteristic of driver himself and his behavior in the phase right before collision. This article is a part of an ongoing research project concerning innovative technique of biosignals' acquisition. The goal of this work is to distinguish and analyze driver reaction time and individual components of this reaction time (especially time needed for the decision and muscle response) and interaction between driver and vehicle in detail. For this purpose a combination of conventional methods, i.e. eye-tracking, and methods used for biosignals' acquisition, i.e. electromyography, has been proposed. Eye-tracking method is used to measure a view direction or eye movements relative to a head. This paper describes a use of the video-based eye-tracker combining a video images and a pupil reflection exploiting an infrared light. The driver's neuromuscular dynamic is important aspect of the interaction of driver and vehicle. Measurements of voltage during muscle activation (electromyography, EMG) are used to identify the muscles involved in interaction of driver and brake pedal. The main focus of this article is to determine all components of driver's reaction time involving experiments in real traffic. Additional evaluation is used as a basis for analyses of driver's behavior and reaction time in each respective situation. Results of this research could be beneficial for detailed investigation of the effects that have impact on the extension of reaction time which can lead to accidents.

Keywords: reaction time, eye-tracking, electromyography, driver, muscle response.

1. Introduction

Nowadays, trend of accident analysis researches has been tended to reduce the number of road traffic accident in every day driving conditions. The main cause of road accident is a human factor i.e. driver´s behavior. Police accident data confirmed that more than 90 percent of road accidents have been caused by human errors. It is important to know the driver behavior considering a road accident analysis and a road safety. The main personal characteristic is human reaction time (RT) as a time taken to complete a task.

In recent years, a work focused on the driver behavior has used eye-tracking methods. Eye-tracking methods have been used to measure a view direction or an eye movements relative to the head and have allowed monitoring, detecting and evaluating of visual sequences of drivers (e.g. Pfleger and Jechlinger, 2010; Pfleger and Hohenbüchler, 2011; Pfleger 2013; Kledus et al., 2013). Recently, eye-tracking methods have begun to be combined with an electrical potential measurement because of specification and more detailed analysis of reaction time. In a real traffic, an electrical potential measurements (electroencephalogram - EEG, EMG – elektromyogram, electrocardiogram – EKG and a heart rate variability, etc) are used rarely, they are used especially for a fatigue detection (Eoh et al., 2005; Katsis et al., 2004). These methods are used for verifying or calibrating of alertness systems frequently, typically EEG. Some recent studies have used combination of vehicle control information (steering, braking) and video capture for monitoring emotion with various physiological measures to assess the driver performance (Leenman et al., 2005; Michalski et al., 2004). In study (Mcgehee et al., 2010) combination of vehicle control information (steering wheel pressure) and video capture for monitoring facial state change has used to analyze non alerted driver response during a pre-crash.

In (Green, 2000) a literature review pointed out to a fact that the generalization of central tendency parameters (means or medians) taken from various studies did not take into account the important variance of drivers' RTs. He also criticized observed RTs values' distortion caused by using not strict unexpected situations especially in simulator studies. It led to bias and arbitrary estimate and shorter observed RTs. Therefore Green has suggested to that there should be more emphasis on the analysis and production of real data including driver reactions as a function of situational variables. Based on Green's suggestion the aim of this study was to analyze driver behavior in real traffic.

In general RT consists of three components – visual reaction time, psychical reaction time and physical reaction time. Visual reaction time is a time required to the object noticing (TON) and the visual fixation in the sharp vision area (TF). Psychical reaction time has been defined as a time between the visual fixation and the movement reaction time, it is time needed to object recognition by the central nervous system (CNS) and time needed to muscle activation. Physical or movement reaction time is a period of time in which the limb is moved from accelerator pedal (accelerator release time TA) to the brake pedal (TB). The goal of this work was to analyze and determine a time needed to object recognition in the CNS. In fact, it means the time needed to a decision about reaction and style of respond (TD = Time needed to decision). Use of electromyography allowed to determine the moment of muscle activation (TEMG). For the purposes of this study the muscle activity of the right lower limb was recorded by surface electromyography electrode

[1] Corresponding author: katerina.bucsuhazy@usi.vutbr.cz

system. Many studies analyzed the movement time (e.g. Pierson et al., 1959; Spirduso, 1975), but in this study the whole duration between the moment of muscle activation and activation of brake pedal (muscle response time = MRT) were investigated. Compared with the parameter of the movement time this parameter provided a more accurate picture of muscle work.

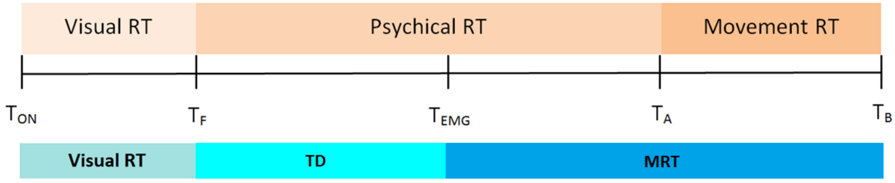

Fig. 1.
Driver reaction time

Primarily, this study was focused on the analysis of muscle activity and differences occurring during muscle work in different types of reactions in real traffic. Main conclusion in (Green, 2000) was that driver expectations are the most important variable affecting RTs. During the experiment in real traffic conditions three types of stimuli were included, unexpected stimulus (US), expected stimulus (ES) and critical braking as the reaction to the abrupt visual stimulus (CB).
In case of critical braking we tried to find out the shortest reaction time. Visual RT was eliminated by using the assumption published in (Bradáč, 1999), where it stated that if the angle of target is zero degrees, visual reaction time is null. Drivers were instructed before the beginning of the experiment on the short predefined route about the stimuli type, the required reaction, therefore time needed to the decision was reduced and due to this fact MRT was tended to minimize its duration.
Because of safety, use of dangerous and truly unexpected stimulus is not possible. As a compromise between the safety and the most unexpected stimulus a ball thrown in front of the driver at the one-way street was selected. Expected stimuli were objects found in real traffic (semaphore, pedestrian crossing street, STOP signs, etc.) commonly.
To ensure the comparability of responses, drivers drove on the same route. Four pedestrians stood at predetermined crosswalks. Many studies (Green, 2000; Pierson et al., 1959; Spirduso, 1975) confirmed the impact of age and gender on drivers' reaction time. This study was carried out with 12 men between 25 – 35 years.
In future, this research could be beneficial for driver behavior analysis of selected groups with some specific injuries or illnesses (e.g. Parkinson disease). Results are contributing not only to improve traffic safety, but they can be used in the road accidents' analysis. Future research should be beneficial for quantification of reaction time among selected groups.

2. Methods

The aim of this case study was to analyze driver reaction time in real traffic in detail. For this purpose, combination of eye-tracking method and measuring electrical activity of muscles was developed. To synchronize these two methods signals from both devices were marked at the same time moment by using the own device. The infrared LED was activated, the start time corresponded to the video frame in which the first LED blinking could be observed and to signal sample in which the level of the sensed signal from tibialis anterior was null.

2.1. Eye-tracking

Eye-tracker is a device that is used to measure eye movements. Eye-tracking method is used to measure motion of an eye relative to a head. The purpose of the eye movements is to fixate objects in the field of a view, in the area of sharp vision (foveal region). There are two main methods to detect the eye movements. In this research mobile eye-tracking Pupil was used.
Pupil is comprised by a light-weight headset with high-resolution scene and eye camera and can provide an average gaze estimation accuracy of 0.6 degree of visual angle. The video-based eye-tracker combinines a video images and a pupil reflection exploiting an infrared light [attachement, Fig. 1, Tab. 1]. An infrared light is shone into the eye and then it is reflected from the lens and sensed by a video camera (Kassner et al., 2014).

2.2. EMG

Generally for recording and evaluating the electrical activity produced by skeletal muscles the technique called electromyography (EMG) has been used (Merletti, 2004) and this method was utilized even in this project. The electrical activity of seven muscles of the lower right limb were acquired by using wireless surface and finewire EMG systems Cometa. In [attachement, Tab. 2] technical specifications of Cometa device are introduced. EMG system Cometa consists of two main parts. First part is a set of 16 electrodes which can be placed on the human body and this set serves to biosignal acquisition.

In this case seven electrodes were placed on the lower right limb Fig. 2: musculus iliopsoas as a primary mover of hip flexion; musculus gluteus maximus as a primary mover of hip extension; and musculus gracilis as a primary adductor of the hip joint. Postural changes of the knee joint were detected by recording from musculus quadriceps femoris (precisely rectus femoris) as a main mover of knee extension; and musculus semitendinosus as one of knee flexors. Movements of the ankle joint were monitored by measuring of electrical activity of musculus triceps surae as a primary mover of plantar flexion; musculus tibialis anterior as a primary mover of dorsiflexion and foot inversion; musculus peroneus longus as a main mover of foot eversion as well as foot abduction. Placement of electrodes was carried out in accordance with the SENIAM research group recommendations (Hermens et al., 1999).
First step of biosignal’s acquisition is recording signals into the external memory attached to the sensing electrode. Second step of biosignal’s acquisition is data transfer from external memory to the PC software where these data are processed and evaluated. In the [attachement, Fig. 2] the sensing electrode (number 1), which is placed directly on the one skeletal muscle, and the external memory (number 2) are introduced.
Second part of EMG system Cometa is a software for data processing. Acquired data can be processed offline and also data can be monitored in online mode. EMG data should be limited by 10-20 Hz from the bottom and 450-500 Hz from the top, therefore the software provides the basic data pre-processing by using 10-500 Hz band-pass filter.

3. Results

In the course of experiment every driver was exposed to two different types of braking reaction. First reaction was represented by gradual braking (e.g. expected pedestrian, red light on semaphore) and second stimulus was represented by swift braking (e.g. unexpected object, critical braking).
Analysis of visual component of reaction time should be made by eye-tracking technique. As mentioned in (Kledus et al., 2013), limitation of eye-tracking method and determination of visual reaction time is due to a situation which do not require significant changes of driver’s sight angle. In this work use of expected stimuli did not require the significant change of this angle, therefore if object was in driver field of view, visual reaction time was minimalized or null. Because of this reason visual reaction time has not been analyzed separately. In some cases visual reaction time could be a part of TD or it could overlap with TD. In the case of pedestrians, drivers sometimes reacted not to pedestrian but their reactions started at the moment they noticed the zebra crossing. In this case time needed to drivers’ decision started when they noticed the zebra crossing not the pedestrians.
TD has been determined as a time between visual fixation of object and start of tibialis anterior work. Tibialis anterior muscle is considered the muscle that firstly reacts in emergency situation (Seto et al., 2004; D´Addario et al., 2014; Gao, 2015). In case of critical braking, TD was minimalized by warning on visual stimuli during the predetermined route. Box plot in Fig. 3 of expected objects shows more significant span than other box plots. Maximum reflected the situations when object was totally expected and drivers had enough time to react, they analyzed situation and decided to react (or not to react). Low values reflected situations when object was on the border of predictability.
MRT time has been determined as a time between start of tibialis anterior work and activation of brake pedal. Indeed interesting results were obtained by a comparison of box plots for critical braking and unexpected stimuli (Fig. 3). Ball

thrown in front of driver in one-way street near children's playground was more stressful, so median of MRT time was smaller than median of critical braking. This fact was not able to be observed in TD, because in case of critical braking drivers knew the type of reaction (they were instructed to stop depending on the appearance of visual stimulus), therefore they did not need such a long time for a decision.

In an effort to leave the accelerator, functional chain of movements started by triple flexion of entire lower limb, including flexion of the hip joint, flexion of the knee joint and dorsal flexion of the talocrural joint (proper ankle joint). It was followed by internal shift of entire limb above the brake pedal accompanied by hip adduction. Closing stage was composed of triple extension of the lower limb, including hip extension, knee extension and plantar flexion of the talocrural joint. Plantar and dorsal flexions were connected with eversion or inversion according to the type of kinetic chain.

Commonly kinetic chains are divided into "open" and "closed" chain. Basically, during closed kinetic chain (CKC) the distal segments of the chain are fixed and proximal segments are moving. During open kinetic chain (OKC) the situation is inverse, when proximal parts are fixed and distal segments are moving (Wilk et al., 1996; Chang et al., 2014). In the open kinetic chain dorsiflexion is connected with the eversion, and abduction; and plantar flexion with inversion, and adduction. In the closed kinetic chain plantar flexion, is accompanied by abduction and eversion; while dorsiflexion is accompanied by inversion, and adduction (Rockar, 1995).

Results obtained by electromyography of the right lower limb shown us different muscle activity during various type of braking intention. Swift braking, as the reaction on the unexpected stimulus, induced isometric muscle contraction (visible on EMG as a rapid motor unit recruitment of all recorded muscle groups). By contrast, within gradual braking, as a reaction on the expected stimulus, sequential motor unit recruitment was noticeable. This muscle timing was typical for muscles of the ankle joint and foot, concretely, always after the expected stimulus the constant sequence came in the order given: m. tibialis anterior, m. peroneus longus, and m. triceps surae. It followed that braking reaction started by dorsiflexion with foot inversion induced by musculus tibialis anterior. It was compensated fast by the activity of antagonist muscle represented by musculus peroneus, which provoked foot eversion, because the main function of the peroneal muscles was to control the amount of the foot inversion and reflexively protect the ankle joint (Grüneberg et al., 2003; Ashton-Miller et al., 1996). The last step of braking was a step on brake pedal with strong plantar flexion induced by concentric contraction of the musculus triceps surae.

By observation of the mutual activity of the musculus peroneus longus and musculus tibialis anterior we are able to assume the functional stability of the ankle joint. Insufficient activity of peroneal muscles endangers stability of the ankle joint and does not allow distal segments to keep fixed position and to provide sufficient support for entire functional chain of the lower limb. This could have significant impact on stability of main body.

The investigated movement was bounded by the onset of tibialis anterior and the rising edge of footswitch signal (footswitch electrode was placed on the right sole). This bounded signal was analyzed in time and frequency domain. In the case of time domain analysis the time of the investigated movement was determined and in the case of frequency analysis the dominant and the median frequency was investigated.

In Fig. 5 muscles' activation during the critical braking in time domain is introduced. As mentioned above, the activation of three main muscles during the critical braking should be performed almost simultaneously and this fact can be seen in the red sector. From these signal's sets for all types of stimulus MRT was determined and compared with published results (Bradáč, 1999). In frequency domain the dominant (MNF) and the median frequency (MDF) of investigated time for all types of stimuli was determined by using periodogram method (Merletti, 2016). Signals' sections corresponding to the investigated times were turned into spectral domain and frequency representation was estimated. Illustration of one result from periodogram is introduced in [attachement, Fig. 3]. From this result the dominant and median frequency was found out.

Analysis in frequency domain was used to compare the signals from all types of stimuli. It was investigated whether the frequency representation of the investigated times changed depending on the type of stimulus by estimating the dominant and the median frequency. In Fig. 5 box-plots of MNF and MDF are introduced.

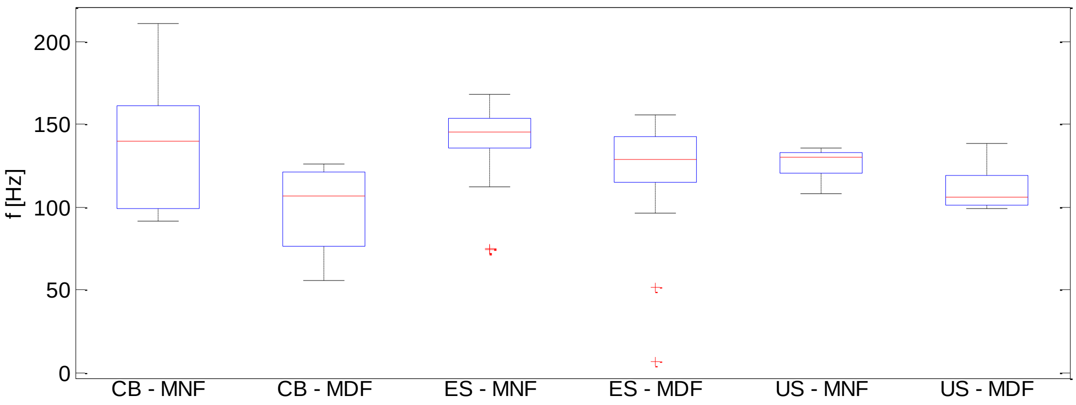

Fig. 5.
Box-plot of dominant (MNF) and median (MDF) frequencies

Finally, box plot in Fig. 6 provided the results of TD and MRT in sum. RTs for unexpected stimuli were in accordance of published results (Bradáč, 1999) and accident analysis used range, critical braking provided the lower border for RTs. Preview on the reaction time in real traffic provided results of RTs on the expected stimuli.

4. Discussion

The biosignals' acquisition can be viewed as a new approach how to analyze driver's manners in real traffic. For the acquisition of muscles' signals the set of electrodes placed on the lower limb has been designed. Duration of MRT and TD of the driver reaction can be founded by combination of electromyography signal acquisition and use of eye-tracking. Limitations of used technique (eyetracking) did not allow the analysis of visual reaction time in detail.
Critical braking results are characterized by the shortest RTs. In accident analysis the shortest values as this may not be used. Minimization of TD obtained by warning on visual stimuli on predetermined route, visual reaction time were eliminated because of zero angle of visual stimuli. Apparently the MRT was shorter in case of the unexpected stimuli unlike in case of critical braking. Prerequisite for this result is fact that the more stressful stimulus causes a higher risk of danger than the critical braking caused by the artificial visual stimulus. TD for the unexpected stimuli was estimated in conformity with published results (Bradáč, 1999). Results of RT analysis of the expected stimuli were characterized by considerable variation. It was caused by a large number of stimuli occurring in real traffic. Low values reflected situations when drivers did not expect the specified object. High values reflected the defensive drive, drivers did not react straight to the stimulus but to the upcoming situation in real traffic (e.g. driver reacted to the zebra crossing – upcoming situation, not to the pedestrian - stimulus).
Conclusions mentioned above were confirmed by statistical analysis. The analysis of variance (ANOVA) indicated significant differences among TD plus MRT of the expected stimuli and all of investigated parameters excepting TD of the expected stimuli. TD of the expected stimuli varied significantly from MRT of the expected stimuli. Duration of TD is dependent to the driver decision unlike MRT. Predictability of stimulus provided to drivers a large space for decision. If they decided to react, muscle response was similar in all types of the expected stimuli (therefore the variance of MRT was not so significant unlike TD). ANOVA was performed on the level of significance $p = 0.05$.
Obtained results revealed a fact that initial part of braking was first of all represented by dorsal flexion with inversion, which is typical for closed kinetic chain. After that, eversion with plantar flexion followed as is typical for closed kinetic chain too. Which means that direction of muscle contraction was from proximal insertion to distal, and distal segments provided functional support for moving proximal segments. The reason for this functional chaining could be impact of inertia.
It was found out that from seven monitored muscles of the lower right limb three skeletal muscles were involved in the investigated movement the most, m. tibialis anterior, m. peroneus longus and m. triceps surae respectively. Furthermore it was found out that in the case of expected stimulus these three muscles were activated gradually unlike the case of unexpected stimulus and critical braking where these three muscles were activated almost simultaneously.
The assumption was whether the value of the dominant frequency corresponded to the type of stimulus. In the context of our project, analysis in frequency domain should help to investigate muscles' activities during expected and unexpected stimuli and during the critical braking. It was found out that values of MNF and MDF for each type of stimulus were estimated in similar range. It means that level of muscle activity was comparable among all types of stimulus. Depending on the stimulus type the span of MNF and MDF varied markedly. MNF and MDF values (as well as MRT) of critical braking depended on the physical condition of participants the most.
Obtained results were analyzed not only in terms of duration but also in terms of physiology and function mechanism. This detailed analysis offers a wide range of applications for the analysis of reaction times of specific groups of drivers with diseases of the neuromuscular system. Contribution of this case study may be seen in use of the combination of conventional methods, i.e. eyetracking, and methods using biosignals' acquisition, i.e. electromyography, for analysis of reaction time not only for simulated conditions but also for stimulus commonly encountered in real traffic.

Abstract: Sight distance is a key factor in road safety. Sight distance estimation is usually performed on a digital terrain model (DTM). A DTM is a 3D representation of the terrain surface which depicts exclusively the elevation of the bare ground. However, the reality contains many more elements influencing sight distance than the bare ground. Features such as vegetation, traffic signs, buildings and many other elements are not included in DTMs. The first approximation solution involves the use of digital surface models (DSM), which comprise these roadside features. The use of geographic information systems (GIS) in highway safety research is interesting due to the easy integration of different factors (accidents, traffic data, road features) on the same software platform. However, sight distance studies based on DSM may lead to biased results when there are elements (for example, overpasses, tree branches or cantilever signals) overhanging the roadway that cannot be interpreted by those models. This paper proposes a method to overcome such difficulties. The proposed solution is based on GIS tools (lines of sight) and multipatch datasets, which represent roadside features adequately, added on the DTM. It has been applied in a rural highway located in the Region of Madrid (Spain).

Keywords: road safety, sight distance, geographic information systems.

1. Introduction

Sight distance is a key factor in road safety. In response to this, guidelines for geometric design of roads in different countries set minimum sight distance threshold values (Ministerio de Fomento, 2000; AASHTO, 2011; FGSV, 2012). In order to facilitate the geometric design of roads, some guidelines for geometric design of roads proposes a two-dimensional analytical methodology to estimate available sight distance. Particularly, Easa (2009) devised a 2-D method to calculate sight distance on sag curves with overpasses. Nevertheless, these procedures may not be practical since they consider separately horizontal and vertical alignment, which may lead to overestimate or underestimate the actual available sight distance (Ismail and Sayed, 2007). It is more common instead, to develop an algorithm based on line-of-sight loops on digital terrain models (DTMs), using therefore a 3-D approach. Such procedures retrieve the cross-sectional profile of the terrain below the line of sight between the observer and the target location, identifying any possible obstruction. Ismail and Sayed (2007) devised a precise algorithm to compute the available sight distance. Besides algorithms based on line-of-sight loops, procedures based on viewsheds were developed to study available sight distance of roads (Castro et al., 2011; Jha et al., 2011).
Computer-aided applications for road design estimate and compare available sight distances to stopping sight distance and passing sight distance. They also include visualization tools that simulate the driver’s perspective while travelling (Kühn et al., 2011; Castro, 2012). Such visualization tools are utilized to supervise proper 3-D alignment coordination, yet it requires this checking procedure is performed by experienced engineers (Larocca et al., 2011).
Methods based on line-of-sight loops enable the depiction of sight-distance graphs. These charts represent on the horizontal axis the stations where the driver is sequentially placed, and on the vertical axis the sight distance variables ahead each driver position (Kühn and Jha, 2011; Castro et al., 2014). Besides the comparison available and required sight distances, such charts are advantageous to evaluate the 3-D alignment coordination (Roos and Zimmermann, 2004; Jha et al., 2011; Castro et al., 2015). The German Road and Transportation Research Association provided a framework both for virtual perspective generation and sight-distance graphs on the design of rural highways (FGSV, 2008). Methods based on line-of-sight loops can be implemented on geographic information systems (GIS) (Castro et al., 2014). This approach is interesting because GISs enable that different factors and features may be treated and the data analyzed on a single software platform. For example, factors such as sight distance, geometric design consistency (Dell’Acqua, 2015), accidents, traffic data and road features can be studied together (Altamira et al., 2010; Castro and De Santos-Berbel, 2015).
A DTM is a 3-D representation of the terrain surface which depicts exclusively the elevation of the bare ground. However, the reality contains many more elements influencing sight distance than the bare ground. Features such as vegetation, traffic signs, buildings and many other elements are not included in DTMs. The first approximation solution involves the use of digital surface models (DSM), which comprise these additional roadside features (Khattak and Shamayleh, 2005). DSMs provide, in fact, further information about elements by the roadsides which could reduce the available sight distance. However, the intrinsic features of DSMs make difficult such sight distance analysis when using these entities that do not enable two points on its surface to have the same plan projection while their heights are different. This fact hinders a reliable representation of overhanging features, which is particularly awkward when they

[1] Corresponding author: luis.iglesias@upm.es

are partially located above the road, as occurs for tree crowns or cantilever signals. To overcome this issue, Castro et al. (2016) proposed to remove the overhanging part of these elements from DSMs. Campoy-Ungría (2015) proposed a procedure to estimate available sight distance on highways based on prismatic line-of-sight buffers launched directly on a high-density LiDAR cloud of points, not requiring any terrain surface.
This paper proposes an alternative method to address the problem of overhanging features on the roadway. The proposed solution is based on GIS tools (lines of sight) and multipatch datasets, which represent roadside features adequately, added on the DTM. It has been applied in a rural highway located in the Region of Madrid (Spain).

2. Materials and methods

The first part of this section describes the developed procedure for estimation of sight distance based on GIS tools and multipatch datasets. This procedure was applied to a road with a cantilever traffic signal. The case study is presented in the second part of this section.

2.1. Procedure

The developed procedure for sight distance calculations is performed using a geoprocessing model. This model is based on the use of Construct Sight Lines (ESRI, 2016a) and Line Of Sight (ESRI, 2016b) tools from the 3D Analyst extension of ArcMap. Line Of Sight tool may not only use a DTM and a file containing the points that define vehicle track, but obstructions consisting of a surface (multipatch).
The data required to launch this geoprocessing model comprises the theoretical path followed by a vehicle, a DTM recreating the highway and its roadsides and a multipatch model that includes the possible roadside obstructions to vision. Three stages have been followed so as to enable the study of sight distance:

1) **Terrain model processing**
   The DTM used with this procedure can be obtained from different sources. In this case, a high resolution scanning LIDAR was used to obtain the cloud of points. To create such model, the cloud of points needs first to be processed and classified. Whereas the points within the *ground* class will define the DTM, the points captured on the cantilever signal define another interesting point class in this case study. The scheme in Fig. 1 shows the procedure for processing those data. The point processing includes change of coordinate system as well as automated and manual classification. These operations were carried out using highly efficient, batch-scriptable, multicore command line LiDAR tools. These tools can be run via toolboxes for ArcGIS and are included in the LAStools software suite (Rapidlasso, 2016). The change of coordinate system was performed using *las2las* (transform), ground classification was performed using *lasground*, and manual classification was performed using *LAS datasets* tools of ArcGis,
2) **Construction of multipatch model**
   A multipatch is a 3-D geometry used to represent the outer surface, or shell, of features that occupy a discrete area or volume in 3-D space (ESRI, 2016). This type of geometry can be constructed with other non-GIS 3D software packages such as Collaborative Design Activity (COLLADA) and SketchUp.
   In order to build the multipatch model, the points identified as a cantilever traffic signal during the processing stage were used to set the dimensions of signal. These dimensions were used to define the multipatch model and build the model using 3-D design tools (3D Builder [Microsoft, 2016], and Google SketchUp [Trimble, 2015]). Once the model was built up, an interchange file format COLLADA was used to import the feature into ArcGIS. The exact positioning of model was performed in ArcScene, creating a new multipatch shapefile and using 3-D editor tools,
3) **Geoprocessing model launch**
   Geoprocessing model was built into ArcGis *ModelBuilder*. The procedure proposed was based on *Construct Sight Line* and *Line Of Sight* tools of ArcGis (Fig. 2). Prior to launch *Construct Sight Lines*, it is necessary to convert the 2-D point feature class into a 3-D feature class as well as to input the observer and target point heights. This was made using *Interpolate Shape* and *Calculate Field* of ArcGis tools. In order to apply the *Line Of Sight* tool, the computation model only considers lines matching the observer and stations ahead, up to a maximum given distance. After launching the *Line Of Sight* tool, a *Feature Layer* was created and added to a *Geodatabase*. Finally, detailed sight-distance graphs can be drawn if data are exported to a spreadsheet.

2.2. Case study

The procedure developed was applied on a two-lane rural highway (M-601) located in the Region of Madrid (Spain). A section including a cantilever traffic signal was selected as test site. Fig. 3 shows the actual appearance of the roadway and the roadsides in the section at the cantilever signal position. Fig. 4a shows the vertical alignment of the highway around the cantilever signal, located at station 950, on a grade between a crest vertical curve and a sag vertical curve. Fig. 4b shows the plan view, where the cantilever signal is on a tangent located after a horizontal left curve and before a roundabout followed by a horizontal right curve. The crest vertical curve overlaps, approximately, the horizontal left curve and the sag vertical curve matches, approximately, the horizontal right curve.

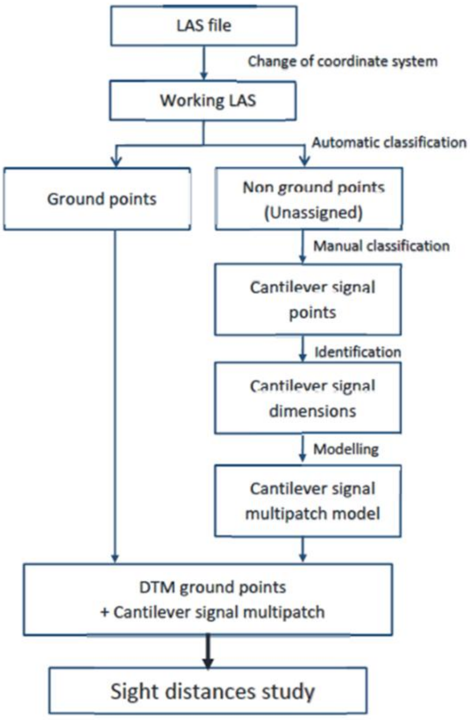

Fig. 1.
Terrain model processing schema

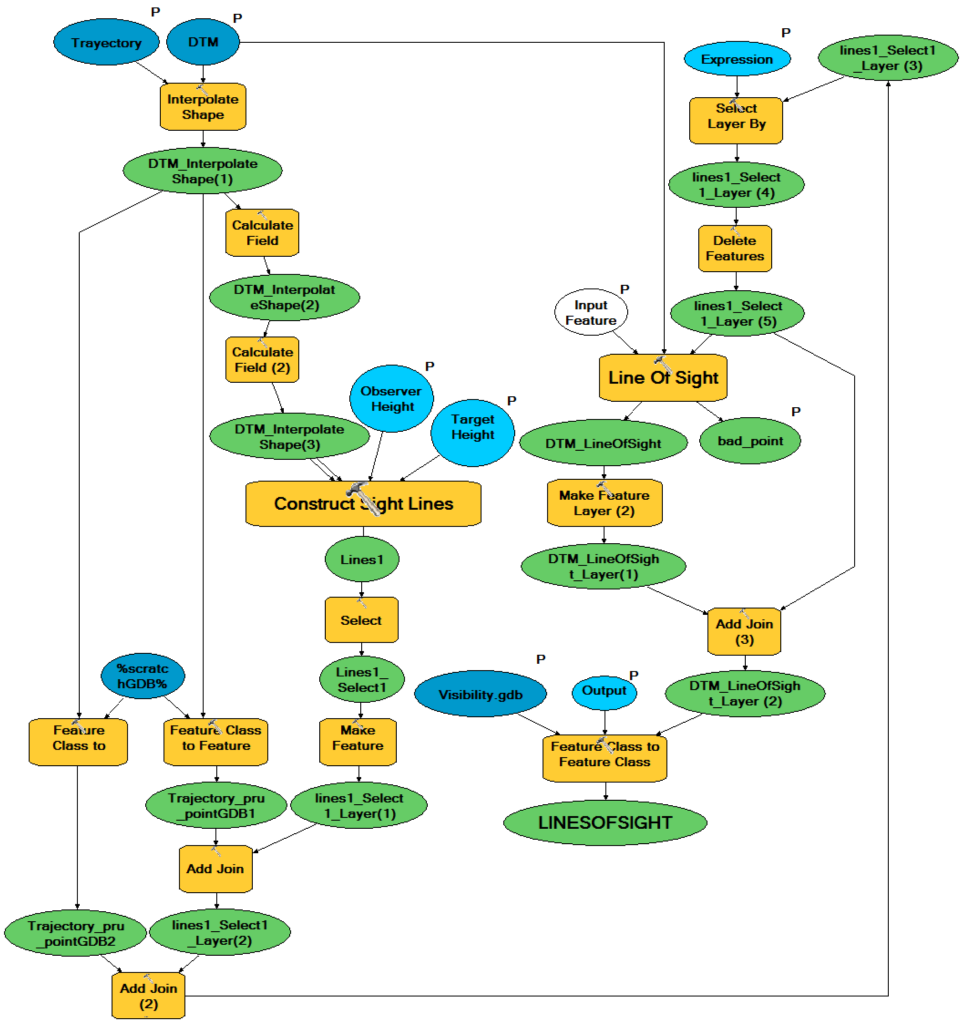

Fig. 2.
Flowchart of the geoprocessing model

Fig. 3.
Test site with cantilever traffic signal

First, in order to validate the new geoprocessing model, its performance is to be compared with the previous Add-in, developed by the authors (Castro et al., 2014), through the calculation of sight distance in four scenarios:

- Scenario 1: Using the previous Add-in and DTM (without cantilever signal),
- Scenario 2: Using the previous Add-in and DSM (including intrinsically cantilever signal),
- Scenario 3: Using the new geoprocessing model and DTM (without cantilever signal),
- Scenario 4: Using the new geoprocessing model and DSM (including intrinsically cantilever signal).

In these four previous scenarios, sight distance parameters took values according to the Spanish highway design standard (Ministerio de Fomento, 2016):

- Vehicle path: 1.5 m from the centerline,
- Driver's eye height: 1.1 m,
- Target object height: 0.5 m/

The vehicle path was extracted from the cartographic data of the highway. The two procedures for calculating sight distance use an algorithm based on line-of-sight loops, hence the vehicle path has to be defined as a discrete set of stations. They are spaced 5 meters apart along such path, where driver and target are successively placed while performing the loop. From each of those stations where the driver's eye is located, the application checks whether a target located in the stations ahead is actually seen or, on the contrary, the line of sight is intercepted by the DTM surface.

In all cases, roadway and roadside were modelled from a high-resolution set of 3-D points. These points were obtained through three LiDAR devices mounted on a car travelling along the road (Mobile Mapping System IPS2-Compact of Topcon). There were two sideward-oriented laser devices and a third one downward oriented, all of them installed at vehicle rear. Other components of the equipment are used for locating and orientating the survey. The GNSS device provides geospatial position, IMU device provides orientation and odometer the distance travelled, speed and angle of rotation of the vehicle wheels (Topcon, 2010). Vehicle speed during data collection was circa 50 km/h; consequently, the set of points is arranged in 12-centimetre spaced cross sections. As mentioned in previous section, the LiDAR devices saved the points in LAS format. Then, the LAS file was processed through the software LASTools so as to be usable on ArcGIS.

Additionally, four scenarios were studied using the new geoprocessing model, the DTM and the cantilever signal (modelled as a multipatch). As mentioned in the previous section, two pieces of software were used in order to build up the cantilever signal multipatch: 3D Builder (Blender) and SketchUp. The first one was used to build the model and the second one to export it as COLLADA format file. Finally, the COLLADA file was imported in ArcGIS. The characteristics of these four scenarios, including cantilever signal multipatch to validate the new procedure, were:

- Scenario 5: Using the new geoprocessing model, DTM (without cantilever signal) and cantilever signal modelled by multipatch. Vehicle path: 1.5 m from the centerline; driver's eye height: 1.1 m; target object height: 0.5 m,
- Scenario 6: Using the new geoprocessing model, DTM (without cantilever signal) and cantilever signal modelled by multipatch. Vehicle path: 1.5 m from the centerline; driver's eye height: 2.5 m; target object height: 0.5 m,
- Scenario 7: Using the new geoprocessing model, DTM (without cantilever signal) and cantilever signal modelled by multipatch. Vehicle path: 1.5 m from the centerline; driver's eye height: 6 m; target object height: 0.5 m,
- Scenario 8: Using the new geoprocessing model, DTM (without cantilever signal) and cantilever signal modelled by multipatch. Multipatch was displaced to station 900 m. Vehicle path: 1.5 m from the centerline; driver's eye height: 6 m; target object height: 0.5 m.

3. Results and discussion

Sight distance was studied for the validation of the new procedure on the eight scenarios set out and analyzed through the corresponding sight-distance graph. It is a chart in which stations are on the horizontal axis and sight distance, measured along the vehicle track, is on the vertical axis. Each green cell represents stations ahead the driver that are seen while the red ones depict non-seen stations, at the distance given by the vertical axis. Finally, the chart is characterized by a blue line which quantifies the available sight distance at each station.
Fig. 5 shows the different sight distance outcomes of the scenarios 1 to 4. Fig. 5a shows the sight-distance graph corresponding to scenario 1 (i.e. using the previous add-in and DTM). In this graph, the available sight distance decreases between stations 480 and 650 due to the horizontal left curve and the vertical crest. In contrast, it increases again as the driver leaves these alignments behind. Fig. 5b shows the sight distance results corresponding to scenario 2

(i.e. using the previous add-in and DSM, including cantilever traffic signal). Although the results of scenario indicate that there is a strong reduction of the available sight distance down to zero as the driver approaches the cantilever traffic signal (station 950), the actual visibility conditions greatly differ from that as it can be noticed in Fig. 3. This bias in the results flags the issue when using DSM since cantilever features cannot be shaped. Fig. 5c shows the sight distance results corresponding to scenario 3 (i.e. using the new geoprocessing model and DTM). Results from scenario 1 and 3 match at 99%. Similarly, Fig. 5d shows the sight distance outcome corresponding to scenario 4 (i.e. using the using the new geoprocessing model and DSM, including cantilever traffic signal). As occurred in scenario 3, there is a biased result in scenario 4 on the section prior to the cantilever signal. Likewise, results from scenario 2 and 4 match at 99%. Both scenarios 2 and 4 highlight the problems of sight distance studies based on DSM when there are elements such as the cantilever signal overhanging the roadway that cannot be correctly interpreted by those models.

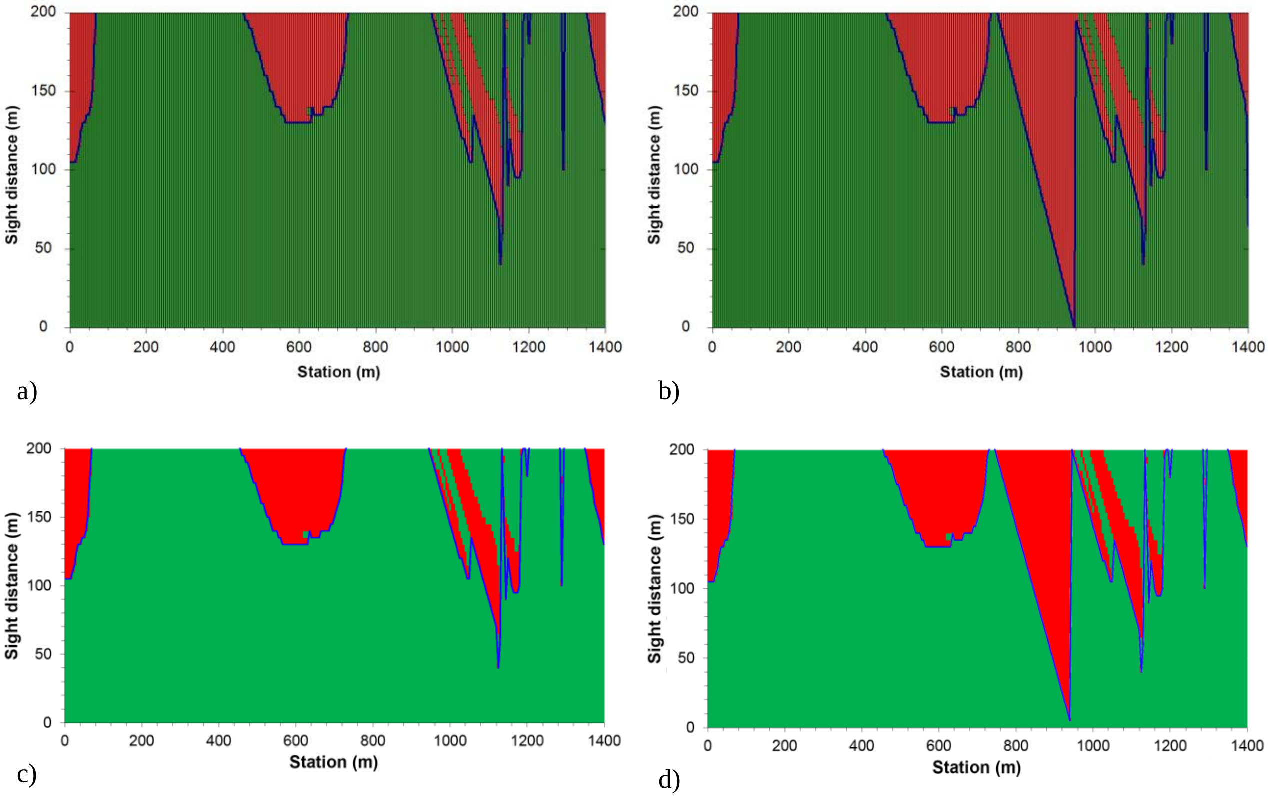

Fig. 5.
Sigh distance results: a) Scenario 1 (using the previous Add-in and DTM, without cantilever signal); b) Scenario 2 (using the previous Add-in and DSM, including cantilever signal); c) Scenario 3 (using the new geoprocessing model and DTM, without cantilever signal); d) Scenario 4 (using the new geoprocessing model and DSM, including cantilever signal)

On the other hand, Fig. 6 (scenarios 5 to 8) shows the outcome of the new procedure based on the new geoprocessing model, the DTM and the multipatch (the cantilever signal is modelled as a multipatch). Note that the new procedure, based on the geoprocessing model, uses the ArcGIS function *Line Of Sight* whilst the previous procedure (Add-in) use the ArcGIS function *Get Line of Sight*. *Line of Sight* function considers multipatches as possible hindrances to vision while the *Get Line of Sight* function does not. In the case of a car driver (driver’s eye height = 1.1 m), the cantilever signal does not reduce visibility (Fig. 6a). This occurs because the height of top and bottom parts of the cantilever signal above the terrain are, respectively, 7.5 and 4.5 m. It would be more likely that the cantilever signal reduces the visibility in the case of a truck driver (driver’s eye height = 2.5 m), but as this cantilever signal is on a grade, this does not happen either (Fig. 6b). From the comparison of Fig. 6a and 6b, it can be deduced that visibility conditions are more favorable for the truck driver than for the car driver as the red area in the chart is more reduced. These scenarios (5 and 6) show that the new procedure provides unbiased results (in agreement with the fact that the line of sight goes under the cantilever signal). However, in order to validate the new procedure, it is necessary to simulate a case where lines of sight intersect the traffic signal. Thus a driver’s eye height of 6 m was considered in scenario 7. Fig. 6c (scenario 7) shows indeed a sharp decrease of the available sight distance due to the traffic signal around station 950.
Furthermore, multipatch objects could be placed easily at any location. In this way, object (multipatch) location effect on visibility could be easily simulated. Fig. 6d (scenario 8) shows sight distance diagram corresponding to traffic signal location at station 900, displacing the multipatch backwards. In this case, the available sight distance is reduced due to cantilever signal at around station 900.

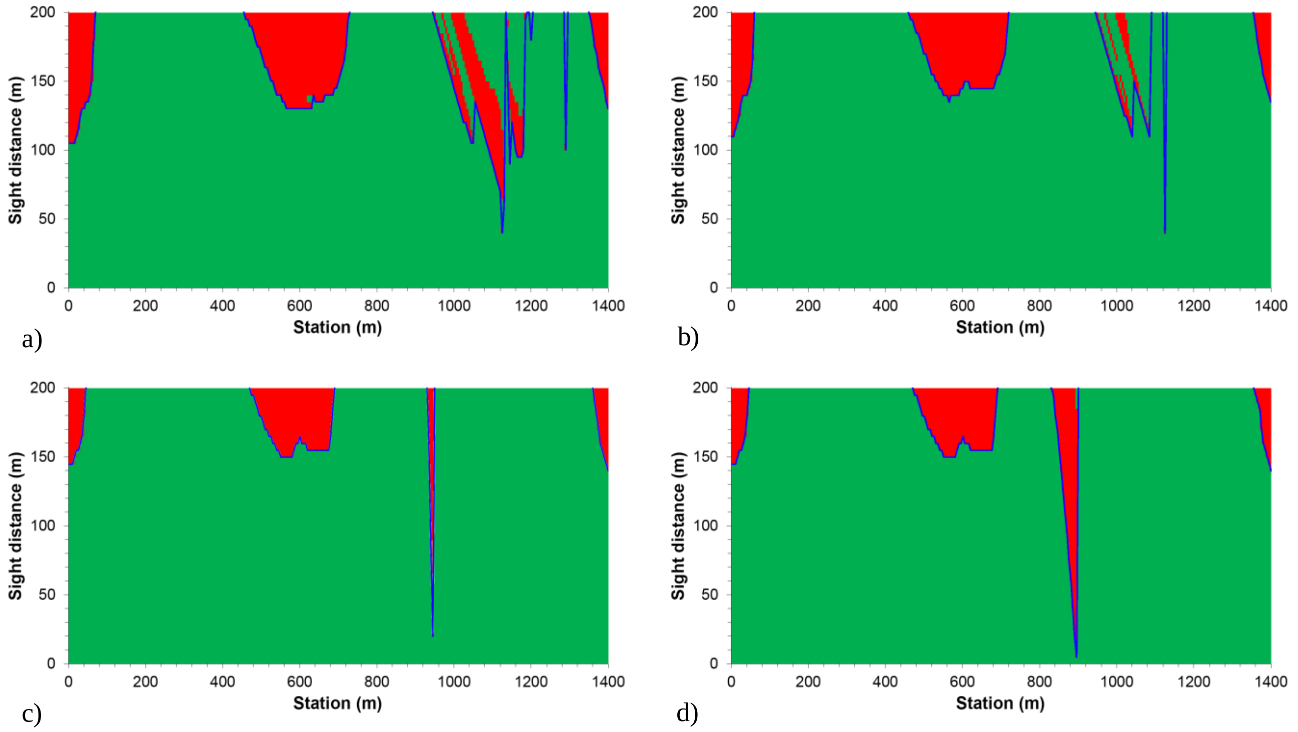

Fig. 6.
Sight distance results using the new geoprocessing model, DTM and cantilever signal modelled by a multipatch: a) Scenario 5 (driver's eye height: 1.1 m); b) Scenario 6 (driver's eye height: 2.5 m); c) Scenario 7 (driver's eye height: 6 m); d) Scenario 8: cantilever signal were moved to station 900 m; driver's eye height: 6 m

In this case study, the multipatch was built from a real element of the highway whose dimensions were determined by LiDAR surveying. However, due to the availability of multipatch datasets libraries, these studies could also be directly inserted. In this way, several objects could be simulated with less effort.

4. Conclusions

A new 3-D procedure for sight distance estimation was developed that overcomes the difficulties inherent to the presence of overhanging elements. This procedure was checked and validated by means of a comparison with a previously developed procedure. The new procedure is able to yield an unbiased sight distance outcome since, unlike procedures based exclusively on DTMs or DSMs, it builds up a real 3-D depiction of the highway and its roadside features. It may be useful, for example, to model either brand new or already-built highways where overhanging elements influencing sight distance such as trees or gantries could be present. This fact was shown by means of the cantilever traffic signal case study.
The easiness to place multipatch objects is an additional advantage provided by this procedure. This simplifies the simulation of object location to evaluate its possible effects on sight distance. Also, due to the availability of multipatch datasets libraries, modelling effort is reduced. Therefore, several objects on diverse locations could be easily simulated. Moreover, the use of GIS offers further advantages owing to its capabilities, the data integration, information management and analysis tools. Therefore different factors such as sight distance, accidents, operating speed, traffic volume and geometric features can be treated and analyzed on a single software platform.
As future lines of research, authors plan to apply this procedure to analyze the effect of overhanging elements on sight distance at or near sag vertical curves, overlapped with different alignments on the horizontal plan. Elements such as cantilever traffic signals could reduce drivers' available sight distance. Factors such as traffic signal location (station along the road), signal dimensions, clearance height and highway geometric design features will be taken into account.

COME RAIN OR SUNSHINE: REVEALED DIFFERENCES IN OBJECTIVE AND SUBJECTIVE USAGE OF ELECTRIC-DRIVE COMMERCIAL VEHICLES

Tadej Brezina[1], Maximilian Leodolter[2], Alexandra Millonig[3]
[1] *Vienna University of Technology, Institute of Transportation, Research Center of Transport Planning and Traffic Engineering,Vienna, Austria*
[2,3] *Austrian Institute of Technology, Mobility Department, Business Unit Dynamic Transportation Systems, TECHbase Vienna, Vienna, Austria*

Abstract: Delivery and business-services based on electric-drive vehicles are increasingly seen as components of an environmentally and socially compliant urban transport system. A model region named "e-Mobilty on Demand" was set up by Vienna's municipal utilities company which included the sponsorship for electric company cars – delivery or assembly vans – for various types of businesses. The authors were commissioned to study seasonal and weather-related influences on driver behaviour characteristics (e.g. speed, travel time, charging behaviour). A fleet of thirty cars from four different businesses were equipped with GPS-recorders and manual mobility logbooks. The businesses were two medium sized (tinsmith, chimney-sweeper) and two large sized (electricity supplier, telecommunications provider) companies. The survey took place over four periods of time: February/March and May/June in 2014 and 2015. The GPS data was connected with detailed temperature and sunshine duration records, as their impact has the biggest impact on battery life and performance. Their impact on driving behaviour was examined by means of cluster analysis. Additionally 66 drivers responded to an online survey on perceptions and experiences regarding electric vehicle usage. On average, trips took 20 min, went over a distance of 7 km and had a speed of 39 km/h. In a detailed analysis of driving speeds, trip durations and lengths for different weather conditions no significant impact could be found. The hypothesis of a weather-based change in usage could not be supported, neither concerning length nor duration of trips or driving speeds. Logbook data analysis showed a significant share of en-route battery charging taking place outside the batteries' recommended state of charge. The online survey shows that the participating drivers claim to adapt their driving behaviour to climate conditions, a notion which could not be backed by objective GPS data. Future work could deal with differences in driving behaviour of private and company cars.

Keywords: electric commercial vehicles, company fleets, electric driving behaviour, weather impact.

1. Introduction

In the framework of the Vienna public utility company's model region "e-Mobility on Demand", battery electric drive vehicles (BEV) were included in business fleets by different companies. The model region focuses on the practical use of electric drive vehicles differs instead of conventional fossil-driven vehicles. The task of our research was to survey whether differences in subjective and objective user behaviour could be identified under different weather conditions in terms of number of trips, length of trips and speed (Brezina, T., et al. 2015; Leodolter, M., et al. 2015). As the survey was commissioned after the adoption of BEV to the model region, no differences between fossil fuel vehicles and BEVs could be studied. One major barrier to introducing BEVs is the fear of potential users that range would be insufficient in comparison to fossil fuel vehicle standards (Franke, T., et al. 2012; Prandtstetter, M., et al. 2013). Car buyers seem to prefer vehicles with high available range, although these preferences decrease with practical EV experience (Franke, T. and Krems, J. F. 2013). Not only is range anxiety considered as an introduction barrier among potential users, but research also predicts meteorological influences on energy demand as a base of range optimization (Yuksel, T. and Michalek, J. J. 2015; Viehl, A., et al. 2016). Range anxiety and auxiliary energy demand have been subject of previous research (Graser, A., et al. 2014; Asamer, J., et al. 2016). Our study departs from previous studies by objectively surveying user notions of range anxiety and battery insufficiency in the field of commercial vehicle usage.
In the following section the materials and methods that were used are introduced. Section three summarizes the results of both, subjective and objective data, and in the final section the results are briefly discussed and conclusions based upon them are drawn.

2. Materials and Methods

In order to develop a comprehensive picture of behavioural patterns between summer and winter operations, a tri-polar research design was chosen (Fig. 1). The survey took place over four two-month-periods, in order to cover the widest possible spectrum of seasonal and weather-induced potential influences on driving behaviour:

- February & March 2014,
- May & June 2014,
- February & March 2015,
- May & June 2015.

[1] Corresponding author: tadej.brezina@ivv.tuwien.ac.at

Fig. 1.
Tri-polar survey design incorporation: GPS tracking, manual mobility logbooks and an online user survey to span the bridge between objective movement data and subjective appraisal by users

For the survey of objective behaviour, GPS-recorders and manual logbooks were installed in a fleet of combined 30 cars of two medium sized (tinsmith, chimney-sweeper) and two large sized (electricity supplier, telecommunications provider) companies. The car fleet comprised of following types: Renault (Kangoo, Trafik, Zoe), Tesla (S), Nissan (Leaf) and Citroen (Berlingo, C-Zero). GPS data were revised for errors, stops and finally connected with detailed records of temperature and sunshine duration, as their impact has a significant impact on battery life and performance (Yuksel, T. and Michalek, J. J. 2015).
Subjective appraisal was queried by an online poll that was sent to the users of the car fleet. A total of 26 questions were clustered in three blocks: private interest in e-mobility, appraisal of e-mobility use in business and finally respondent characteristics. The appraisal block included among others questions on in-use experience, charging frequency and the appraisal of the weather's influence.

3. Results

The subjective appraisal resulted in 54.8 % of respondents (n=66) reporting to have experienced special conditions during very hot or/and very cold days (Fig. 2, left). In particular, 43.6 % of respondents reported to have turned off auxiliary functions such as heating, cooling, navigation devices, internal lighting or the radio in order to preserve battery charge. Moreover, 46.2 % of respondents asserted that they schedule their trips in terms of length and duration based on battery conservation (Fig. 2, right).

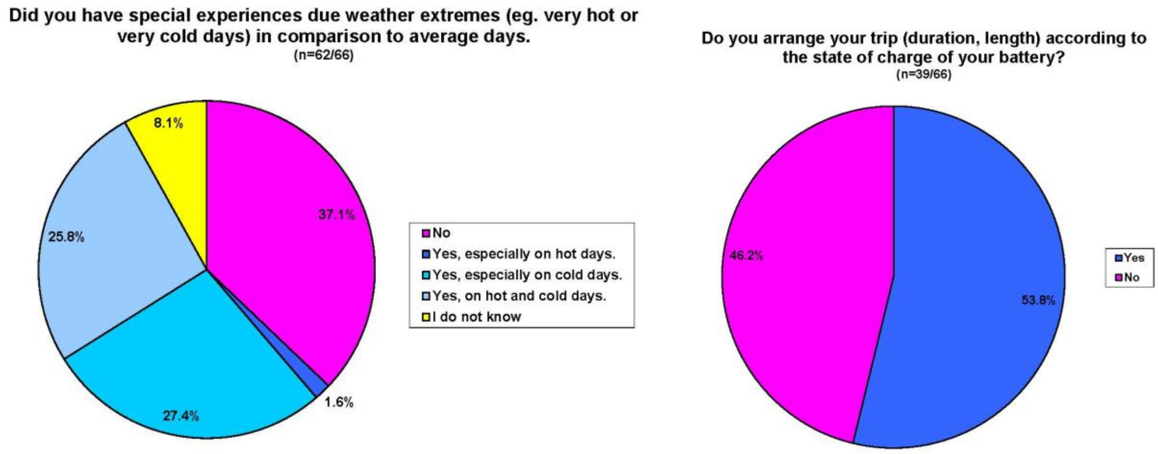

Fig. 2.
Left: A majority of respondents claims to have had special, weather induced experiences with their e-cars in hot and/or cold days. Right: Respondents claim with a majority of 53.8 % to arrange their trips according to trip length or duration

Logbook data analysis on the other hand showed a significant share of en-route (stops outside the vehicle's home base) battery charging taking place outside the batteries' recommended state of charge (SOC). Battery life is enhanced, when they are recharged in a SOC range between 20 and 80 % (Leitinger, C. and Litzlbauer, M. 2011; Budde-Meiwes, H., et al. 2013). Batteries shall therefore never be recharged neither full nor empty. Recharging data shows that about 30 % of the recharging took place in the non-recommended SOC range (Fig. 3, left). E-vehicle users were also asked to rate the additional loading (materials, tools, personnel) of their vehicle for each trip from no additional loading (0) to maximum additional loading (3). When looking at battery recharging from the loading perspective, light additional loading leads to 7-12 % earlier loading. Heavier additional loading leads to less pronounced recharging behaviour (Fig. 3, right). In addition the vehicles in operation were distinguished by type (personal car vs. light-duty commercial vehicle) and by usage profile (permanently assigned to one driver vs. part of a vehicle pool with different users). Similar cumulative frequency distribution reveals that private cars were charged with 10 % fuller batteries in comparison to light-duty commercial vehicle usage. In the SOC range from 45 to 85 %, pool vehicles were charged with approximately 5 % fuller batteries (earlier) than when assigned to one driver only.

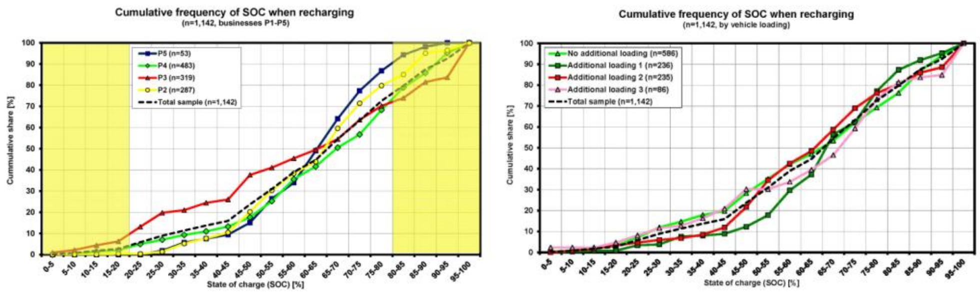

Fig. 3.
Left: Cumulative frequency of SOC when recharging batteries en-route, distinguished by the four participating businesses. Shaded areas indicate SOC ranges that are not recommended for recharging. Right: Cumulative frequency of SOC when recharging the batteries en-route, distinguished by four classes of vehicle loading, from no additional loading (0) to maximum loading (3)

Behaviour parameters from GPS tracking data are presented in Table 1. On average, trips took 20 min, went over a distance of 7 km and reached a speed of 39 km/h.

Table 1
Trip characteristics from GPS data

	Min	Median	Average	Max
Duration [min]	0	15	20	1,377
Distance [km]	0	4	7	287
Velocity [km/h]	1	36	39	148

Fig. 4 depicts distributions of trip durations differentiated by weather conditions, which are represented as weather-classes (e.g.: temperature of -2.9 to 6.8 degrees Celsius and 0 to 38 percent of sunshine per hour). To achieve a continuous data distribution across different weather-classes, the interval borders were defined as the quartiles for the temperature and as the median for the sunshine, respectively. The histograms show highly similar data structures. So, based on this plot significant differences in trip duration could not be expected. Further analysis of the data included similar approaches for the trip speeds. The hypothesis under investigation is that the driving behaviour is similarly adjusted under different weather conditions; e.g. on very hot and very cold days, so that air conditioning and heating affect the driving speed in an analogous way.
The first step towards the examination of this hypothesis is to separate the weather conditions using a finer granulation (see Fig. 5). The second step focuses on finding similarities of these weather classes by performing a clustering based on the Cramér-von-Mises[2] statistic as adjacency measure. The dendrogram in Fig. 6 demonstrates the results of the clustering. The green cluster appears to have a higher median of speed. After omitting the clusters 2, 4, and 6 due to lack of data and small cluster size, only three clusters remain: 1, 3 and 5. A non-parametric permutation test proves that the location shift of the clusters 1 and 3 to cluster 5 are statistically significant. So, taking the weather conditions represented by cluster 5 into consideration, the average driving speed drops by about 2 km/h.

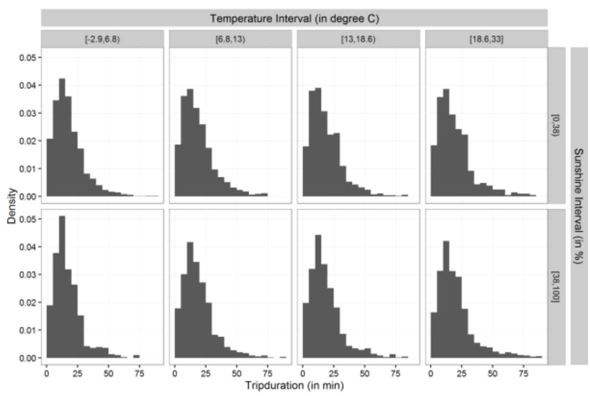

Fig. 4.
Histogram matrix of trip duration in minutes clustered by intervals of temperature (in degrees Celsius) and sunshine duration (in percent)

[2]The Cramér-von Mises statistic is used in statistics to compute the deviations of two empirical cumulative distribution functions (CDF). It is defined by the integral of the squared Frobenius norm of the difference of two CDFs.

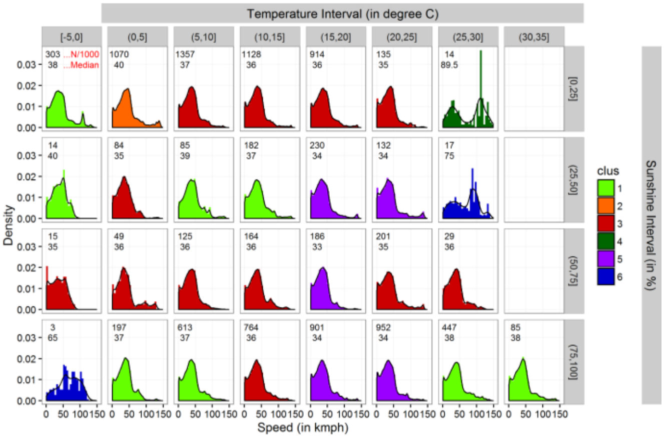

Fig. 5.
Histogram matrix of trip speeds by Cramer-von-Mises statistics, clustered (according to Fig. 6) by temperature and sunshine intervals. The numbers in left upper corner represent the sample size (n/1,000) and the sample's rounded median

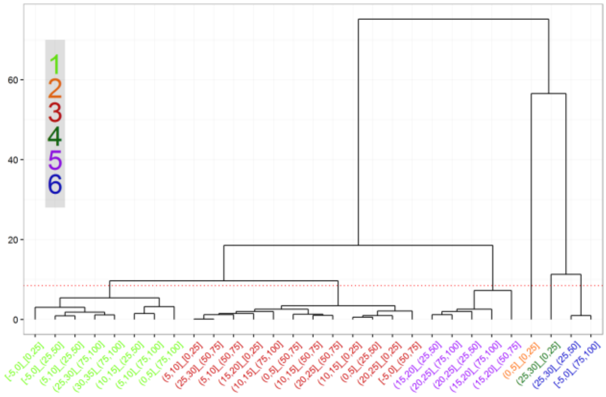

Fig. 6.
Dendrogram (agglomerated, hierarchical clustering) of temperature and sunshine interval samples reveals six clusters

Further in-depth investigation of the speed records and their starting time reveals a possible explanation for the distributions with only non-direct relationships to weather data. An over proportional share of trips of cluster 5 started about 2 hours later than those of cluster 1 and 3. This means that cluster 5 collects mainly trips starting during the morning rush hour, whereas trips of cluster 1 and 3 already start in the early morning hours (Fig. 7, upper). These earlier starting trips may not be hindered in speed choice by the morning peak hour. The morning peak hour reduces cluster five's average speed and thus alters its total distribution. Sunshine duration and temperature are expected to increase during late morning hours. The lower part of Fig. 7 shows the change in speed over the course of the day for the three aforementioned clusters. Therefore, a direct dependency between weather conditions and driving speed cannot be drawn.

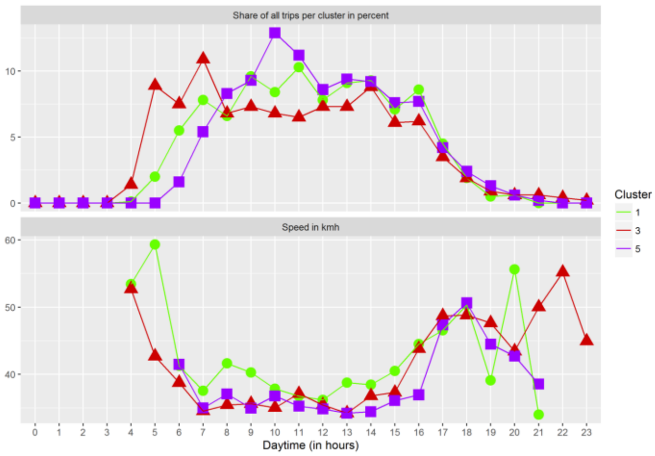

Fig. 7.
Distribution of trip starts for clusters one, three and five (upper) and distribution of average trip speeds (lower) by time of day

4. Discussion and Conclusion

The recorded en-route recharging data show that about thirty percent of recharges take place outside of the recommended SOC. The main reasons may be either driver's lack of knowledge regarding correct recharging procedures or movement-work-pattern constraints – craftsmen recharging their cars when opportunities arise at construction sites and not when it is best for the batteries. While up to 55 % of questionnaire participants stated in the survey that they would act preventively for battery charge conservation under very hot/cold weather conditions by adapting their route choices, a detailed analysis of GPS tracking data could not support these claims. Trip duration and speed datasets were referred to temperature and sunshine interval data. The resulting clusters showed no significant relationships. Subjective driver's notions of adapting their driving behaviour to climate conditions could thus not be backed by our objective GPS tracking data. Neither duration, nor distance, nor velocity showed direct correlation with weather conditions. In the case of one cluster, we speculate that its later trip starts resulted in higher speeds due to the already decreasing morning peak hour. It appears that general insufficiency anxiety of electric vehicles is not based on objective evidence but on other factors, such as individual experience and psychology. Such objective data may provide a sound basis for business decisions concerning car fleets.
Future research may focus on the survey of charging behaviour and movement patterns in depth in order to improve longevity of batteries. Further work could also investigate possible differences in driving behaviour between private and company cars.

Abstract: Despite the higher accident rates during night driving compared to those in daylight, little research has been conducted on nighttime highway safety. Nighttime sight distance is one of the most relevant factors in night driving. Current design guides provide two dimensional models to study nighttime sight distance in order to design sag vertical curves. These models may, nonetheless, underestimate or overestimate the available sight distance because they do not take account of possible combinations with horizontal alignment nor the actual roadside obstructions. It is therefore necessary to develop a three-dimensional (3D) procedure capable of analyzing the available sight distance under nighttime conditions. This way, it is possible to set the basis of nighttime driving safety research. Thus the study of nighttime sight distance could help in determining whether highway geometric design or headlamp features may influence accident-prone locations. The aim of this study is to analyze the influence of the headlamp lighting parameters on real highways and compare the nighttime sight distance outcome to that in daylight. A GIS-based application for sight-distance studies with a specific tool for nighttime sight distance has been used. The headlamp parameters studied were beam range, headlamp height, upward divergence angle and horizontal spread angle. The analysis has been carried out on different real highways, which enabled the study of the influence of each parameter on different 3D alignments.

Keywords: road safety, nighttime sight distance, headlamp.

1. Introduction

Despite the higher accident rates during nighttime driving compared to those in daylight, little research has been conducted on nighttime highway safety. Nighttime sight distance is one of the most relevant factors in night driving. Studies demonstrated the need for use 3D methods to estimate daytime available sight distance. This fact may also be applied to nighttime available sight distance. Moreover, not only has the combined effect of horizontal and vertical alignments to be known, but also the influence of adjacent alignments is relevant.

When a vehicle traverses a sag vertical curve at night, the stretch of highway illuminated ahead depends on the position of the headlights and the direction of the light beam. Current design guides provide two dimensional models to study nighttime sight distance to design sag vertical curves. However, the diversity of headlight features and layouts has not been properly incorporated in geometric design neither their impact on the visibility conditions produced.

The procedure presented hereby is an extension of the GIS-based daytime sight distance application developed by the authors (Castro et al., 2014). This paper analyzes the effect of headlamp lighting parameters on unlit rural highways under nighttime conditions through the study of an in-service highway.

2. Background

Statistics indicate that nighttime accidents are more frequent than those occurred at daytime even though the traffic volume registered during the night is significantly lower (AASHTO, 2011). In fact, 32 % of fatalities occurred on highways in 2013 in Spain were at dusk or nighttime and 61 % of pedestrians killed befell on rural highways (DGT, 2014). It is therefore necessary to intensify the research on nighttime highway safety.

The enhancement of highway design has produced evident benefits for safety and comfort. However, generous alignments might have also created potential challenges by enabling higher speeds (Dell'Acqua, 2015). On the one hand, Rockwell et al. (1970) reported that drivers adopt higher speeds at nighttime as the available sight distance increases. Limited sight distance under nighttime conditions, on the other hand, reduces reaction chances to road users (Adler et al., 1973).

Design guides propose two-dimensional (2D) analytical methods to device alignments that enable sufficient visibility conditions both on daytime and nighttime conditions (AASHTO, 2011; Ministerio de Fomento, 2016). Recently, the prescriptions for sag curve design were reviewed (Gibbons et al., 2012). It was observed that a static object on the roadway was detected by drivers from distances significantly shorter than those assumed on stopping sight distance models, regardless of the vertical element type. It follows that the limiting factor is often the lighting conditions rather than the highway geometry.

To apply sight distance as design criterion, guides consider separately highway plan and profile. Such practices may nonetheless lead to underestimate or overestimate the actual sight distance yielded as they ignore the combined effect of alignments and roadsides in three dimensions (3D) (Hassan et al., 1997). Ekrias et al. (2008) measured and analyzed traffic lighting features to simulate automobile headlights. Hassan et al. (1997) developed a procedure to compute the available sight distance in 3D on theoretical alignments. Horizontal and vertical curves overlapped were studied. It was

[1] Corresponding author: cesar.desantos@upm.es

observed that a wider horizontal spread angle enhances visibility up to an extent that depends on the highway geometric design. It was also confirmed that superelevation improves visibility. Sivak et al. (1998) evaluated the effects of a variety of factors on the photometric performance of low-beam headlamps.

AASHTO (2011) assumes a headlight mounting height of 0.60 m and a 1 degree as the upward divergence of the light beam from the longitudinal axle of the vehicle. This height value is at odds with that recommended by the Spanish design standard (Ministerio de Fomento, 2016) or the Portuguese one (JAE, 1994), which set the headlight height at 0.75 m. As might be expected, assuming a lower headlight height lays on the safe side. Thus, it is necessary to provide insight on the influence of this height value. For example, the headlight height values of the 11 most sold vehicles (by far compared to the 12th one) in 2015 in Spain, the average is 0.731 m, ranging between 0.658 and 0.858 m. It is important as well to know the effect of the other variables on nighttime sight distance.

Headlamp regulations around the world are not homogeneous even if vehicles put on market are mostly the same. For example, the American standard (ANSI, 2010) is compulsory in the United States and allowed in Canada and Mexico, while the European counterparts (ECE, 1995) required or allowed in most every other country in the world. Whereas European standards are more concerned about headlight glare avoidance with lower beam, which may penalize lighting performance, American standards encourage high headlight performance, at the expense of other users' visual comfort.

An additional issue in nighttime driving is headlight glare. McLaughlin et al. (2005) evaluated discomfort glare experienced by drivers at night. Glare avoidance is primarily considered by standards and automobile manufacturers. In order to reduce the chances of headlight glare, successive regulations diminished the illuminance permitted above the plane defined by the beam axes for the inner headlamp (Gibbons et al., 2012). Current headlamps provide less illuminance above that plane. Thus Hawkins and Gogula (2008) proposed to reduce the upward divergence angle considered for headlight sight distance estimation from 1 degree to a value between 0.75 and 0.9 degrees.

According to the American Federal Motor Vehicle Safety Standards (1991), headlights may be located at a height between 560 mm and 1370 mm. Likewise, the European standard (ECE, 1995) sets the minimum and maximum height at 500 mm and 1200 mm respectively. In line with this, the Italian standard (Ministero delle Intrastrutture, 2001) sets the headlight height at 0.5 m. However, parameters in highway design guides are usually based on outdated vehicle dimensions. Hence Fitzpatrick et al. (1998) characterized modern vehicle headlight heights for their use in geometric design.

The distance to the farthest point covered by light beam depends upon several factors. The first consideration concerns low beam and high beam. Also, the amount of light to consider a point as lit is essential. This implies the analysis of a more complex problem dealing with human vision and perception, affecting as well other two parameters whose influence are hereby analyzed: horizontal spread angle and upward divergence angle. Although many values may be proposed, in general, a range of 70 to 90 m assuming 3 lx as threshold illuminance for low beam could be considered headlamps according to lighting patterns (Boyce, 2009).

Fig. 1 shows the headlights geometric variables and the layout of vehicle headlights in relation to the driver position. The beam axle is parallel to the roadway grade and its heading angle equals that of the vehicle at each station. The upward divergence angle β is measured from the beam axle. The horizontal spread angle α is the angle symmetrically subtended sideward from the beam axle in both headlamps. Distances d_1, d_2 and d_3 define the location of headlamps in relation to the driver. The value d_1 is determined by the distance between the horizontal projection of the driver's eye and the projection of the straight line joining both headlamps. The d_2 is the distance between headlamps and d_3 outlines the lateral offset of the left headlamp relative to the driver, assuming right-hand traffic.

3. Materials and methods

The GIS-based application Road sight distance was utilized to compute the available sight distance (Castro et al., 2014). It has a specific module for nighttime sight distance computation. The algorithm launches lines of sight along a set of stations placed on the driver's path on the highway, evaluating whether those stations are seen from the driver's position. The nighttime module sets a further condition: the target must lie within the light beam. Such light beam comprises the two beams produced by each headlamp which are delimited by the planes defined by the horizontal spread angle, the upward divergence angle and the headlamp range (Fig. 1).

Stations are set all along the theoretical vehicle path spaced 5 meters apart. In this study, the driver's eye height and the target height were set at 1.1 and 0.5 m respectively, in conformity with the Spanish geometric design standard (Ministerio de Fomento, 2016). Likewise, the stations where driver is placed are at an offset of 1.5 m from the outer edge of lane. The beam axle is assumed to be parallel to the gradient of the vehicle travelling on the pavement all the way, which was retrieved from the vertical alignment of the highway. The slope between two successive stations can be taken from the terrain model on the roadway as surrogate value if it is precise enough. Distances d_1, d_2 and d_3 shown in Fig.1 were taken from the average values of the 11 most sold vehicles in Spain: 1.775 m, 1.345 m and 0.32 m respectively.

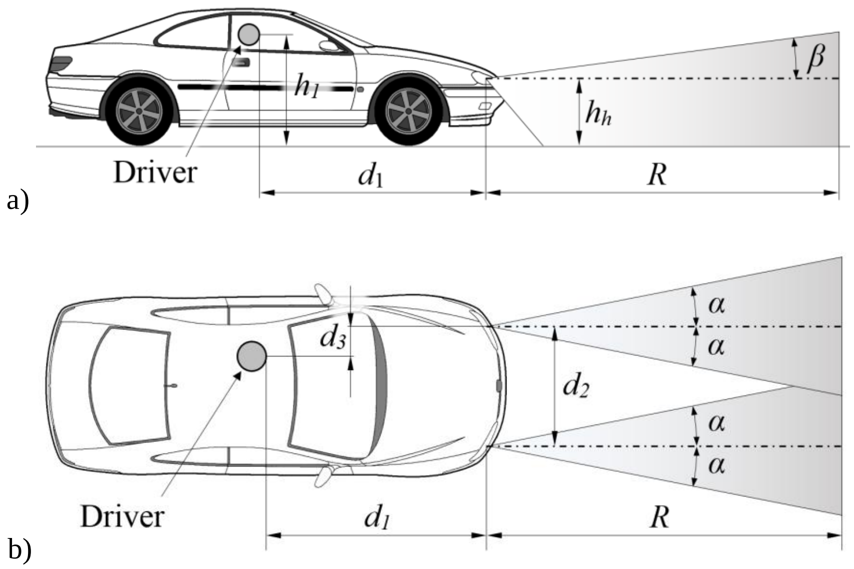

Fig. 1.
Headlamps position in relation to the driver and headlight parameters: a) profile; and b) horizontal projection

The four headlamp parameters to be studied were beam range, headlamp height, beam upward divergence and horizontal spread angle. All values considered in this study for each vehicle headlight parameter are shown in Table 1 which were taken in consistency with the above review of standards and current values. Thus, a total of 900 sets of nighttime sight distance were produced.

Table 1
Headlamp parameters and values studied

Parameters	Values
Beam range	80 m / 100 m / 150 m / 200 m / 300 m
Headlamp height	0.65 m / 0.70 m / 0.75 m / 0.80 m / 0.85 m / 0.90 m
Beam upward divergence	0.7º / 0.8º / 0.9º / 1º / 1.1º
Beam horizontal spread angle	2.5º / 3º / 3.5º / 4º / 4.5º / 5º

A two-lane rural highway was chosen for this study (M-104), which is located in the Region of Madrid (Spain). The length of the section spans 11 km. Its alignment is winding on both the horizontal and the vertical projection, and the design speed is assumed to be 60 km/h. The cross section comprises the roadway of 6.5-meter wide, and 1.25-meter hard shoulder on either side. According to the Spanish geometric design standard (Ministerio de Fomento, 2016), the corresponding stopping sight distance would be 70 m on flat grades. However, the steepest grade reaches 8% on few segments, which means that the stopping sight distance would range from 63 m, when driving uphill, to 79 m, while grade is downhill. The minimum beam range in Table 1 was chosen after this.

4. Results and discussion

First, the consistency of results was analyzed. According to what can be expected, the higher the parameter value is, the longer the nighttime sight distance results for all parameters. Moreover, performing a paired comparison between cases, where all variables remain the same except one, the median results equal or higher in the sample where the variable modified takes a higher value, whatever the variable considered is.
The Wilcoxon signed-rank test for paired samples was performed to determine whether daytime available sight distance and nighttime sight distance come from the same distribution. In all nighttime sets, the p-value resulted less than 0.0001 when compared to the daytime counterparts. It can therefore be rejected at the 99% confidence interval that nighttime sight distance and daytime available sight distance come from the same distribution. The same test was carried out between three relevant headlights cases simulated. Such datasets are those produced by the most favorable parameters (highest input values) , the standard values (beam range 200 m, headlight height 0.75 m, upward divergence 1 degree and horizontal spread 3 degrees), and the most unfavorable parameters (lowest input values). The cumulative frequency graph of these results can also be seen on Fig.2. Even in these cases, the p-value resulted also less than 0.001. Consequently, it can therefore be rejected at the 99% confidence interval that any of these four datasets come from the same distribution.

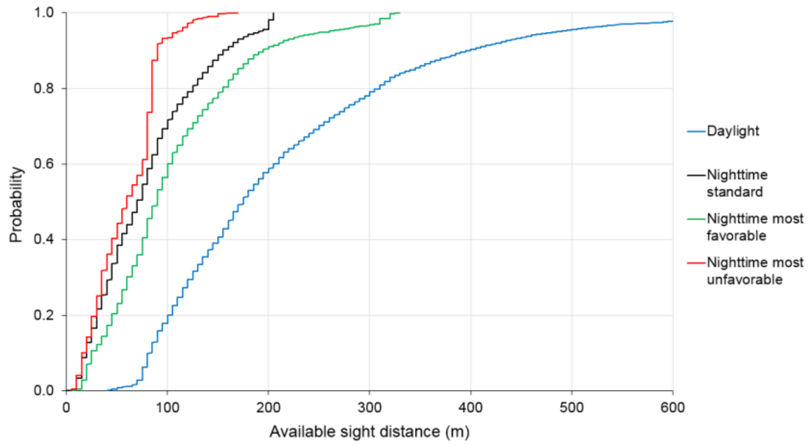

Fig. 2.
Cumulative frequency graph of four relevant available sight distance datasets

It has to be borne in mind that the available sight distance is measured along the vehicle trajectory on the roadway. Conversely, the headlamp range is a straight-line distance. This means that on a winding stretch, the available sight distance outcome may exceed the nominal headlamp range. This fact can be noticed on Fig. 2, where the beam range for nighttime sight distance of the most unfavorable case is 80 m and values over that threshold arose. The same applies to nighttime sight distance in the standard case (beam range: 200 m) and most favorable (beam range: 300 m).
The reader must keep in mind that the lighting range provides the driver with information, among others of the alignment, traffic signs and possible obstacles on the roadway. Notwithstanding the foregoing, the daytime sight distance is still useful in nighttime driving since the field of vision allowed by the roadway and roadside features enable the driver to see other users' headlights and taillights, especially with regard to passing sight distance.
To study the influence of the headlamp range, three series of headlight datasets results were considered, where all parameters are fixed except the beam range. Once again, the first series of results corresponds to the maximum of those values studied (most favorable), the second one set fixes the values at their standard values (headlight height 0.75 m, upward divergence 1 degree and horizontal spread 3 degrees) and the last one takes the most unfavorable ones (minimum values). Fig. 3 shows the share of the overall length where the available sight distance is limited by the headlamp range. While the three series take similar values and show a sharp decrease of sight distance limited for the shortest ranges, the standard and the most unfavorable series present a very low decrease at the highest range around 82 and 85% respectively. Only the most favorable series continues reducing the limitation of the light beam at a moderate rate below 75%. This fact would prove that the rest of parameters are those which enhance visibility conditions to create the evident gap between the most favorable series and the two others. However, if sections with limited sight distance (below values recommended by Spanish standard) are considered exclusively, the influence of headlamp range is null since range is assumed to be no shorter than 80 m.
It is also remarkable that in the case of the winding highway considered in this study, even in the best case, the nighttime sight distance is limited by the light beam along three quarters of the track. Although the geometric design of the highway determines indeed how much of the section ahead is illuminated, it is not the only restrictive factor. It would be interesting to test different roadway scenarios with diverse clearances to study the influence of alignment and roadsides.

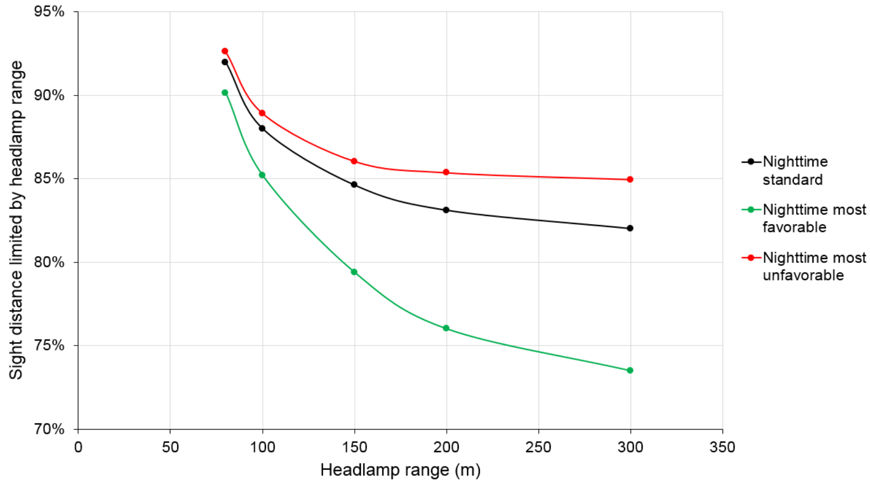

Fig. 3.
Share of nighttime sight distance limited by headlamp range

Next, the influence of headlight height was studied. Likewise, three series of datasets were considered. On each, all the headlight height are considered for the most favorable (maximum values for the other parameters), the standard and the most unfavorable (maximum values for the other parameters). The median of each dataset and the percentage below the available sight distance enforced by the Spanish standard (79 m) were studied to evaluate the influence of this parameter. The median is considered instead of the mean value since the sight distance take discrete values. The consideration of the share of sight distance above the standards permits the study of the influence of this parameter in the lowest tail of the samples, i.e. the zones where the hazard is higher. The results shown in Fig. 4 indicate that this influence is low regardless of the series considered. While the share of sight distance above the stopping sight distance rises slowly, the median values jump just one step (5 meters) in the most favorable and most unfavorable series.

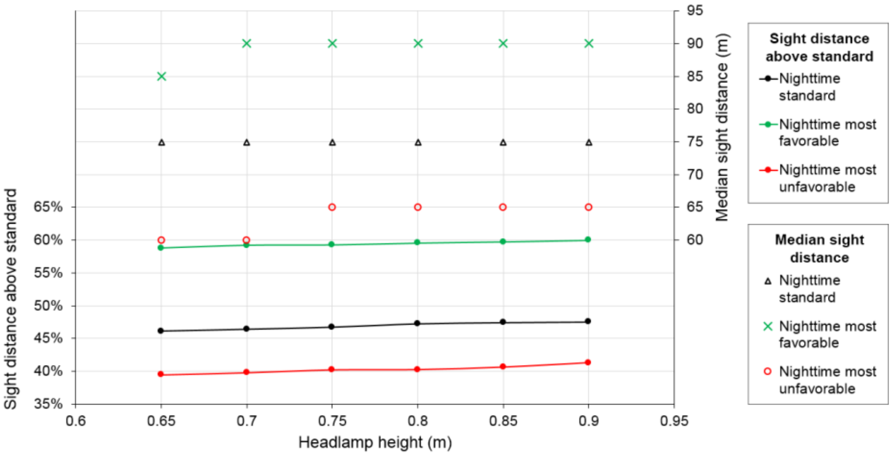

Fig. 4.
Influence of headlamp height on the share of nighttime sight distance above stopping sight distance and median nighttime sight distance

The analysis that follows corresponds to the influence of the beam horizontal spread angle. The usual three series of datasets were considered, varying the value of the horizontal spread angle: the most favorable combination of the parameters, the other standard parameters and the most unfavorable combination of them. The influence of the horizontal angle is significantly higher than in the case of the headlight height because it increases steadily on the three series of data, at a rate of around 5% per degree (Fig. 5). Also, almost every increment of the spread angle entails an increment on the sight distance median. However, the enhancement of the visual field at night as the horizontal spread angle increases is counteracted in terms of safety by the possibility of producing glare to other road users.
Finally, the influence of the upward divergence angle is addressed. As for the previous parameters, the usual three series of datasets were considered while the vertical angle above the beam axle is varied: most favorable, standard and most unfavorable. The results are shown in Fig. 6. Firstly, the variation of the share of sight distance above standard is less close to be linear since a discontinuity around 0.9 degrees is observed for the three series. While the improvement in results is noticeable as the upward divergence changes from 0.8 to 0.9 degrees, it is barely perceptible when the angle is increased to 1 degree. Although the range of the upward divergence at stake is smaller than that of the horizontal spread, the influence of the vertical one is greater per degree. The divergence angle above the beam axle is also hazardous with regard to headlight glare.

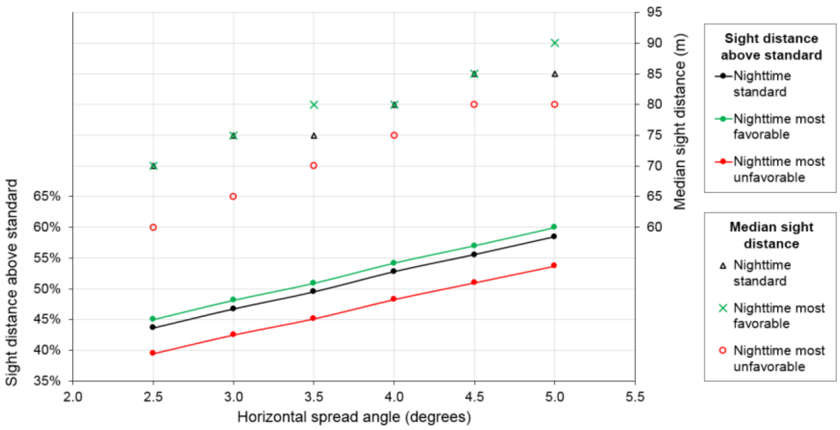

Fig. 5.
Influence of beam horizontal spread angle on the share of nighttime sight distance above stopping sight distance and median nighttime sight distance

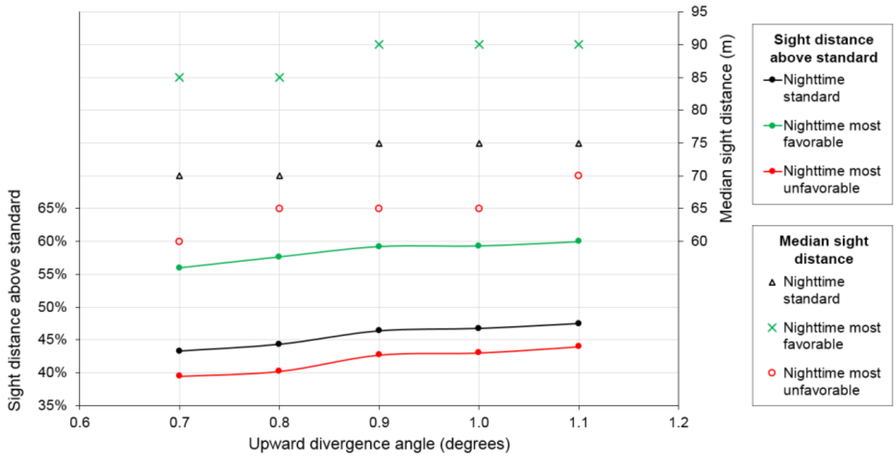

Fig. 6.
Influence of beam upward divergence angle on the share of nighttime sight distance above stopping sight distance and median nighttime sight distance

5. Conclusions

The influence of four vehicle headlight parameters has been studied: headlamp height, beam range, horizontal spread and upward divergence angle. This methodology also sets the basis of nighttime sight distance on driving safety research.

The expected qualitative effect of each parameter was produced in the results, i.e. the nighttime sight distance increased as the parameter values did so. However, the numerical influence of each one was different. It was found that the most influencing parameter was the upward divergence angle, particularly when sight distance are below those recommended by guides. In this case study, the results show that an angle of 0.9 degrees produces nighttime visibility conditions as satisfactory as for the widespread standard value of 1 degree. Also, the influence of the horizontal spread angle is close in importance to the vertical angle above the beam axle. The beam range is nonetheless useful for little in the case of a winding highway such as the case herein addressed.

Although the Spanish standard takes a relatively high headlamp height to study nighttime sight distance, especially when compared to the American one, the results evidenced that the influence of this parameter is very little and the dependences seem much greater for the other parameters. It can be concluded from this that the safety implications of this assumption are not significant. In further studies, the effect of directional headlights on nighttime sight distance is to be analyzed. In addition, different scenarios may be set up in order to test how effective this novel technique results depending on the clearance available in curves.

ACCESSIBLE BOARDING FOR RAIL PASSENGERS

Bernhard Rüger[1], Goran Simić[2]
[1] *Vienna University of Technology, Vienna, Austria*
[2] *Belgrade University of Belgrade, Belgrade, Serbia*

Abstract: Regarding to EU regulations today's public transportation systems must be accessible for everyone without any restrictions. The relevant question is: How can trains be accessible for everyone? The huge variety of different vehicles and different platforms does not allow level boarding everywhere, only in so called "closed" systems. The paper gives an overview about the requirements for new boarding assistance systems and about the decision making process referring to a new developed lift system for UIC-coaches. This lift system is developed in the EU-founded project PubTrans4All.

Keywords: accessibility, vehicle entrance, boarding assistance device, PRM.

1. Introduction

The result of the previous work in the PubTrans4All-project, founded by the EU, led to the decision that the most important step towards an accessible rail system at the moment is the development of a boarding assistance system (BAS) for existing UIC wagons. These cars are still in use in large number all over Europe. Due to design limitations it is not possible to retrofit these types of vehicles in order to use existing BAS. So at the moment only platform based BAS can be used for wheel chair users. For all other types of vehicles some kind of BAS exists (lifts for high speed trains, ramps for low floor trains). The aim of further research in this project was to develop a BAS that can be used for installation in UIC wagons.
The layout of older UIC coaches and modern high speed trains that are designed for wheelchair users and other PRMs in general is similar. UIC coaches has small doors with a width of 800, while in modern trains the door width is increased to 900mm. The difference is that there are already lift solutions for a door width of 900mm but none for narrower doors. The UIC coach has doors located at the end of the coaches. Because of the folding or sliding steps as vicinity of the buffers as well as other constraints, there is no space under the steps for the installation of a BAS. Additionally, the space at the coach end is occupied by mechanisms of the head doors leading to the next coach, fire fighting equipment, some electrical components etc. Typical for these coaches is that the passageway is in majority cases at one side outside the longitudinal centre line of the vehicle because of the neighbouring toilet cabins adapted for people with handicaps and persons with reduced mobility. Finally, there are usually only two potential positions left which could be used for stowing the BAS.

2. General requirements for a new boarding assistance system

The general requirements provide an overview of all relevant parameters that must be considered when designing a new boarding assistance system. Table 1 presents the importance scores used in order to rank the evaluation criteria. Table 2a/b summarizes the requirements. Features rated as not important, are not shown herein.

Table 1
Criteria importance scoring

Score	Meaning
1	Very important – critical to successful operation ("must have")
2	Important – high benefit for users and operators ("nice to have")
3	Less important – some benefit for users and operators, but not absolutely necessary

Table 2a
BAS evaluation criteria - overview

User with devices	Wheelchair, walking frame, baby prams	1-2
Physical impaired	Walking disabled, with crutch or sticks, elderly, diminutive people	2
User with special needs	Visual and hearing impaired	2-3
General passengers	Passengers with luggage, children, pregnant	2-3
Operation without staff	Operation by passengers themselves, automation	2

Table 2b
BAS evaluation criteria - overview

Operator		
Reliability of BAS	Prevention of Malfunction	1
Operational quality	Short dwell time, malfunctions must not influence train operations	1-2
Operational effort	Number of staff	1-2
Failure management	Problems easy to solve	1
Manufacturing/ Implementation		
Universalism	The system needs to be universal, retro-fitting allowed	1-2
Costs	Costs as low as possible	1
Manufacturing effort	The manufacturing effort needs to be low – especially when retro-fitting	1-2
Safety		
Safety risks	No safety risks to be tolerated	1
Safety features	Optical and audio signals	1-2
Maintenance		
Maintenance effort	Number of personnel required, special tool required	1
Costs		2
Sustainability	Recyclability and energy consumption	3
Aesthetics		
Optical design	Aesthetics is important for customer acceptance	2-3
All regulations must be fulfilled (currently according to TSI-PRM) as a minimum standard. Some specifications in project PT4All have been set higher than required.		

3. Decision making process

At the beginning of the project the consortium consciously set the bar very high in order to get the best possible results. The primary defined goal of the project was to find a technical solution to provide accessibility to all passengers in all boarding situations. To get innovative and completely new ideas, a student competition was also initiated. The consortium believed that students don't have the detailed knowledge about railway vehicles and they are therefore more independent in their thoughts. Experts usually have a tunnel vision because they think too much about reasons why something cannot work.

After a long research and discussion process including the excellent ideas from the competition, the consortium concluded that many restrictions are necessary and the all-in-one solution is not possible. At this point it must not be forgotten that the PubTrans4All project is a research project which also has the goal of demonstrating what is and is not possible.

In the first step, current and future plans of the different railway systems over the whole of Europe have been analyzed in order to identify the biggest gaps.

For all local systems (including busses, tramways, metros, urban and suburban railway traffic) a newly developed BAS is neither necessary nor meaningful. All these systems can be seen as so called "closed systems". Here the operators provide vehicles which correspond to the existing platform height; which means level boarding is provided. If level boarding is not yet provided, then operators plan to adapt the platforms and/or their vehicles. Local traffic operators in general don't want to use technical devices (BAS) because of operational time reasons.

Level boarding is in general the best solution for travelers and for operators. It is the only situation which really offers accessibility to all passengers. Furthermore, the passenger flow in the station can be speeded up which means a shorter dwell time and therefore advantages for operators.

To offer level boarding it is necessary that the platform and the vehicle floor have a common height and the remaining horizontal gap between vehicle and platform is bridged. For that many technical solutions already exist.

For all situations where level boarding is not possible, different approved technical solutions such as ramps or lifts already exist.

Compared to the local traffic systems; high speed, long distance and international railway traffic will not be able to offer level boarding for the following two reasons: The first reason is that because of static, high speed trains need a higher floor. The lowest floor height in high speed trains is offered in Talgo-trains (760mm). All other vehicles have got higher floor height.

The second reason is that in the TSI two different platform heights are defined as European standard (550mm and 760mm). That also means for the next decades all international trains will need to stop at both levels!

Furthermore, the investigation has also shown that actually within the next decades a huge number of high floor vehicles will run in European countries in long distance traffic. Due to the long life cycle of railway vehicles they can't be changed in a short or medium term.

So the decision was to develop a BAS for all types of high floor vehicles. In general there are four possibilities – ramps or lifts, platform or vehicle based.

The operators' surveys clearly show that operators either plan to provide level boarding in the future or – everywhere they cannot – they strongly wish to have vehicle based systems. Two reasons can be identified for that wish: Firstly, operators want to be independent from the infrastructure and want to offer the possibility of accessible boarding everywhere. Secondly, it is very difficult to provide a platform based device at all (!) platforms in a railway network.
In order to provide accessibility to all passengers, ramps seem to be the only possibility because lifts cause a big bottle neck if every passenger tries to use one door. But here the big problem is that it was not possible to find a technical solution for installing a ramp system into existing vehicles. Furthermore, ramps must be very long if they will be used for high floor vehicles.
Because of the impossibility of finding any technical solution for ramps in existing high floor vehicles, the decision was to focus on lift systems for existing high floor vehicles. For the next steps of development two decisions have been necessary: Who the user will be and which vehicles are relevant.
The investigations show that for all types of high floor trains with an entrance door width of at least 90cm, different lift systems already exist. It is not meaningful to develop another system because passenger and operator surveys have shown that the existing systems work well enough.
But there is one very big group of high floor railway vehicles in Europe, the so called UIC-wagons. This is a unique type of vehicle which will be running in many European countries for some decades more. In many countries the UIC-wagons form the backbone of the long distance railway traffic, especially in eastern European countries. But due to many construction limitations described in previous deliverables no technical solution has yet been developed. Therefore, the consortium came to the decision that the most important step to offer accessibility to all is to focus on UIC-coaches!
A lift system under very limited frame condition means many restrictions and compromises. In regard to user requirements, wheelchair users are the only passengers for whom a technical solution is an absolute must. For many other groups it would be very nice to have some technical devices; but if there is no chance, than other solutions are acceptable. As other solutions, special services at the entrance door are recommended within this project. There already exist good examples in different European countries which can be advanced.
At the end of the decision process, it came out that the most important case is to develop a vehicle based BAS for UIC-coaches. Since there are many restrictions because of the vehicle design, it has also for this situation been necessary to define some "compromise solutions" regarding the construction. All recommendations for a vehicle based BAS for UIC-coaches are shown in the next chapter "Detailed technical requirements for a BAS for UIC wagons".

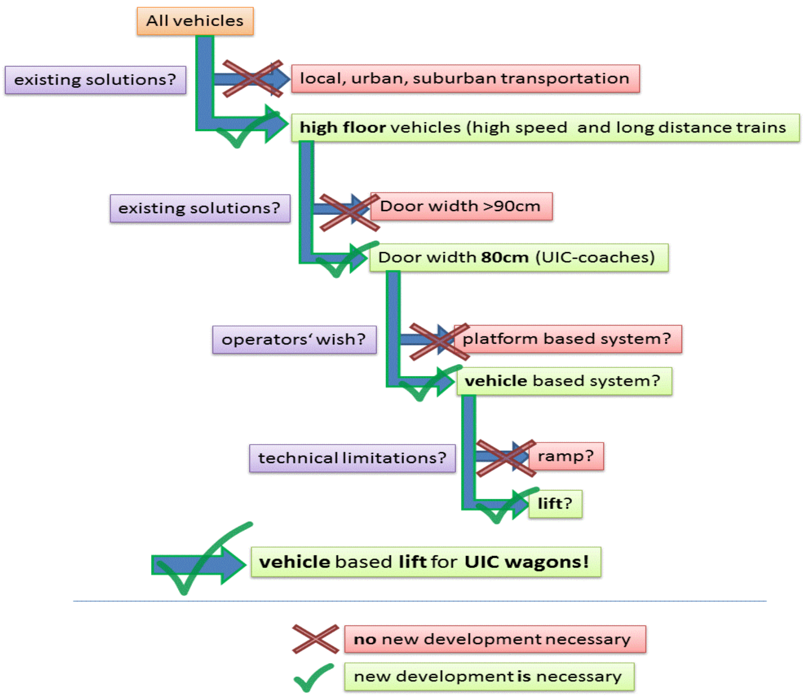

Fig. 1.
Decision making process

4. Technical requirements for a BAS for UIC wagons

As described in the chapter "decision making process" the consortium decided to focus on a BAS that can be implemented into UIC wagons. Therefore, at this point all technical requirements that have been identified especially for the implementation into UIC wagons will be described in detail.

Table 3a
Applicability of a BAS in different vehicles

Characteristic	Value	Comment
Carrying capacity	300kg	Covers 99% of wheelchair users
Minimum clear width of lift platform	720mm	Covers 96% of wheelchair users
Minimum platform length	1200mm	
Maximum working height difference vehicle floor-platform	1300mm	
Distance from the side of the coach when the lift platform is in lowered position:	as small as possible, but not less than 75 mm	The lowest foldable stair required to be lifted up before descending of the lift platform.
Boarding/alighting parallel to the vehicle	recommended	Alternatively, exit sideways through lay down of the side fenders (required for narrow platforms)
Handrail bound to the platform on one side, should be at the height of	650 to 1100mm from platform level	
Integrated folding seat for categories of users other than wheelchair users	recommended	
Finger pressure for activation of control buttons	≤ 5N	
Manual force to operate the lift by staff	≤ 200N	For example for emergency mechanical activation.
Manual force to operate the lift by staff at movement start	≤ 250N	Allowed only for short period at the start. For example for emergency mechanical activation.
Vertical speed in the operation	≤ 0.15 m/s	Movement should be smooth
Operating speed variation: empty-maximum loaded	±10%	
Speed of any point of BAS without load	≤ 0.2 m/s	Up to 0,6m/s is allowed by EN 1756-2. To meet TSI PRM, maximum speed without load no more than 0,3m/s is recommended.
Acceleration during operation with load in any direction and at any point of the lift platform	≤0.3 g	
Tilting speed of the lift platform	≤ 4o/s	In case of automatic adaptation to the relative angle between vehicle and platform, for example at superelevated track by platforms in curves.
Automatic roll-off protection height	≥100mm	The barrier in front and at rear side of the wheelchair lift platform should be automatically erected during lift operation.
Lateral side guards height:	≥25mm min ≥50mm preferred	Prevention of the wheelchair side roll-off from the lift platform
End of travel mechanical limitation devices	yes	
Prevention of any unauthorized operation in the absence of the operator	yes	Locking and unlocking by a key or a code or similar.
Overload protection of the main power electrical circuit		Fuse, an overload cut-out or similar
In stowed position BAS must be safe against uncontrolled displacements. Mechanical securing devices dimensioning according to the accelerations:	alongitudinal=5g alateral=1.5g avertical=1g	These accelerations can arise in the exceptional case of occasionally buffing impact at coach staying in yard (without passenger) (UIC 566)

Table 3b
Applicability of a BAS in different vehicles

Characteristic	Value	Comment
Activation possible only at:	V = 0 km/h.	
Activation of the BAS should introduce activation of the coach brake system.	yes	Movement of the train during BAS usage must be prevented
Minimum safety coefficient against yield strength	2.1	
The lift platform surface should be smooth and must have slip-resistant surface	yes	Slip resistance according to EN ISO 14122-2.
Easy removal of ice and snow must be possible	yes	
Gaps or holes in the platform area shall not accept a probe greater than:	15 mm diameter	
Illumination of the lift working zone	yes	
The warning devices should be fitted at edges that can come in contact with persons or injure passengers or personal.	yes	light / reflective stripes / reflective markings, visible at night also
Visual and audible warning signals during the lift movement must be activated	yes	
The operation control should be of type hold-to-run.	yes	Lift shall stop moving and remain motionless after the control is released.
Movement no more than 100mm for any part of the lift platform after release of the control is tolerable to slow lift down	yes	Mechanical drives with self-braking capability or with independent direct acting brakes, or hydraulic systems with normally closed valves etc. should be used.
Controls shall be designed to avoid unintentional lift actions.	yes	Recessed or covered buttons, two hand controls, etc.
One control position is recommended	yes	Conflicts of commands must be avoided
In any case of breakdown, it is acceptable that platform may decrease with controlled speed:	≤ 0,165 m / s	For example in hose or pipe failure by hydraulic systems or similar.
Safety devices shall preferably operate through active positive action.	yes	
A stop in overload protection should be present at overload more than	25%	
An emergency stop button within reach of the user should be present	yes	Release of the emergency stop button should only be possible by the personnel
Additional protecting measures such as obstacle detector, foot entrapment protection etc.	recommended	Although control of hold-to-run principle is used additional measures are recommended
During lift platform closing the risks of crushing or shearing of the arms or head must be avoided.	yes	Limitation of the closing force, security cut-off, etc.
Other technical details not covered in this table preferably should be based on:	TSI PRM, EN 1756-2, RVAR	

5. Outlook - Conclusions

Providing accessible rail transport to all passengers is nowadays a must. This is because of different national and European regulations but also because of ethical questions. That means every person must be able to use a public means of transportation. In light of this, the entrance to railway vehicles and the whole boarding process is a big challenge and causes huge difficulties.

In order to be able to provide accessible boarding to all passengers, the consortium tried to define the biggest gaps that must be closed.

For mid and long term thinking the results can be summarized as follows: Because level boarding is in the process of being or will be offered soon for all types of local, urban and suburban traffic; no systems are required. At this point, only horizontal gaps need to be bridged. Therefore, enough technical solutions already exist. In the rare case that level boarding is not possible, existing technical solutions can be used.

For all high floor vehicles with an entrance door width of at least 90cm, enough technical solutions such as different lifts exist. A new development is neither meaningful nor necessary.

The intensive investigations of the consortium led to the result that for the huge number of UIC-wagons which are running and will be running within the next decades all over Europe no vehicle based BAS yet exists. There are too many design limitations.

Due to the fact that UIC-wagons will still form the backbone in many European railway networks within the next decades; it is absolutely necessary to develop a BAS for this operation.

Due to the different limitations resulting from the vehicle construction, it is also necessary to make several compromises. But the developed compromise allows about 99% of all actual wheel chair users to board a UIC-coach. In combination with a good personnel service at the entrance, which is also recommended in this project, the UIC wagons can also become accessible for nearly all passengers.

EFFICIENT RAIL INTERIORS - TYPICAL DESIGN ERRORS AND POSSIBILITIES FOR IMPROVEMENT

Bernhard Rüger[1]
[1] *Vienna University of Technology, Vienna, Austria*

Abstract: In order to be "competitive" as a railway, operating efficiency counts as an important imperative. In the context of railway carriage interior planning this is often made subordinate to other substantial aspects such as for example, expediency. This leads in practice to the opposite wished for result. Misunderstood operating efficiency concepts such as a maximal utilization of space for seating can in reality lead to a decline in operating efficiency, operational problems and in incidents to serious safety risks.

Keywords: passenger comfort, needs, expectations, passenger flow, utilization rate, optimization.

1. Introduction

The railway finds itself, especially in long-distance travel, in an area of tension between both of its competitors, road travel and air travel. People who travel by air have or at least see no alternative to air travel. This leads to an acceptance by air travellers of comfort constraints which arise due to economic pressures on the airlines. Airlines can afford to arrange the seats in the passenger cabin to achieve a maximum of seating. Since in airline travel reservations as well as the check-in of luggage are compulsory, all seats can therefore actually be used and sold.
For the railway such restrictions or drastic loss of comfort are not common and are therefore seldom implemented. Depending on travel duration and distance at least half of railway passengers could use the alternative of auto or air travel. Over 50% of travellers on ÖBB long-distance trains say that they have a driving license and have an auto available at any time. Also, because airline tickets are to some extent inexpensive, the cost argument regarding this mode of transportation is often eliminated. This in turn makes air travel more attractive.
The railway cannot afford to (and should not) ignore the demands and needs of travellers. In order to achieve the high proportion of railway travellers wished for in transport policy, which as a rule also actually contains economic benefits, the railway must bring into play the advantages which it has over other modes of transportation.
However, the tendency in recent years to equip vehicle interiors with the highest possible number of seats contradicts these considerations. This leads not only to a loss of comfort, which approximates the comfort level of air travel, but also in a number of ways constitutes serious operational problems. These problems are often not considered especially in the purchase of vehicles. The often applied evaluation criterion of the highest possible number of seats and thereby expected lower purchase- and operating costs per passenger is one-dimensional and therefore inadequate since it clearly contradicts reality in more ways than one. The consequences are elucidated in this paper.
Especially in long-distance train travel but also on many local routes particularly in the service of cruise ship ports and airports the volume of luggage is often underestimated and not taken seriously in sufficient measure as an influence factor on the criteria of station dwell time, achievable seat occupancy rate, comfort, customer satisfaction and ultimately safety.

2. Data basis

For nearly 15 years The Research Centre for Railway Engineering at the Technical University of Vienna has been intensively involved in cooperation with netwiss OG with questions on a scientific level related to the optimization potential of railway carriages. The core of all research and development projects as well as the resulting scientific work is the serious examination of the needs and wishes of travellers as well as with their problems and difficulties in using the train. A substantial contribution to the objectification of the findings is the data collected over a decade concerning passenger behaviour, which has been and will continue to be collected through observation. The goal thereby is to capture the real behaviour of passengers under different marginal conditions uninfluenced by possible personal sentiments which may affect the results of surveys. Surveys formed an additional basis for the scientific analysis.
Thus far, over ten years, data has been collected on the following areas:

- **Passenger flow analysis:** The boarding and deboarding of approx. 20,000 passengers in approx. 50 different boarding areas and vehicle types were observed. Through video analysis precisely to a tenth of a second it was ascertained how long on average a person needs for boarding and deboarding. Above all, in addition to knowledge about individual time requirements, crucial insight can be gained into the extent to which the entire vehicle design concept affects passenger flow,
- **Passenger surveys:** Approximately 40,000 passengers in just under 10 different countries were surveyed concerning their problems and difficulties as well as their needs and wishes in all phases of travel in a railway vehicle. This related to boarding as well as movement in the train, the search for seating, stowing of luggage and requirements during the trip itself.

[1] Corresponding author: bernhard.rueger@tuwien.ac.at

- **Passenger behaviour analyses:** The behaviour of approx. 200,000 passengers in more than 60 different vehicle types was analyzed with regard to choice of seats, storage of luggage and use of time. From the data, depending on the parameters of age, gender, occupancy rate in the vehicle and space design, information was accurately derived concerning which seats or seating areas were preferred, how and where luggage was stowed as well as the activities passengers performed,
- **Luggage data collection:** In combination with surveys, the exact anticipated luggage types and volumes per person, per vehicle or per train depending on travel purpose, age and gender as well as group size was determined through counting, exact measurements and weighing of several thousand pieces of luggage.

In terms of new vehicle design concepts the data provides exact conclusions on how the envisaged space design will be used, how the design will affect passenger behaviour regarding seat selection, storing of luggage and performance of activities, and what impact the behaviour will ultimately have on the parameters of passenger boarding and deboarding, proper stowage of luggage and actually achievable seat occupancy.

3. Luggage volume

Type, size, weight and number of particular pieces of luggage depend substantially on the parameters of travel purpose in combination with travel duration, age, gender and present group size of the travellers.
More than ten years of intensive observation shows that the volumes of individual pieces of luggage tend to be larger. This is due to an increase in comfort during transport particularly attributable to the fitting of luggage with rollers. For example, pieces of luggage which weigh 14 kilos and are meant to be carried feel as though they are the same weight as pieces of luggage which weigh 21 kilos but are equipped with two rollers. Fifteen years ago 50% of suitcases taken along on rail travel were not equipped with rollers and therefore had to be carried. Five years ago this percentage amounted to about 5%. In the meantime, nearly 100% of suitcases, so-called trolleys, are equipped with rollers.
In accordance with the comfort enhancement provided by rollers increasingly larger pieces of luggage are being manufactured and used by travellers. This has led not only to an increase in the size of individual pieces of luggage but also to an increase in weight. Meanwhile, the tendency can be seen in luggage manufacturers to equip more and more trolleys with four wheels. As a result, in many transport situations an additional increase in comfort has been achieved. The assumption is that these pieces of luggage will be felt to be even more comfortable and in weight comparison even lighter; therefore, in the near future a further increase in luggage volume and pack weight is to be expected.
Both the increase in weight as well as in size present the rail operator with corresponding challenges. Namely, in the case of boarding the train over steps as well as the frequently necessary lifting of luggage in stowing, the rollers provide no support and accordingly increase the difficulties for travellers.
The next figure presents the average luggage distribution per travel purpose (Plank, 2008).

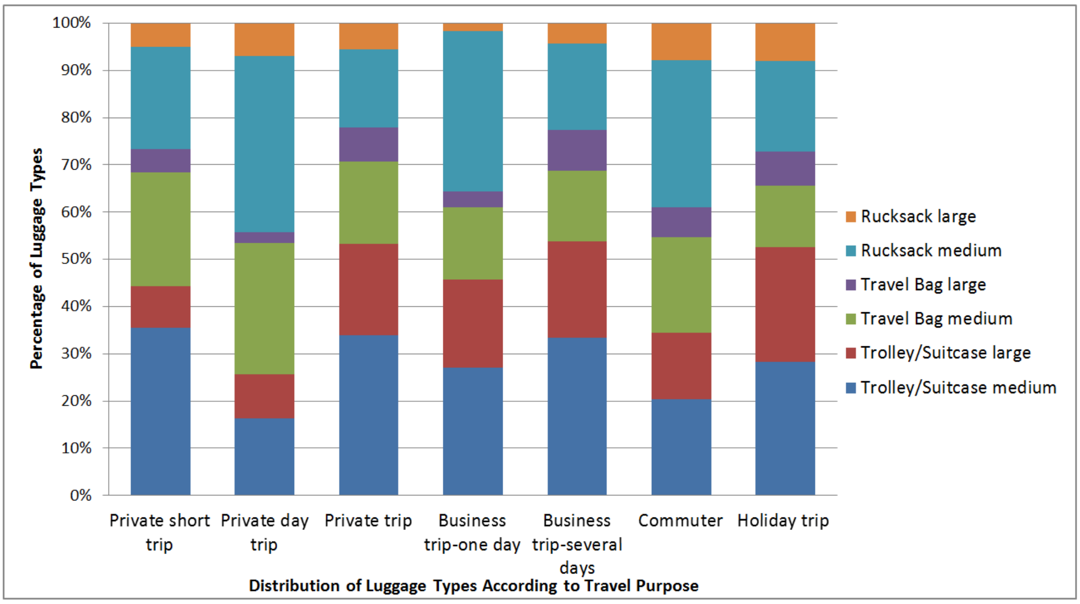

Fig. 1.
Average Luggage Distribution per Travel Purpose

In order to construct adequate and efficient luggage storage areas, as a first step, knowledge of luggage volume in terms of type, size, weight and number of pieces per person is important. With regard to an efficient overall interior design statements on this cannot and must not be generalized. It appears that there can also be a regionally specific difference in the accompanying luggage. In particular the total volume to be reckoned with for each carriage is highly dependent

on respective routes and their passenger or travel purpose mix. However, due to the existing amount of data very specific remarks can be made about this.
For example, in holiday travel on statistical average 50% of travel luggage pieces are medium and large trolleys (see Figure 1). At the same time it can be said that on average one piece of luggage per person is taken on holiday. On short trips on statistical average each traveller takes 0.8 pieces of luggage which are 35% medium and 10% large trolleys (see Figure 2). Relevant to necessary luggage accommodation is the most exact knowledge possible of the travel purpose mix which particular vehicles in their area of operation can expect. From this the actual expected average luggage volume per person and thus the corresponding total volume per vehicle can be determined.
The next figure presents the average luggage number per person and per travel purpose (Plank, 2008).

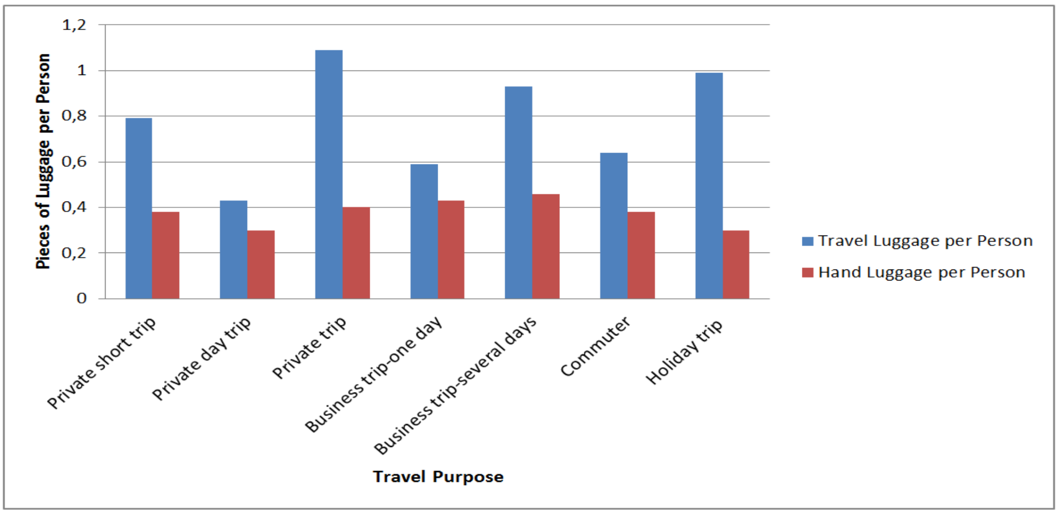

Fig. 2.
Average Luggage Number per Person per Travel Purpose

For air travellers who use the train for arrival an approx. 20% higher luggage volume is shown than for plain holiday train travel. This fact should be taken into account especially for all trains which eventually serve airports.
As an example of luggage volume, the average travel purpose distribution in Germany was used in a fictional carriage with 84 seats and a 100% occupancy, which led to the luggage volume represented in table 1.
The next table shows an example for the luggage distribution for one wagon (Rüger et al., 2010).

Table 1
Fictional Example: Luggage volume for an average travel purpose distribution in Germany with 84 people per carriage

Luggage type	Dimensions (cm)	Number with 84 People
Trolley large	approx. 80x50x35	13
Trolley medium	up to 70x50x30	23
Travel bag/Rucksack large	approx. 90x40x35	9
Travel bag/Rucksack medium	up to 70x35x35	29
Hand luggage	up to 55x40x25	32

On average travel days an average of 36 medium and large trolleys and 38 medium and large rucksacks or travel bags were stowed. With regard to luggage accommodation the total volume of luggage must subsequently be superimposed on the wished for or actual passenger behaviour concerning the accommodation. For example, to believe that the luggage volume can be accommodated in overhead racks is a fatal mistake. Even if the calculated luggage volume could be stored in overhead racks the majority of travellers would not use the overhead racks. This means in practice much of the luggage would be stowed disruptively (see below).

4. Luggage Accommodation

4.1. Passenger Behaviour

Regarding luggage accommodation there are two fundamental principles. Travellers do not want to have to lift their luggage; and for security reasons they want to have visual contact with their luggage at all times. If these two criteria are not sufficiently taken into account from the very beginning of planning, inefficient and in an "incident" quite dangerous conditions in the vehicles can be expected.

For 88% of passengers visual contact to their luggage is important or very important. This means that luggage must be able to be stowed in close proximity to the traveller. If there is no adequate possibility for this, and the luggage must be stowed at a greater distance, such as in luggage racks near the entrance, for most travellers this results in a corresponding uneasiness and loss of comfort. However, from an operational viewpoint the risk is even greater from luggage which due to a lack of visual contact has been stowed disruptively. Seventy-five percent of travellers indicate explicitly that they are prepared to stow their luggage disruptively in order to meet the need for visual contact.
As a result, luggage is placed on or in front of seats or in aisle areas. This leads to an increase in unusable seats and obstructions to passenger flow.
The second important criterion with regard to planning appropriate luggage racks is the willingness to lift luggage. For example, only 20% of travellers are prepared to lift heavy luggage into the overhead rack; over 50% are under no circumstances ready to do such lifting. With medium sized luggage at least 50% are prepared to lift it into the overhead rack. With regard to luggage racks, at least 50% of travellers are prepared to lift heavy luggage up to waist level (see Figure 3). These specific values make it clear that it is pointless to provide overhead racks with no exception or alternative. Also, the existing number of luggage racks must be adequately dimensioned!
The next figure presents the readiness to lift luggage (Plank, 2008).

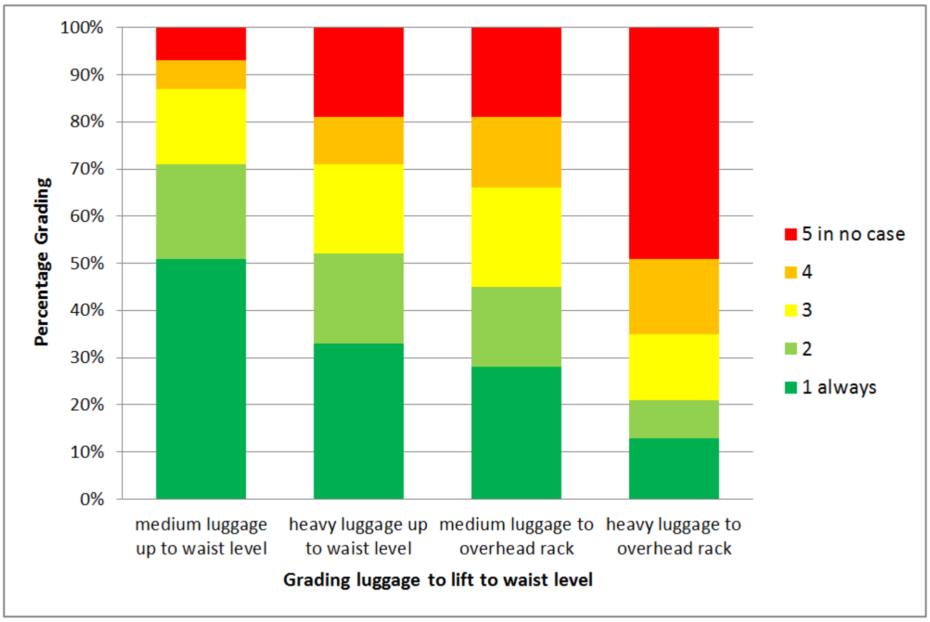

Fig. 3.
Readiness to Lift Luggage

The sampled readiness regarding luggage accommodation has been confirmed by extensive objective observations. Although in some cases up to 50% of the overhead racks are not used, a variety of pieces of luggage are placed on the floor, in front of seats, in the aisle or on seats.
At lower occupancy rates of up to 35%, thirty percent of medium and large trolleys are placed on or in front of seats or in the aisle. Even at high occupancy rates of over 70%, by which making seats free can be expected, up to 20% of large and medium sized trolleys are placed in these positions. With rucksacks and travel bags nearly the same behaviour has been observed.

4.2. Possibilities for Accommodation

The basic possibilities for luggage accommodation are: overhead racks, luggage racks and spaces between the seat backrests. In part, areas under the seats can also be used. However, as a rule these areas can be used only for those pieces of luggage which fall under the category of hand luggage.
In order to design luggage storage space so that even with a very high occupancy rate all luggage can be properly accommodated, the following principles must be observed:

- Above mentioned principles "not lifting" and "visual contact",
- Determination of the actual luggage volume,
- Reliable knowledge of the shape of the luggage.

In order to efficiently design the most popular storage spaces between the seats and in the luggage racks, knowledge of the shape, size and volume of the luggage is by all means essential. Experience shows that luggage racks which are only a few centimetres, often only 5 cm to 10 cm too narrowly dimensioned, or whose shelf heights are too high or too low, can hold up to 50% less luggage than suitably dimensioned shelves!

The same applies to the space behind or between the seat backrests. Here 10 cm to 15 cm of too little usable space can lead to 70% less storage space.
In addition to the appropriate sizing of luggage racks and seat spacing, it is also important to ensure a well considered distribution of luggage storage possibilities in the vehicle. These must be distributed as evenly as possible over the vehicle to allow good visual contact to luggage from each seat and not impair the flow of passengers.

5. Consequences of unsuitable luggage accommodation possibilities

If the important basic principles of luggage storage space design are not respected, two serious operational consequences can be expected. The passenger boarding and deboarding time in stations will be prolonged and the actual available occupancy rate will decline up to 80%.

5.1. Passenger boarding and deboarding time

There are many factors which affect passenger boarding and deboarding time. These include passenger related factors which manufacturers and operators have no control over. These factors include age, gender, accompanying luggage and any kind of mobility limitation.
However, the vehicle-side factors are important. On one hand, by correct planning the passenger-side factors can be correspondingly reduced; on the other hand, by improper planning these can be exacerbated. These factors include for example, the entry height and door width, potentially any existing level entrances, location and number of entrances, the suitability of entrance spaces as collection areas, any restrictions to passenger flow and the overall design of the vehicle interior.
From the perspective of passenger boarding and deboarding time the difference between the best and the worst vehicles currently in use is at a ratio of 1:4. This means in concrete terms that with an assumed passenger boarding and deboarding time of one minute in the best case, the time for the same number of passengers in the worst case can be up to four minutes! It should be noted here that with some exceptions younger generation vehicles which are currently in operation tend to produce higher values.
The next figure presents the average the required boarding and deboarding time in different interior concepts (Tuna, 2008).

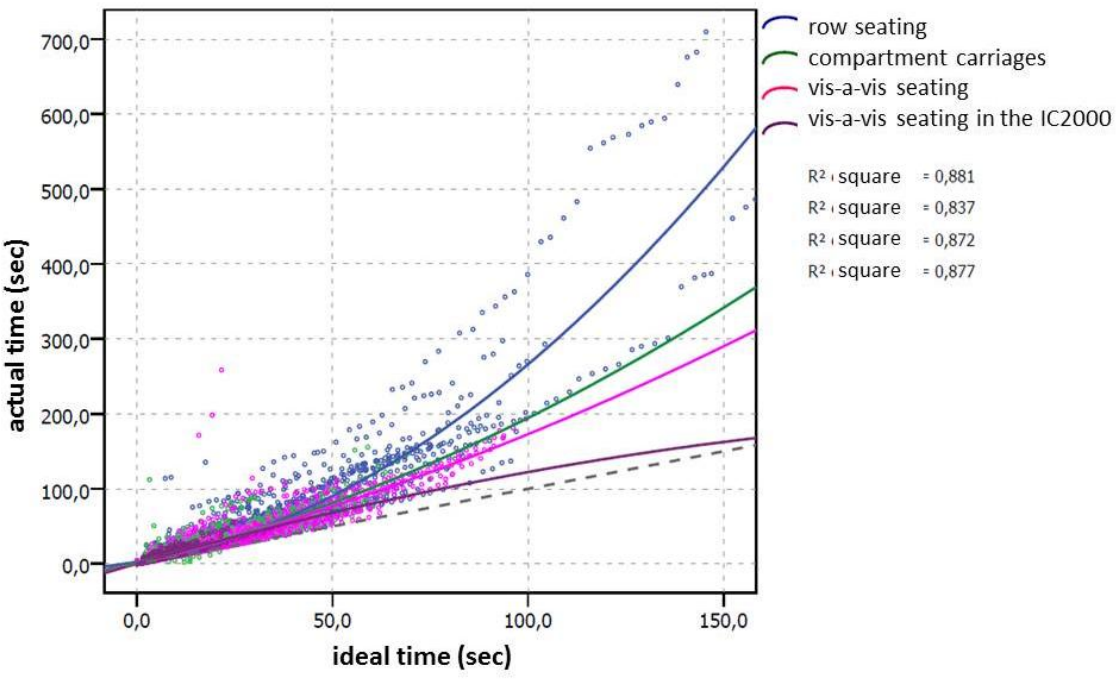

Fig. 4.
Time required for the boarding and deboarding process in different interior designs

The influence of interior design between the best and worst case already produces an affect with a ratio of 1:2 (see Figure 4). This means for example, in the best case at a high rate of passenger exchange in conventional vehicle constructions, a passenger boarding and deboarding time of two minutes can be achieved. Whereas, in the worst case it requires four minutes.
In Figure 4 fundamental concepts are presented; in such a way whereby in this example in row seating practically only overhead racks are available and in vis-a-vis seating luggage can be well stowed between the seat backrests. There is similar data from approximately ten basic vehicle interior categories. All findings show the clear correlation between

time demand and luggage storage. The more suitable the design of luggage storage areas, the less time is needed for boarding and deboarding.

5.2. Occupancy rate

From an operational point of view, the second relevant effect of well planned or vice versa insufficiently thought out luggage storage areas, is the actual occupancy rate.
In long-distance traffic the only significant occupancy rate is the seat occupancy rate. With unsuitable and insufficiently designed luggage storage possibilities, even this can decline noticeably. In conventional passenger carriages with a length over buffers of 26.4 meters, a maximum of 80 seats for standard days and 78 seats for travel days are provided (see Figure 5). This number is achieved if the remaining areas are used in suitable form for luggage storage. If this is the case, up to 100% of the seats can be occupied. If there are more seats over these limits, it is at the expense of customer-oriented luggage accommodation; and the actual number of available seats as well as the occupancy rate sink drastically. Previous studies by the Research Centre for Railway Engineering at the Technical University of Vienna show that the average achievable occupancy rate in comparable vehicles with 88 seats is only about 80%. This means that on average only 70 of the 88 installed seats can be used (see Figure 5)!
The reason for the sharp decline in occupancy is that there is not enough luggage accommodation capacity available and the existing areas are frequently unsuitably designed. This leads to the fact that part of the luggage is stored not only in the aisle but also on and in front of the seats.
The next figure presents the maximum possible number of available seats (Plank).

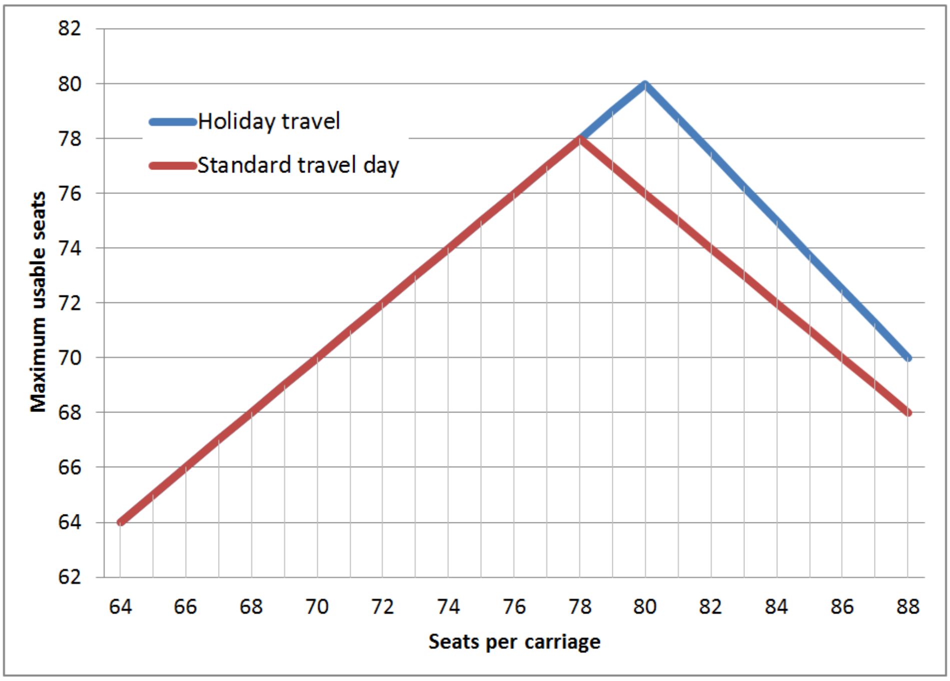

Fig. 5.
Maximum possible number of seats in passenger carriages with a length of 26.4 meters over buffers

5.3. Operating efficiency

The consequences of falsely planned luggage storage possibilities presented so far ultimately have significant operating efficiency impacts. The hope or goal to also be more efficient through a greater number of seats is transformed as a general rule into the opposite. Under the premise that the goal is to want to take advantage of the highest number of available seats, the following circumstances always prevail:

- **Delays:** Vehicle interiors following the idea of seat maximization inevitably lead to long station stop times. With a high passenger exchange, four to six minutes per station are the result. Whereas, ideally designed vehicles require only one to one and a half minutes. This fact in the case of a close sequence of stations leads to corresponding delays.
- **Declining operating quality:** When they cannot be made up for, the aforementioned delays lead to a decline in operating quality. This is especially important if delays are carried over to connecting or opposite trains, or if the results are missed connections.
- **Higher energy consumption:** If it is at all possible to make up for the delays, it is only possible by constant use of maximum line speed, which means a significant additional energy consumption especially at a high rate of speed.

- Lower occupancy rate: There are seats installed which in practice are not available. At the same time the achievable seat occupancy rate declines up to 20%!
- **Declining passenger satisfaction:** The declining seat occupancy rate causes a correspondingly high number of standing passengers, which accordingly reduces passenger satisfaction. Comfort is significantly reduced by the in part "chaotic" conditions in "overcrowded" vehicles. For nearly 18% of travellers high occupancy together with the already mentioned associated effects means a high stress factor!

5.4. Safety

The most important criterion which is often overlooked in insufficiently estimated operating efficiency considerations is safety. If in an emergency a train has to be evacuated, a large number of seats at a high occupancy rate in combination with the aforementioned effects presents a high safety risk. In air transportation a maximum evacuation time of 90 seconds must be proven before the certification of an aircraft.2 In railway transportation there are no such known provisions. However, it is understood that in most vehicles this time cannot be met. In a fully occupied carriage with 88 seats, the absolute exit time of all passengers under ideal conditions (no luggage during the exiting process, no backup because of crowding at the entrance door, only two steps) with the best carriage designs approx. 120 seconds is required and with the worst constructions, approx. 160 seconds.

In an incident, rising panic must be considered in which case an orderly exiting process cannot be expected. Above all, in this case improperly stowed luggage would lead to a corresponding safety risk! For this reason alone it must be ensured that for every installed seat there is also a suitable luggage storage space.

6. Fundamental planning errors

From past experience, both on the part of the purchaser as well as on the part of the manufacturer, fundamental errors which lead to the inefficient conditions described above can be identified in the planning and ordering process.

Error 1: Volume calculation: Every cuboid-like object has a volume and also three definite dimensions. As a rule In tender documents there is only information on the total volume required for luggage accommodation. For cuboids the volume is known as the product of width, length and height. This means that an often called for volume of approx. 0.125m³ per passenger can either correspond to the dimensions of a midsized trolley with dimensions of 50x70x35 cm, or at the same time, a trolley with dimensions of 1x4160x30 cm! Accordingly, it is also common practice to multiply every small cross-sectional area by the available depth and to sum the resulting volumes to a total volume! As a rule, in practice a maximum of 50% of the calculated volumes are available. It is therefore necessary to have precise knowledge of the statistical distribution, shape and dimensions of the luggage!

Error 2: Disregard of passenger behaviour: If the principles of "not lifting" and "visual contact" with regard to luggage storage construction are disregarded, the planned storage areas will be only in part accepted by the passengers. In practice this leads to the condition that up to 50% of all storage areas remain unused and yet a larger amount of luggage is stored disruptively.

Error 3: False awareness of luggage volume: The actual luggage volume has to be calculated for each route and expected passenger or travel purpose mix. Frequently blanket assumptions are made, or days are taken as a basis for calculation on which only a below average luggage volume can be expected.

Error 4: False dimensioning: Meanwhile, luggage accommodation is increasingly being taken into account in vehicles with regard to the installation of luggage racks and the space between the seat backrests. However, here it must be noted that the dimensions of luggage racks are often oriented to seat spacing resulting in very inefficient dimensions. The same can be observed in the spaces between the seat backrests. When dimensioning the respective storage areas it is advantageous to take into account the forms and dimensions of the luggage as well as the storage behaviour of passengers. Seat spacing and luggage racks are often dimensioned a few centimetres to small, which can lead to an actual storage loss of 50% or more.

Error 5: False evaluation criteria for orders: In vehicle orders it can often be observed that evaluation criteria are applied which are not logically understandable. A popular evaluation criterion in tenders is to define the minimum number of seats. Usually this involves specifications which can be classified as a psychological perception; and thus, they often jump to increments of 100. If for example in the tender as a fictitious number it is predetermined that a train must have 500 seats, then the hands of the manufacturer are already bound in the tender phase; and from the outset actually efficient solutions are not possible. These figures are usually based on a previously calculated maximum number per vehicle and thereby disregard reality. With the fictitious example mentioned it can be expected that a maximum number of 450 seats will actually be available in the train. Thus, it would be much more efficient to make no such requirement, but rather to allow the manufacturers to search for efficient overall solutions. With appropriate solutions it can be expected that vehicle design concepts can be found which in the example mentioned offer approx. 470 seats. Seats, which in the end can actually be used!

[2] http://de.wikipedia.org/wiki/Evakuierungssimulation

7. Conclusion

Fifteen years of research and development as well as participation in numerous vehicle plans make it clear that at all times with vehicle development and orders an overall optimum for vehicle interiors should be sought. Many negative examples make clear that the exclusive pursuit of a maximum number of seats can in practice lead to inefficient and dangerous situations. In particular, luggage storage possibilities must be precisely and thoughtfully planned in order to contribute to efficient overall systems. Experience further shows that it is very critical to lay aside blanket assumptions about design. Each vehicle must be assessed individually in terms of attainable overall efficiency which ultimately leads to an actual maximum seating occupancy.

Requirements for luggage storage must be thoughtfully formulated in the tender. Furthermore, in order achieve the greatest possible degree of efficiency, where and which luggage storage areas can be installed must be precisely considered in the beginning phase of vehicle planning. Later changes are usually achieved only with great difficulty or with little effect.

Fortunately, in recent times one can discern an awareness regarding these problems. Numerous recent projects confirm that both on the part of the operators as well as the manufacturers, interest in and willingness to develop efficient overall systems have emerged; and that some efficient overall solutions can be developed with negligible additional cost.

WHERE DO CYCLISTS RUN RED LIGHTS? AN INVESTIGATION INTO INFRASTRUCTURAL CIRCUMSTANCES

Tadej Brezina[1], Bernd Hildebrandt[2]
[1] *Vienna University of Technology, Institute of Transportation, Research Center of Transport Planning and Traffic Engineering, Vienna, Austria*
[2] *Austrian Transport Safety Board KfV, Department of Traffic Engineering, Vienna, Austria*

Abstract: Urban cyclists frequently run red traffic lights. This picture is commonly painted by media and public opinion. Our study aims at checking infrastructural influences on such alleged behaviour in order to brighten the view in this controversial public debate. We start by analysing accidents comprising cyclists running red lights. Based on Viennese intersections with an accumulation of red light infringements, the stop-willingness at red lights is studied in-situ. For traffic technological measurements, a total of 23 promising intersections is clustered by physical parameters in 5 settings. The parameters include classified cyclists counts, crossing length, number of crossed lanes, green and red time and compliance with the maximum waiting time according to the Austrian design guidelines. In addition test rides were carried out to estimate the proportion of waiting times to trip times and the traffic light density. The test rides revealed: average distance between traffic lights is 231 m and waiting time is about one quarter (25.9 %) of trip time. 19.2 % of 3,141 observed cyclists run the red light without stopping, while 11.5 % stopped before then running the red light. Therein the proportion of men was higher than with women (28.9 vs. 23.9 %). Cyclists disobeyed red lights about six times more often with demand button traffic lights than with regular traffic lights. As soon as only a single pedestrian crossing lay ahead, infringements happened 4.5 times more frequently than in other circumstances. In comparison to similar traffic volumes cyclists are awarded about 30 % less green time than motorized vehicles. Due to repeated de- and acceleration, the high traffic light density and proportion of waiting times have an obstructive impact on attractiveness for cyclists. Based on our findings we recommend measures to improve urban intersection design to facilitate ecologically attentive transport better.

Keywords: urban cycling, red traffic lights, cycling infrastructure, cycling safety, behaviour.

1. Introduction

A significant number of international studies are dealing with the subject of red light infringements which underlines its high relevance. The share of cyclists running red lights varies considerably. Ortlepp et al. (2008) as well as Johnson et al. (2011) both report that about 7 % of cyclists ran red lights. A range of 27.4 % in Netherlands to 30 % in the USA was reported by van der Meel (2013) and Monsere et al. (2012). The highest share is reported from China, up to 50 % (Wu, C., et al. 2012). Red light riding was found to be the second most frequent infringement among cyclists (Alrutz, D., et al. 2009). However, while 99.6 % of cyclists are aware of the correct behaviour at red lights, 45 % admitted to abide by these rules (Alrutz, D., et al. 2009). Van der Meel (2013) reports 27.4 % of cyclists infringing red lights – depending on location and layout. Alrutz et al. (2009), Johnson et al. (2011) and Van der Meel (2013) both find that males and young aged persons dominate in this behaviour over females and adults and senior citizens. All three studies also investigated infrastructural impacts on red light behaviour. The trends of their findings are summarized in Table 1.

Table 1
Infrastructural parameters' impact on red light riding behaviour from existing literature

Infrastructure parameter	Impact on red light riding
Traffic volume	Lower red light cycling share for higher traffic volumes
Duration of green phase	Lower red light cycling share for longer green phase
Duration of red phase	Higher red light cycling share for longer red phase
Crossing distance	Lower red light cycling share for longer crossing distance
Riding direction	Higher red light cycling share for right turns than for straight ahead rides
Sighting distance	Lower red light cycling share for limited sighting distances
Centre island	Higher red light cycling share when centre island is present
Velocity of lateral traffic	Lower red light cycling share for higher velocity of lateral traffic
Composition of lateral traffic	Lower red light cycling share for higher share of trucks and busses

Between 2000 and 2003 about 18 % of lethally crashed cyclists were involved in red light infringement crash (Lutschounig, S. and Robatsch, K. 2005). Based on Vienna's total traffic accident database, Fig. 1 and Fig. 2 show distributions of red light infringement casualties of cyclists related to day time, week and month. Along with the general timeline of cycling volume, a definite peak can be found between 3 and 6 pm, while night hours result in very little crashes. During the week, most incidents take place from Monday to Thursday. During the course of the year, the months from May to August show the highest numbers and incidents in fall are more frequent than in spring.

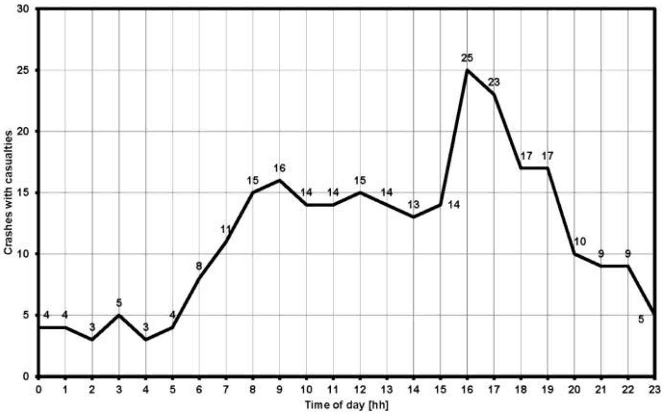

Fig. 1.
Timeline of cyclists' red light infringement crashes with casualties in Vienna from 2004 to 2013 (n=272)

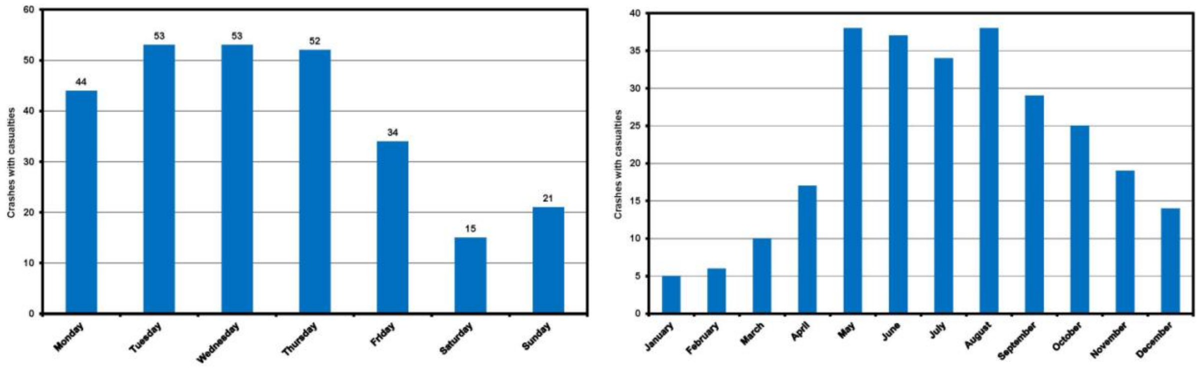

Fig. 2.
Cyclists' crashes with casualties in Vienna from 2004 to 2013 by days of week (left) and by month (right) (n=272)

In principle drivers for red light infringement can be grouped in personal, non-influenceable critera and influenceable traffic engineering criteria. Our task of research was to focus on the latter and find the impact of transport infrastructure design features on the frequency of cyclists infringing red lights. The second section delimits the materials and methods that are used in field study and analysis. Section three shows the results of analysis and the final section provides conclusions from the survey to be used for the improvement of intersection design.

2. Materials and Methods

Two survey methods are used:

- Seven test rides on a bicycle. These rides criss-crossed densely built-up central Vienna were 3.06 to 6.58 km long and took between 14 and 30 minutes to ride while traversing 14 to 32 traffic lights,
- In-situ, stationary measurements of cyclists' behaviour at 18 pre-selected traffic lights clustered in 5 settings in Vienna. The sites are located in densely built-up central Vienna within or closely outside of the second ring road (Table 1).

The choice of intersections for the in-situ measurements is based on intersection typology and layout and on the analysis of disaggregated Viennese crash data (see Table 2). After a brief pre-survey, three sites per setting were chosen to be studied in depth.

Table 2
Clustering of 23 survey sites

Setting	Number of pre-selected sites	Number of surveyed sites	Number of observations	Sites located in Vienna's districts
1 – Cycling path crosses one car lane	5	3	668	1, 4, 15
2 – Cycling path crosses more than one car lane	5	3	943	1, 4
3 – Push-button traffic light for cyclists	5	3	337	1, 4, 20
4 – Cycling path crosses pedestrian path	5	3	609	2, 7
5 – Cumulation point of cycling crashes after red light violation	3	3	584	8, 9, 16

The in-situ measurements took place for 2 hours per site during weekdays and included the behaviour of 3,141 cyclist in total, mostly males in the age class of 25 to 65 years (Fig. 3. left). In comparison to Vienna's total distribution (Fig. 3. right), male riders aged 25-65 are over-represented in our sample. Jellinek et al. (2013) reported an age distribution among cyclists as follows: 5 % children younger than 14 years, 13 % of youngsters between 15 and 24 years, 68 % of adults between 25 and 65 and finally 14 % of senior citizens beyond the age of 68.

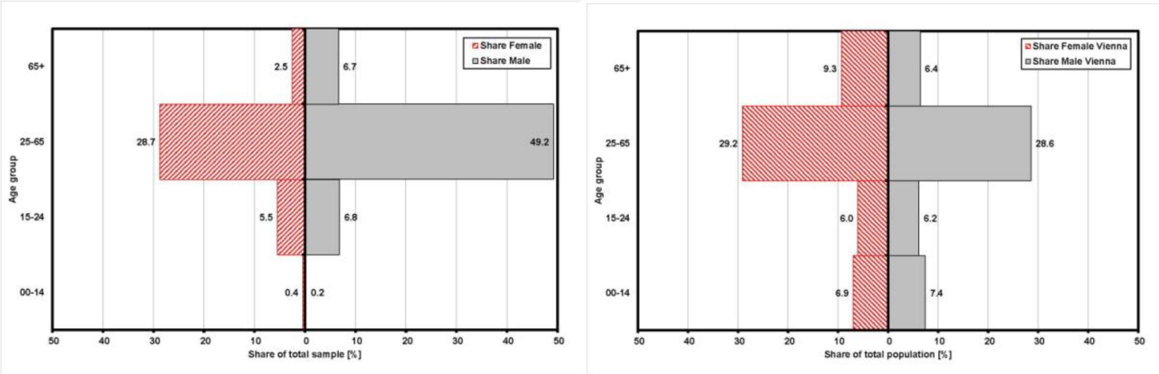

Fig. 3.
Age distribution by sex of observed cyclists (n=3,141) (left) and of Vienna's total population (n=1,840.226) at January 1st 2016 (right)

3. Results

The seven test trips resulted on average in:

- 4.3 traffic lights per trip km.
- 16 seconds waiting time per intersection.
- 71 seconds waiting time per trip km.
- 25.9 % as ratio of waiting time to total trip time.
- 231 m average distance between traffic lights.

Six types of cyclists where distinguished by studying red light behaviour:

- Red riders in middle red-phase who do not wait before riding, i.e. crossing without hesitation
- Red riders in middle red-phase who wait before riding, i.e. crossing after a full stop
- Late riders in early red-phase, crossing shortly after the end of the green phase
- Early riders in late red-phase, crossing shortly before the beginning of the green phase
- Green riders who wait at red and wait for green before riding.
- Green riders who arrive at green and do not wait before riding.

For all survey sites the types of observed behaviour is shown in Fig. 4. 1,124 of 3,141 cyclists (35.8 %) ride when their light is still showing red. This red-riding rate varies strongly by location from around 11 % up to 80 %. Compared to the international numbers given in the introduction, Vienna is among the leading group. However, this value is not representative for all of Vienna's intersections as it was the task to find and survey some of the most problematic sites. More than half of red riders passed without stopping. 35.2 % of riders waited in front of the red light to turn green before continuing to ride. More than half of the red riders crossed without stopping.

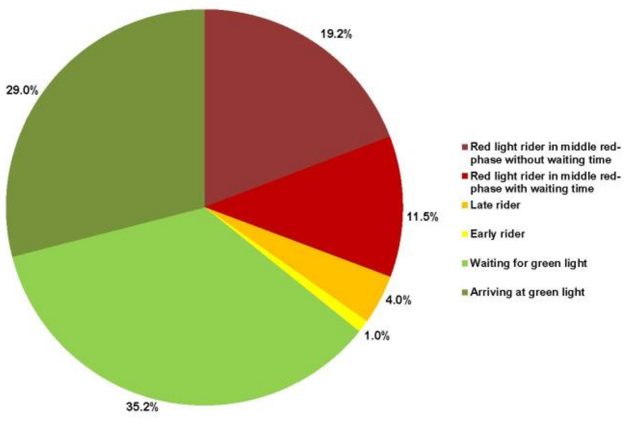

Fig. 4.
Red and green light riders for all survey sites by type of behaviour (n=3,141)

19.2 % of 3.141 ran red lights without stopping, while 11.5 % stopped briefly before running the red light. Therein the proportion of men was higher than with women (28.9 vs. 23.9 %). Cyclists disobeyed red lights about six times more often with demand button traffic lights than with regular traffic lights. If only a pedestrian crossing lay ahead, infringements happened 4.5 times more frequently than in other circumstances. The distinction by sex shows a male prevalence by a factor of 1.2 over female riders. Youngsters ran the red light 1.6 times more frequently than adults.
Distinguishing rider types by surveyed settings reveals a more diverse picture (Fig. 5). While all other settings show a disobedience rate of about 30 %, setting three "Push-button traffic light for cyclists" reveals about 70 % of riders running red lights. On the other hand sites from setting five, the culmination points of bicycle crashes, showed the least infringement rates (18.5 %). The share of green riders strongly depends on duration of green and red phases and the coordination of the traffic light with its adjacent traffic lights. At 4 out of 15 surveyed locations, disobedience rates reached more than 50 %.

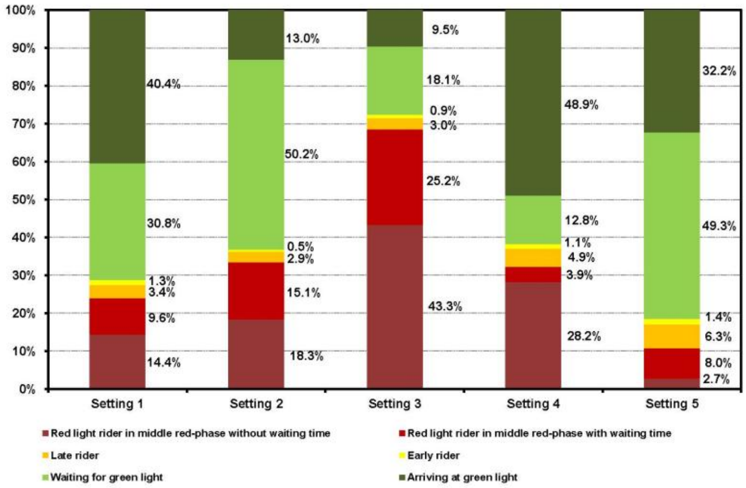

Fig. 5.
Red and green light rider behaviour by setting (n=3,141)

By excluding riders that arrive at green from the total sample, the willingness to stop can be derived. In this case, settings three and four show the lowest willingness to stop: 20.0 and 25.1 %. The three remaining settings feature willingness shares bigger than 50 %: from 51.8 to 72.7 %. Settings three and four are sites with Push-button traffic lights for cyclists and intersections where cycling paths cross only pedestrian paths.
Where the red phase lasted 60 seconds or longer, cyclists run the red light 2.7 times more often than in sites with shorter periods. At push-button traffic lights (setting 3) the disobedience rate was 6 times higher and at intersections with only a pedestrian walkway it was 4.5 times higher than in the remaining settings.
Finally we analysed the sites' impact on relation between share of cyclists arriving at green and the ratio of green to red phase time (Fig. 6). In addition we plotted the relation of average waiting time to green time coefficient over the share of red riders (Fig. 7). These diagrams show:

- That cyclists tend to arrive at green lights more frequently when the green time's share increases,
- That cyclists tend to infringe red lights more often when average waiting time increases over green-time.

Average waiting time is better suited for explanatory means than red phase duration as it implies the coordination with preceding traffic lights.

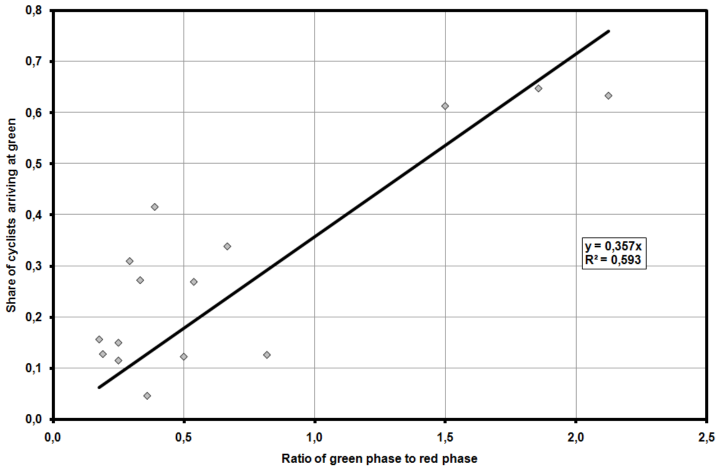

Fig. 6.
Green to red time ratio over green riders without waiting time (n=15)

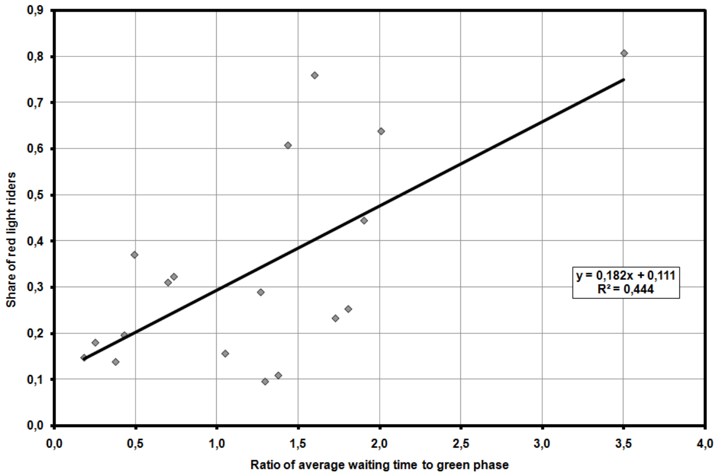

Fig. 7.
Average waiting time to red time ratio over red riders (n=18)

4. Discussion and Conclusion

The high density of traffic lights and the long waiting times considerably reduce the potential for cycling in Vienna. Under the premise of travel time stability, waiting times in extent of 25 % of total trip time reduce possible trip lengths by about one quarter. In addition, recurring bicycle de- and acceleration due to the high traffic light density of 4.3 traffic lights per km increases rider energy expenditure.
Applied to car traffic only, ease of traffic flow is considered the highest priority. For the same amount of vehicle throughput, this reduces green time for cyclists by 70 %. The crucial advantage of higher throughput of cyclists per unit of width is thus forfeited. As 14 out of 23 traffic lights showed red phases longer than 40 seconds, a large portion of studied traffic lights can be considered as cyclist-unfriendly. A low acceptance (inverse figure of disobedience) asks to be interpreted as indicator of low bicycle friendliness. Settings three and four with their significantly high disobedience rates teach us that such designs shall be avoided.
Only 1 out of 1,124 observed red cyclists had a conflict situation with a car driver. Red cyclists cautiously observed crossing traffic regarding approaching vehicles and their time gaps before infringing the red light.
The limitations of the study at hand suggest in-depth work to implement improvements and perform the following measurements:

- Time gaps between crossing vehicles,
- Velocities of crossing vehicles,
- Sizes of arriving cyclist groups,
- Distinction between cyclists riding straight on and those turning right into the crossing traffic.

Based on our findings we suggest measures to improve urban intersections insofar that infrastructure design supports ecologically attentive transport. Our recommendations are:

- Reduce density of traffic lights in general,
- Reduce average waiting times to below 40 seconds,
- Avoid waiting times of 60 seconds or longer,
- Give cyclists traffic lights of their own instead of combining the with a pedestrian lights,
- Avoid push-button traffic lights,
- Introduce coordinated traffic lights for cyclists – “green wave”,
- Study and then introduce right turn on red for cyclists, as it is already common in many other countries (Netherlands, France, Belgium or Switzerland).

RULE BENDING IN THE ROAD BASED COMMERCIAL GOODS TRANSPORT SECTOR - A SYSTEMS THEORY APPROACH

Christian Henrik Alexander Kuran[1], Ove Njå[2]
[1,2] University of Stavanger, Norway

Abstract: Intentional bending of safety related rules by actors in the road based commercial goods transport sector is a significant but understudied phenomenon. The sector in question is characterized by its complexity, the large number of actors involved, and by being hard to regulate. Cross border- and multimodal transport activities is a central contributor to the sectors complexity. The difficulty of introducing and enforcing workable international safety regulations and standards on international business is apparent; when we consider that individual actors working in different phases of the transport chain are often bending rules. We approach rule bending using systems engineering analyses of safety. The paper presents findings form the initial part of an ongoing double layer-category focus group design. Grey areas of rule bending in the transport chain was discussed in three focus groups consisting of transport workers, terminal workers and transport managers. The preliminary findings show that both self-reported and observed bending of rules is common in the phases of the transport chain explored in the study. Commonplace rule bending may lead to a breakdown in the feedback loop necessary to maintain safety as an emergent aspect of the transport system.

Keywords: rule bending, road based transport, safety engineering, focus groups.

1. Introduction

In this paper, we present the initial findings from three focus group interviews, and outline the potential for systems theory as a theoretical framework for analysis of rule bending in the road based commercial goods transport sector. (Leveson 2011) It is common knowledge that safety related rules are bent and even broken in many different sectors of society. Rasmussen and Svedung state that in the case of complex sociotechnical systems that indeed: "Rules and laws are never followed to the letter practically speaking". (Rasmussen & Svedung 2000:13) Rule bending is an understudied phenomenon in the road based commercial goods transport sector, and the regulatory bodies have a tendency to suppose that rule and regulations are usually followed. (Njå, Braut et al. 2012) The interviews discussed are the first three in an ongoing PhD-project, which also includes literature reviews, ethnographic fieldwork and survey methods. The project uses a joint framework of systems theory of complex sociotechnical systems, and ethnographic methodology. (Gobo 2008, Leveson 2011)
Rule bending as an academic term is commonly used in sociology of law (Canales 2011), and may be defined according to Sereka and Solin as following: "Rule bending involves a decision to go around the formally stated obligations by not fully following a rule, requirement, procedure or certification in totality" (2007). There are two problems with this definition. First, that it presupposes both the rule benders knowledge of, and intent to go around a rule or stated obligation in order for his actions to qualify as rule bending. Thus, the definition both excludes intentional and non-intentional lack of knowledge of said rule or obligation. During controls and audits in the road based commercial goods transport sector, ignorance of safety related rules and regulations does not excuse either rule bending or rule breaking. Second, the definition does not problematize that the bending of rules has a highly subjective component, as illustrated in figure 1. The same action described as rule bending by a transport company could be considered rule breaking by a government controller. The project of which this paper is a small component, aims to describe the grey areas of rule bending by charting variance in the performance, justification and rationalization of rule bending behavior in the transport sector.

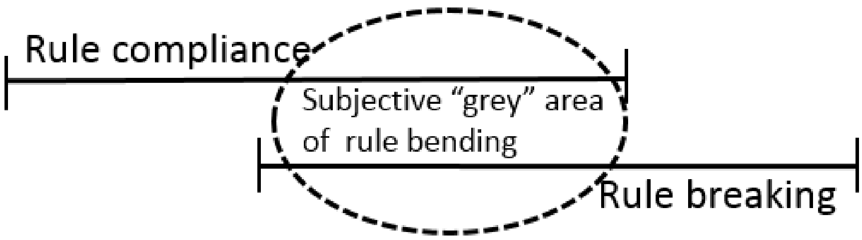

Fig. 1.
Subjective area of rule bending

2. Theory

The need for a systems theory perspective to be utilized in the analysis of safety and accidents in the road traffic sector is being voiced by several transport researchers. (Salmon, Read et al. 2012, Scott-Parker, Goode et al. 2015, Young and Salmon 2015) In systems theory sociotechnical systems are analyzed by analytically reducing the systems to a

[1] Corresponding author: christian.h.kuran@uis.no

hierarchical model, describing control through constraints, such as regulation and policy from one level of the hierarchy to the levels beneath it. (Salmon and Lenne:2015) In systems theory safety is described as an *emergent* property of the system. The reference channel and measuring channel is utilized in such a way as to allow a feedback loop from operational experience to be reflected in the goals, policies of the higher levels in the system and allowing for the control commands to be utilized properly. The reference and measuring channels are illustrated in figure 2.

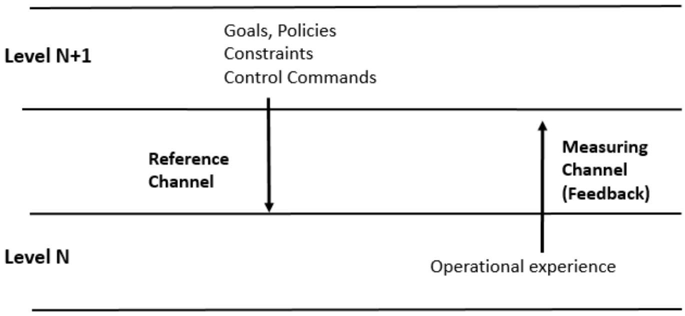

Fig. 2.
Hierarchic control structure in systems theory
Source: (Leveson 2011:83)

A hierarchical model of sociotechnical control in the road based transport sector is described in figure 3. The sampling of informants in the focus group study has been made in order to cover the company, operations and operating process levels in the model.

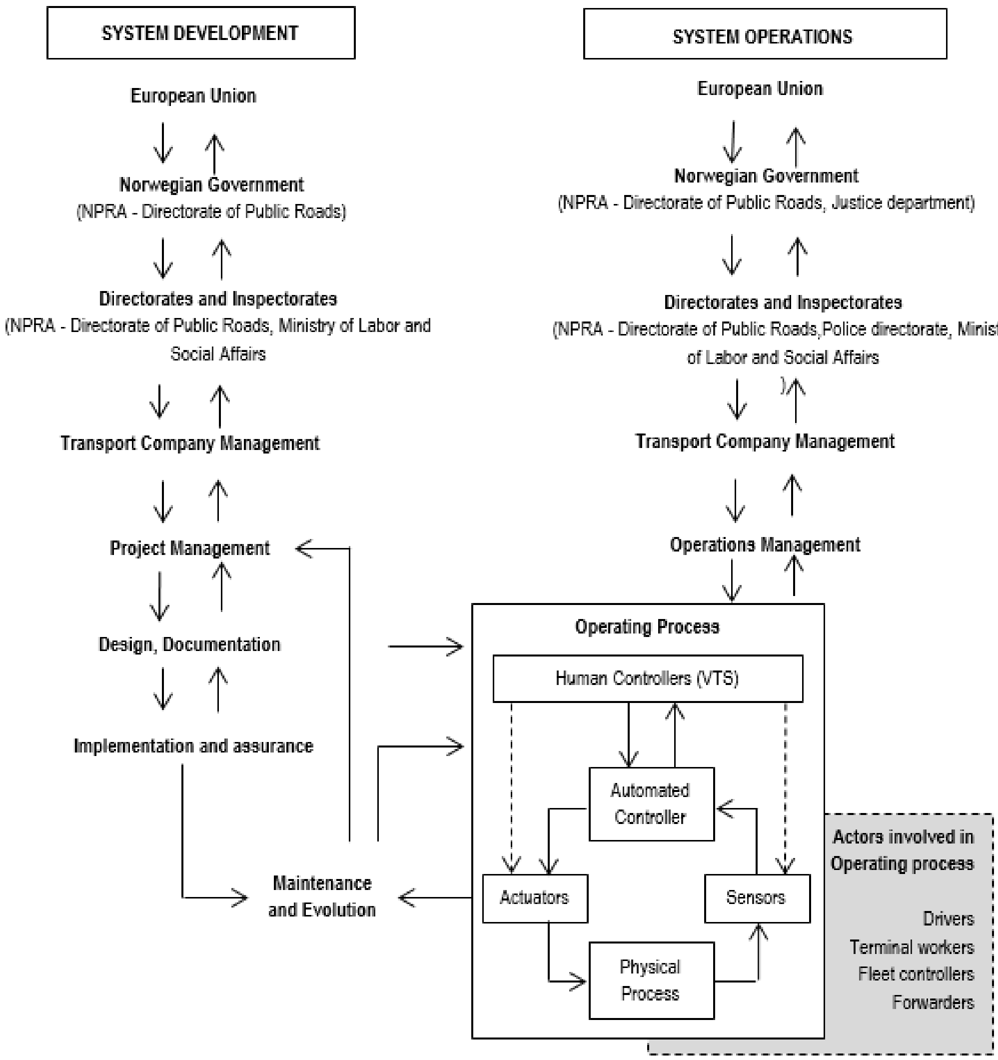

Fig. 3.
Model of sociotechnical control in the road based transport sector
Source: (Leveson 2011:82)

3. Method

In the sampling of informants for the three focus group interviews we made use of a “purposeful sampling strategy’(Creswell 2012), in which we reflected on whom to recruit. Our purpose of using focus groups in this study is to recruit a group of people each with a certain set of experiences and knowledge, to discuss rule bending. (Bernard 2006:323) We established a formal setting where all the informants where aware of the goal of the study, and where the moderator started each group by introducing the theme of the study. The moderator further guided the conversation with open-ended questions and ensured that all of the members contributed. The interviews where audio recorded, and the audio was transcribed shortly after the interviews in order ease the transcription process.
We recognized two major challenges during the data collection. First, that some participants dominated the conversation and compromised the available speaking time of other participants. Second, that some participants may for differing reasons have felt the need to censure their opinions or omit experiences. The reasons for non-compliance may stem from the fact that rule bending can be considered a sensitive topic. Our recognition of these two challenges guided out data collection. In the three focus group interviews, we attempted to dismantle hierarchy by reminding the participants that they have similar background, field of interest and social characteristic. (Krueger and Casey 2015) The moderator also fostered a certain methodological naiveté during interviews, allowing the participants to explain certain concepts or procedures in detail.
Our categorization and recruitment of informants for the interviews was guided by the categorization implicit in the hierarchical structure of systems theory. (Leveson 2011) All informants have so far been recruited from local companies and from local branches of national transport companies in Stavanger, in Western Norway and Fredrikstad, in eastern Norway. In the project, our planned data collection so far consists of 12 focus group interviews, four categories of participants in what is called a double layer focus group design. (Krueger and Casey 2015) An overview of the groups is shown in in table 1.

Table 1
Double layer category focus group design

Category	Vest Norway	East Norway
Transport workers	00	00
Terminal workers	00	0
Fleet controllers	0	0
Transport managers	0	0
Mixed group	0	

The inclusion of a mixed focus group may be considered a small methodological experiment within the bounds of the study. Since heterogeneous groups are discouraged by the methodological literature, due to self censure, we have included one such group to see if self-censure will occur. The informant’s respective reactions and discussions about rule bending in their line of work will in turn increase our understanding of the behavior and rationality of actors in the sector. Findings in the study might also be applicable for the analysis of rule bending in other modes of transport. Each focus group concluded after an hour and a half of discussion, and followed the same thematic conversational guide as outlined in table 2.

Table 2
Conversational guide

	Moderator Task or Question
1.	The moderator presents the theme of rule bending in the commercial goods transport sector.
1.	The moderator ensure that all group participants in turn present themselves, and their work tasks.
2.	The moderator ensure that all group participants in turn are invited by the moderator to say a few thoughts on the topic by answering the following question: - What kind of experiences do you have with safety related rules being stretched or bent in your place of work?
3.	The moderator opens free discussion of the topic
4.	The moderator guides the conversation back to the topic if the informants trail of for long.
5.	The moderator ensure that the discussion does not de-rail using one or several of the questions below. The same question may put more than one time to different participants. 1. What does a standard work process start? 2. Where in the transport chain is your work process? 3. Can you describe a task? 4. Who do you communicate with during the performance of a task? 5. What experiences have you with that rules are stretched in the business? 6. Can you / you give an example of a way to bend the rules? 7. I have focus group participants in other interviews who have other responsibilities and

	tasks such as dispatchers, drivers, terminal workers or fleet managers, do you have experience with that they are pushing rules? 8. How do they do it? 9. Does it affect you? 10. Why do you think safety related rules are bent during the transport chain? 11. How are experiencing control from the authorities? 12. Can you give an example of a control? 13. Concluding and summarizing question: Is it realistic to expect that some of your tasks always adhere strictly to the rules?

The subject of this paper, three groups, have so far been moderated:

3.1. Group 1

Group 1 was a homogenous group comprised of four terminal workers in a small company in West Norway. Each of the workers had several years of experience in the transport sector, and as terminal workers in the current and other companies. There was little or no self-censure and several examples of self-reported and observed rule bending was described by the participants.

3.2. Group 2

Group 2 was a homogenous group comprised of three transport workers with several years of experience as truck drivers in both local distribution and transnational transport. All where currently active in the transport sector and based in eastern Norway. There was no self-censure and several examples of self-reported and observed rule bending was described by the participants.

3.3. Group 3

Group 3 was a heterogeneous group comprised of a transport manager, a fleet manager and transport worker, and a terminal manager. The mixed group was characterized by some self-censure. Still many examples of self-reported rule bending was described by the participants.

4. Findings

In the course of the focus group interviews 22 concrete examples of rule bending behavior was self-reported or described by the informants. An overview of the behavior is shown in tables 3, 4 and 5, along with the Norwegian or EU law, regulation or directive it is associated with and divided by category.

Table 3
Rule bending actions self-reported or observed among transport workers described by informants in the focus group interviews

Rule Bending Task	EU/Norwegian Rule, Regulation Bent or Broken
Trucks loaded with inappropriate cargo, or inappropriate combination of cargo	FOR-2009-04-01-38 (Directive on professional transport), LOV-1974-12-20-68 (law on transport agreements)
Not loading or emptying own vehicle	LOV-1965-06-18-4 (law on road traffic)
Violating hours of service or rest hours regulation	FOR-2012-06-28-794 (AETR agreement)
Alerting other drivers about road side controls	FOR-2009-05-13-590 (Directive on road side controls)
Use of illegal or falsified documents	FOR-2009-04-01-384, LOV-1965-06-18-4 (Law on road traffic) FOR-2008-04-16-362 (directive on
Failure to have the proper documentation for cargo	FOR-2003-03-26-40 (Directive on commercial transport) , FOR-2009-04-01-384
Arbitrary truck maintenance	FOR-1994-10-04-918 (directive on vehicles)
Not securing container legs	LOV-2005-06-17-62 (law on working environment)
Not aiding in the unloading or loading of cargo	LOV-1965-06-18-4 (Law on road traffic)
Bypassing equipment used measure service and rest hours	FOR-2012-06-28-794 (AETR agreement),
Use of intoxicants such as alcohol	LOV-1965-06-18-4 (Law on road traffic)

Table 4
Rule bending actions self-reported or observed among terminal workers described by informants in the focus group interviews

Rule bending task	Rule, Regulation or Norm in Breach
Loading and fastening not appropriate for cargo or vehicle	FOR-2003-03-26-401 (directive on commercial transport along roads)
Loading and fastening of cargo not done by part responsible for cargo	FOR-2003-03-26-401 (directive on commercial transport along roads)
Handling loading, unloading of heavy equipment without the proper safety documentation	LOV-2005-06-17-62 (law on working environment)
Not documenting near-accidents	Directive (EU) 2015/413 – sharing information on road traffic offences

Table 5
Rule bending actions self-reported or observed among terminal workers described by informants in the focus group interviews

Rule bending task	Rule, Regulation or Norm in Breach
Drivers pressured by management to break speed limits or rest.	FOR-2005-06-10-543 (Directive on working hours for drivers and others in the road transport sector)
Collective freights badly managed	LOV-1974-12-20-68 (law on transport agreements)
Planning unrealistic or illegal routes	FOR-2005-06-10-543 (Directive on working hours for drivers and others in the road transport sector) FOR-2007-07-02-877(Directive on drive and rest – hours within the EES)
Not documenting near-accidents	Directive (EU) 2015/413 – sharing information on road traffic offences
Obscuring conditions at own workplace during control or audit	LOV-2005-06-17-62 (law on working environment) FOR-1996-12-06-1127 (directive on internal control)
Falsification of documents	FOR-2003-03-26-401 (directive on commercial transport along roads) FOR-2009-04-01-38 (Directive on professional transport)

All participants admitted that they “could get better at following rules”, but at the same time “that rules and regulations was often considered a hindrance for the flow of day to day business and problem solving”. An overview of which phase in the transport chain the described rule bending behavior was self-reported or observed is shown in figure 4.

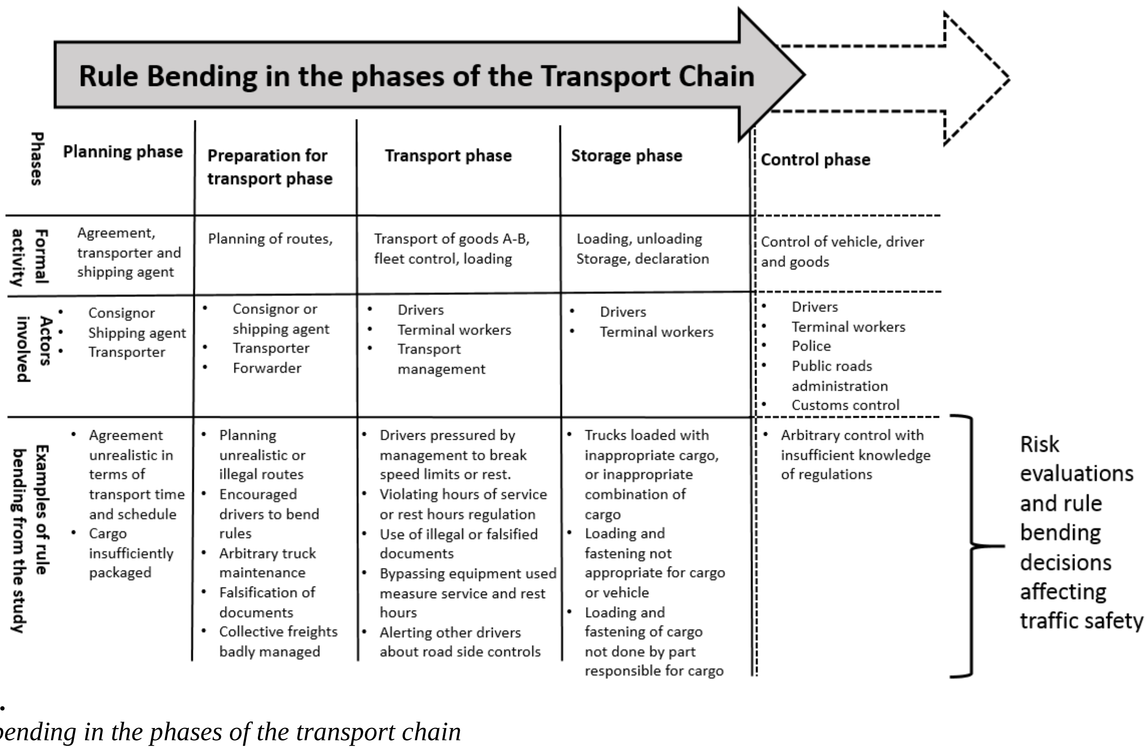

Fig. 4.
Rule bending in the phases of the transport chain

5. Discussion

In the focus group interviews several subjects where discussed in addition to the descriptions of different kinds of rule bending behavior. Examples include:

1. Does the lack of knowledge about safety procedures excuse rule-bending behavior?
2. When does the responsibility for the safety of a process enter or leave the individuals realm of responsibility?
3. Is it rule-bending behavior not to report or sanction observed rule bending behavior?
4. Can some rule bending behavior have possible positive effects?

While the informants recognized that rule bending behavior in several phases of the transport chain might in turn lead to unsafe condition and accidents, they urged that rule bending is an unavoidable necessity in their line of work, or “simply how business is done”. In discussing this further, the informants reported of perceived grey areas of responsibility between the necessity for rule compliance in order to preserve safety on one side, and on the other side the necessity to “cut corners” and “bend rules” in order keep their respective companies responsibilities to their customers, and continue to make a profit. Transport and terminal leaders communicate these twin factors of safety and profit in both subtle and not so subtle ways throughout the workday.

It is reasonable to consider that the grey areas rule bending might endemic in the commercial goods transport sector, in all phases of the transport chain. Grey areas where known to all informants in the study and highly prone to subjective interpretation by the individual. To maintain the flow of a work process and “live up to the expectations” of the companies customers, a transport manager will leave it to a transport worker to maneuver within a grey area where rules are bent and corners cut. The manager expects the worker to maintain the work process within reasonable bounds of safety but it is also known on both levels of the hierarchy that safety is the suffering part in the safety/profit dichotomy. The communication between the levels in the hierarchy about these grey areas is an informal one. This informal channel is shown in figure 5. as included in the systems theory model by the authors.

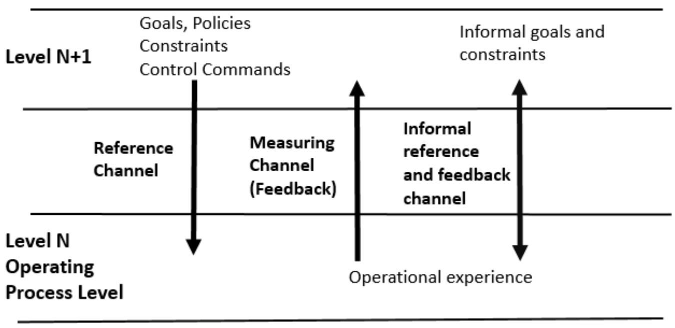

Fig. 5.
Hierarchic control structure with informal goals and channels
Source: (Leveson 2011)

It is possible to imagine grey areas of rule bending as an emergent property of the sociotechnical system. The consideration of alternative emergent properties in the road traffic system has also been the focus of research by Young and Salmon in their study on distracted driving as an emergent property of the road system. (Young and Salmon 2015) The maintenance of safety as an emergent quality of the transport system hinges on the continuous feedback loop of reference and measuring. As long as control and feedback is consciously utilized, the safety of the system will increase correspondingly. This perspective does not include that informal communication create grey areas of rule bending as continuous parts of the same system. Informal communication exists parallel to the feedback loop and may take precedence. This can lead to a breakdown of the measure and reference feedback loop, in turn reducing safety as an emergent property of the system.

6. Conclusion

The overall project will continue to observe and describe the creation and maintenance of grey areas of rule bending through informal communication, and their associated concrete methods of rule bending in the transport sector. More qualitative research is necessary in order to explore the informal practices, and the safety related consequences of rule bending. A focus group study is comprised of three or four group interviews in each category of participant, after which the researcher determines if saturation is achieved. (Krueger and Casey 2015:23) The term saturation describes a point in the research where the researcher does not attain any new information. This study has not reached yet reached that point, but we hope the overall project will.

Acknowledgements

The study is dependent on the continuous aid of both companies and individuals in the transport sector. For this, we are most grateful.

STUDY ON BEHAVIORAL ANALYSIS OF DRIVERS: A SURVEY WITH QUESTIONNAIRES

Francesco Saverio Capaldo[1], Francesco Abbondati[2], Mario De Luca[3]
[1,2,3] Department of Civil, Architectural and Environmental Engineering (DICEA), University of Naples Federico II, Italy

Abstract: The road transport system is based on driving characteristics: a large amount of accidents is related to more or less serious violations of rules of the Highway Code. It is obvious that different drivers have different behaviors in the same situations, less obvious is to know what percentage of a given population has some similar behaviors (e. g. due to factors such as driving experience, age and/or sex) and how this knowledge can help in the road studies. To learn the driver's behavior, it can be useful to measure road speed (V_{85} or operating speed) in some default road situations (geometrical or environmental). Often the recorded data, when numerically significant, tend to a normal distribution. In some cases it is possible to define different data distributions where to was appreciated the contribution of two very different driver's behaviors. In order to better characterize the different driver's behavior a survey with questionnaires is started. The survey modules are composed with multiple sections. The starting section containing personal data is investigated with Dula Dangerous Driving Index (DDDI), Driver Behaviour Questionnaire (DBQ), Traffic Locus of Control Questionnaire (T-LOC), Marlowe Crowne Social Desirability Scale (MCSD), Car Selection (CS), Car Characteristics Selection (CCS). The questionnaire is filled by 300 persons, and the answers are checked and analyzed. For example with the DDDI, different driving styles are identified, with the DBQ some types of recurring errors. At the end it is possible to analyze the responses also in terms of age and sex and these have highlighted attitudes such as the driving anger, the risk perception, the potentially risky behavior, the anxiety, the perception of control, the respect for the rules. The results obtained indicate that the survey must be continued to improve the driver’s characterization.

Keywords: behavioral survey, driver’s behavior, behavioral questionnaires, driver’s characterization.

1. Introduction

Road transport is still dangerous: in Europe every year more than 1.2 million road accidents are recorded in which about 50,000 people die and 2 million are injured. Road accidents in Italy are the leading cause of death for people between 15 and 24 years. There are many causes of accidents due to factors related to vehicle, to safety devices, to road or to environment; often a combination of these variables is present, but the human factor still remains responsible for more than 80/90% of accidents. Many accidents are due to violations of road safety rules. The most typical violations are excessive speed, dangerous overtakings, unwary crossing, non-respect of safety distance, driving vehicles under bad mechanical conditions that are a threat to safety.

The driver is the best safety road device: this statement is true only if the driver is disciplined and well-informed on the road and flow conditions. Young people is a category of vulnerable drivers, because of their short time of driving experience. Young people is less skilled to estimate and perceive risks and often they challenge their own limits, overvaluing their own capabilities. The road accident is a probabilistic event where the lower attention of the driver increases the chances of putting in danger their safety and that of other persons.

The knowledge of the behavioral characteristics of drivers is very important in order to study road safety. Structural approaches to prevent road accidents (improving quality of roads and their design, introduction of active and passive safety systems in the construction of motor vehicles and other technologies) are beginning to produce positive results, but the unpredictable and wrong driver behavior still remains a strong obstacle to road safety.

The behavioral study can be led through different methodologies: road measures of the velocity vector (intensity, direction and variation) or its statistical determinations (operating speed, V_{85} etc) through different detection systems (Dell'Acqua and Russo, 2010 ; Dell'Acqua, 2011b; Discetti et al., 2011; Dell'Acqua et al., 2013c; Dell'Acqua, 2015; Capaldo, 2004b) or in different geometric conditions of road (Capaldo, 2012b; Capaldo and Biggiero, 2014).

A different approach uses answers directly from drivers on behavior and attitudes in certain situations and tries to correlate the given answers to some factors that can be measured in a different way. In this work the driver behavior is investigated with interviews of 300 persons with a set of different questionnaires, preceded by some personal information: Dula Dangerous Driving Index (DDDI), Driver Behaviour Questionnaire (DBQ), Traffic Locus of Control Questionnaire (T-LOC), Marlowe Crowne Social Desirability Scale (MCSDS), Car Selection (CS), Car Characteristics Selection (CCS).

The analyzed answers clarify certain behavioral aspects of the test subjects and also some correlations between the behavioral characteristics of some classes of age and the choice of the car and its main features.

2. Methodology and the different questionnaires

The work, shown here in a significant but not in a definitive step, starts from an initial data collection, limited to main behavioral questionnaires available in the literature. From personal data, regarding age, driving experience, suffered/caused accidents, the questionnaires collect information with: DDDI, DBQ, T-LOC, MCSDS (see Table 1). After analyzing the answers of 150 participants, two new sections are added to questionnaires: Car Selection (CS) regarding questions on choosing the car based on the price and Car Characteristics Selection (CCS) regarding questions

[1] Corresponding author: fcapaldo@unina.it

on the desirable characteristics of the chosen vehicle. For each participant were collected personal data as well as more than 100 responses for the different sections of questionnaires. Summary characteristics of each of the tests are shown in Table 1.

Table 1
Different questionnaires, autors and references, items for questionnaire, results and acronyms

Questionnaire	Autor/Ref.	Items	Results
Dula Dangerous Driving Index (DDDI)	Willemsen, J., Dula, C. S., Declercq, F., Verhaeghe, P. (2008)	27 items	Risky Driving Subscale (RDS) Aggressive Driving Subscale (ADS) Neg. Cognitive/Emotional Subscale (NC/ES) DDDI Dangerous Driving Total Score
Driver Behaviour Questionnaire (DBQ,)	Lajunen, T., Parker, D., Summala, H. (2004)	34 items (adapted)	Aggressive Violations Subscale (AVS) Ordinary Violations Subscale (OVS) Errors Subscale (ES) Lapses Subscale (LS) DBQ Total
Traffic locus of Control Questionnaire (T- LOC)	Ozkan, T., Lajunen, T. (2005)	18 items	Others Internal Vehicle/Environment Fate T-LOC Total
Marlowe Crowne Social Desirability Scale (MCSDS)	Crowne, D. P., Marlowe. D. (1960)	9 items (reduced)	Percentage of max value (9)
Car Selection (CS)	Capaldo, F. S.	9 items	Far desired passenger car
Car Characteristics Selection (CCS)	Capaldo, F. S.	7 items	Far desired car features

2.1. Dula Dangerous Driving Index

The wrong driving behavior is the result of emotional factors. For a long time scientific literature did not have a definition of the aggressive driving that could allow researchers to work on a common basis. To fill this gap, Dula and Geller (2003) propose an aggressive driving model based on three different attitudes while driving: ability to accept risk, intentional acts of aggression towards others, negative perceptions/emotions.
These factors are measured with the DDDI (Dula, Ballard, 2003), which shows adequate psychometric properties. Different test studies found that risky driving shows strong correlations with the number of received violations and the number of road accidents. In most cases, men report higher scores of aggression than women.
The questionnaire consists of 27 statements that express a positive or negative attitude to a specific object. The sum of these judgments tends to outline the driver attitude. For each statement, respondents are asked to indicate the level of agreement or disagreement in a defined scale, specifically a 5 step scale in this work.

2.2. Driver Behavior Questionnaire

Even in Italy, as mentioned before, at least 80/90% of accidents is due to inappropriate driver behavior, therefore it is legitimate to say that most of accidents are due to incorrect driving rather than technical reasons. To analyze driver behavior deeper it is necessary to evaluate his reactions in different circumstances.
Reason (1991) defines an error in all the cases where a planned sequence of physical or mental activities fails its purpose and when this failure cannot be attributed to the intervention of some random agent. More in detail a driver's risk behavior may be due to errors or violations. Unlike errors, violations are defined intentional, although both can be potentially cause accidents.
In later studies Lawton (1997) extends the scale of the violations to incorporate new elements. Factorial analysis shows that violations can be divided into two types, depending on the reason why drivers violate: aggressive violations, in which there is a violent interpersonal component, and regular violations, deliberate but in which there is not necessarily an aggressive purpose.
Another factor that distinguishes the driver's behavior is not intentional actions, but lapses, which is related to inattention or memory gaps that may occur while driving.
DBQ is used to evaluate these elements and it is used in studies conducted in the UK and in other international contexts. Data are collected from: Australia (Blockey and Hartley, 1995), China (Xie et al., 2003), Greece (Kontogiannis et al., 2002), Finland and the Netherlands (Lajunen et al., 1999; Mesken et al., 2002), New Zealand (Sullman et al., 2000), Sweden (Åberg and Rimmö, 1998), and Turkey (Sümer et al., 2002).
The original structure of the questionnaire (Reason, 1990; Reason et al., 1990) is based on four factors: aggressive violations, ordinary violations, errors and lapses. This work investigates 34 situations with 6 evaluation steps.

2.3. Traffic Locus of Control Questionnaire

The T-LOC can be defined as the degree to which the person generally perceives external events and classifies them within their ability to control, within the control of other subjects, to external factors (e. g. due to environment) or to fate.

The concept of locus of the internal / external control is endorsed for the first time in 1954 by Julian Rotter (Rotter, 1954) and there are two kinds. *Inside* is the kind owned by drivers who believe in their ability to control events. These subjects attribute their successes or failures to factors directly related to the use of their skills, willingness and ability. *Outside* is the kind held by those who believe that the incidents are not the direct result of personal capacity, but of unforeseeable factor such as other subjects, external factors or the case, fate. This work investigates 18 situations with 5 steps.

2.4. Marlowe Crowne Social Desirable Scale

Some participants, compiling questionnaires that assess their personality, temperament or behavior, tend to emphasize their best points and often deny or minimize their deficiencies and failures, trying to show that they are close to rules and standards of the civil society. Crowne and Marlowe (1960) develop a scale to identify the degree to which persons have this propensity. The original formulation include 33 items. In this survey the statements are reduced to 9 with binary response (true or false): this number is considered more than enough to provide a general indication on the behavior of the interviewed.

2.5. Choice of the ideal cars and their most desired features

In the survey, a list of cars, currently in production, divided by categories (City car, Small, Compact, Medium, Superior, Sport, SUV, Mini Van, Multi-space) is submitted to participants asking them to choose a model regarding the price or maintenance cost (CS, cfr. Table 1 for acronyms). A further section (CCS) showing the characteristics of the cars such as the power type (Petrol, Diesel, LPG/Methane, Hybrid, Electric) and other features (Reliability, Comfort, Consumption , Entertainment, Aesthetics, Manageability, Performance, Safety, Technology), asks if those features are essential or unnecessary for their ideal car. These last two sections try to investigate possible correlations between behavioral characteristics of participants and choice of car.

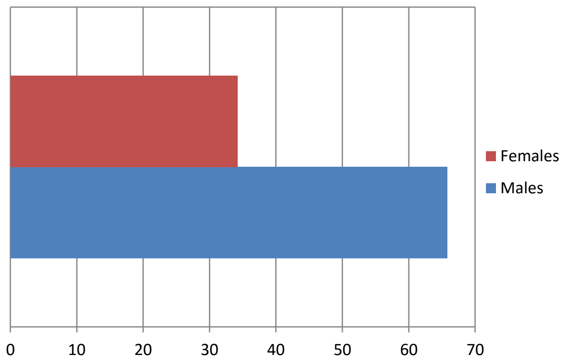

Fig. 1.
Survey data: Percentage of male and female subjects)

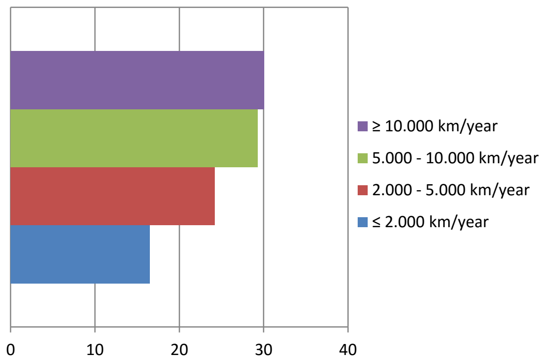

Fig. 2.
Survey data: Percentage of km/year of driving

3. Participants

The questionnaires are submitted to the students of the course of Construction Road, Railways and Airports of the University of Naples Federico II. So the sample is unbalanced because it is formed by young drivers with little experience. To balance the sample a set of questionnaires was dispensed to subjects with a different age.

A total of 300 drivers participated to the present study. The age range is between 19 and 74 years, with a mean age of 36 years and a prevalence of age between 19 and 35 years. 67% of drivers are men and 34% women. On average, the drivers have their license since 16 years and have driven approximately 10.000 km in the previous year (Table 2 and Fig. 2).

Fig. 3 shows the age distributions of the interviewed subjects compared with the adult Italian population and Fig. 4 the distributions of three different age classes adopted as regards to Italian population in 2015.

4. Data analysis and results

The DDDI, like the other indicators, is analyzed by sex and by age class of participants. The maximum values for each section are: 55 RDS (cfr. Table 1 for acronyms), 45 for NC/ES and 35 for ADS with a total value of 135 on 27 items. The graphs of Fig. 5 and 6 show the percentage difference of average values of the distributions for each section with respect to the central value of interval (e. g. 27.5 for the RDS).

Table 2
Survey data: some statistical parameters of participants (Age, Years of driving license, Km/year, Total accidents number)

Stat. Par.	Age	Lic. Years	Km/year	Tot. Accident N.
Min. Value	19,00	1,00	-	0,00
Max. Value	74,00	65,00	-	11,00
Average	33,86	15,95	10.476	0,82
Std. Dev.	14,23	13,22	6.812	1,32
85° perc.	54,00	34,20	-	2,00

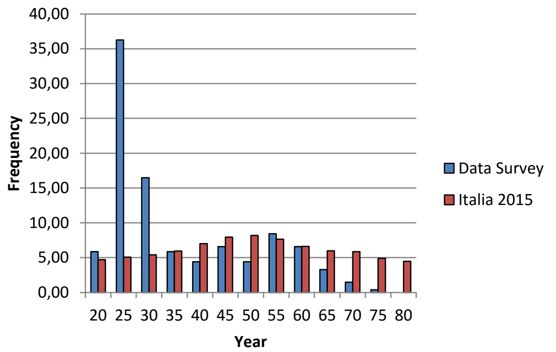

Fig. 3.
Difference between survey distribution classes and that of the Italian population by 2015

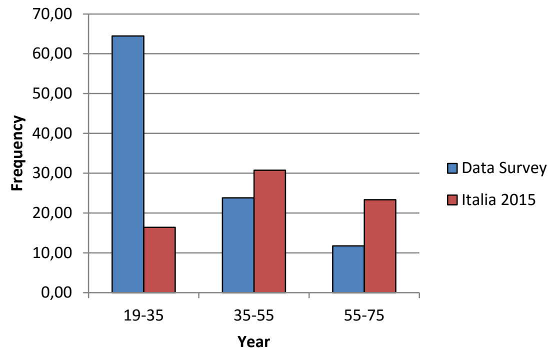

Fig. 4.
Difference between three distribution classes used with that of the same classes of the Italian population by 2015

Fig. 5 shows the experimental values as percentage differences relative to the central value of the interval of values for each subsection. The sample analyzed by gender indicates a total DDDI of about 8%, with women who have a greater difference than men (-10.1 and -7.3). The single factors analyzed show a trend similar for RDS and ADS and obviously opposite for NC/ES. The analysis by age group (see. Fig. 6) indicates that mainly participants over 55 (-15.0) contribute to the value obtained by DDDI, followed by those of other two classes (-13.4 and -5.3). Similar developments have RDS and ADS. For NC/ES those over 55 continue to maintain a basically positive attitude (-4.9) as well as to a lesser extent the 36-35 year class drivers (-1.0).

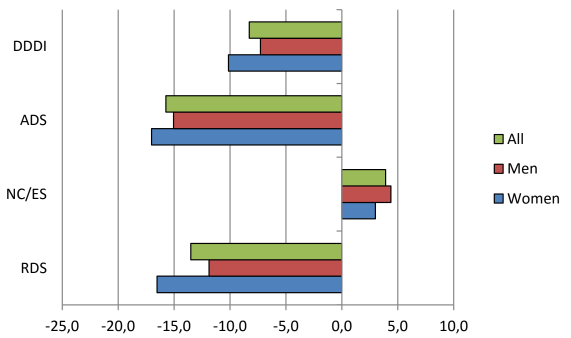

Fig. 5.
DDDI and subsection by participant sex

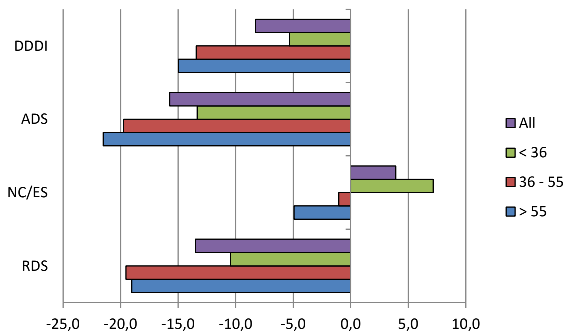

Fig. 6.
DDDI and subsection by participant age class

At end it can be said that almost all the participants have described themselves as very careful drivers. Male drivers are lesser cautious than females and younger drivers clearly lesser prudent than those over 55.
For the DBQ the same analysis and result presentation are done. Fig. 7 shows the values by gender and Fig. 8 by age group. The sample by gender shows, in Fig. 7, a total DBQ around -15.9%, with women who have a higher difference than men (-16.9 and -15.3). The single factors show a similar trend for Agg. Viol. (-15.8 and -15.6). Women are

significantly more correct than men for Ord. Viol. (-16.6 and -9.9) and tend to commit lesser errors (-22.2 and -21.3). However, they have declared themselves more vulnerable to lapses (-13.2 and -18.2). The analysis by age group (see. Fig. 8) shows that the best behavior (declared) is over 55 (-22.2) followed by the other two classes (-19.6 and -13.5). A similar trend is seen for all subsections of test.

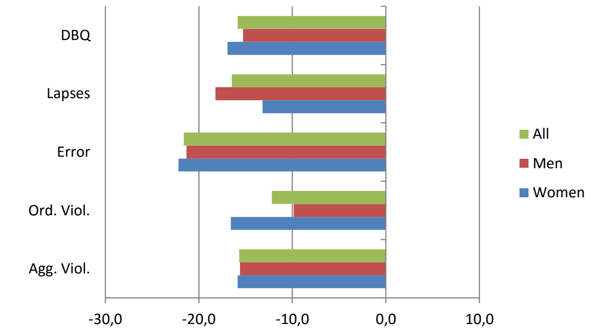

Fig. 7.
DBQ and subsection by participant sex

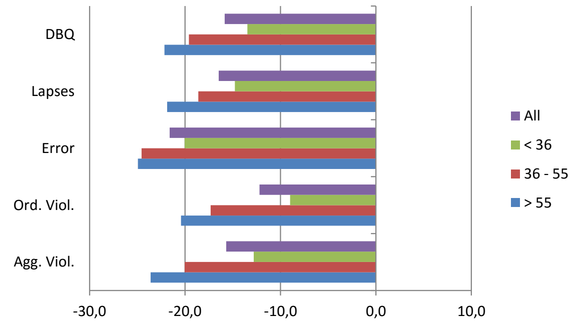

Fig. 8.
DBQ and subsection by participant age class

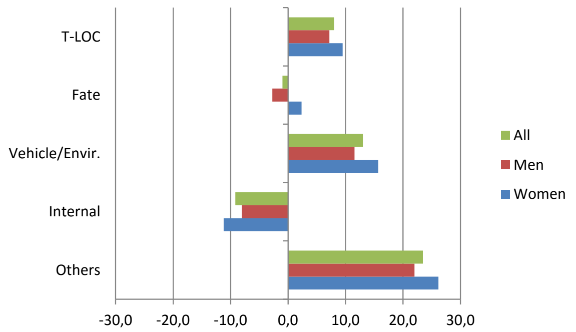

Fig. 9.
T-LOC and subsection by participant sex

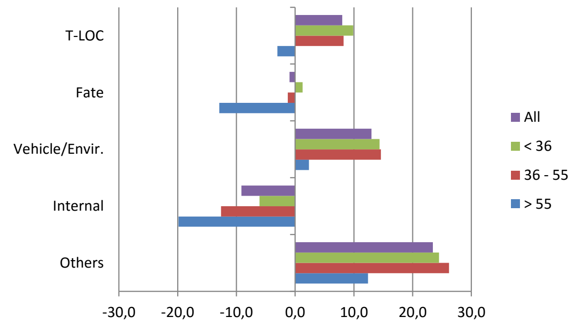

Fig. 10.
T-LOC and subsection by participant age class

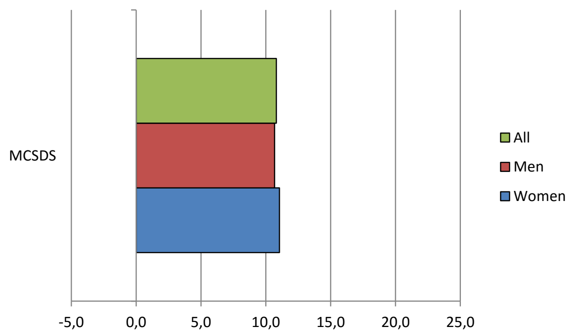

Fig. 11.
MCSDS and subsection by participant sex

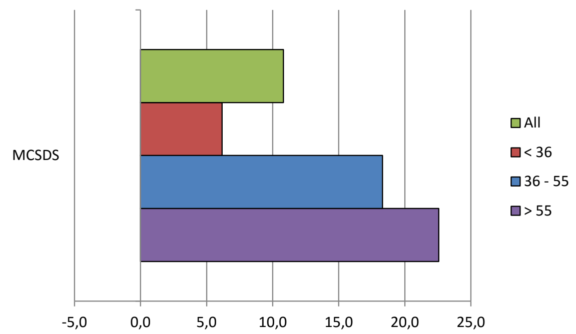

Fig. 12.
MCSDS and subsection by participant age class

Participants have declared a good driving behavior. Even in this case, the females seem better than the males, and younger drivers seem to have a worst behavior than those over 55.
The T-LOC (Fig. 9 and Fig. 10) closes the series of self-assessment questionnaires for drivers: it investigates what factors seem responsible for accidents not directly under their control (Others, Vehicle/Environment, Fate) and which under the driver's control (Internal). The factors independent from the driver's control are predominant. The gender analysis shows that women absolve themselves, imputing the possibility of an accident to factors out of their control. Men describe themselves slightly better and it seems that they do not believe in Fate in the case of accidents.
Considering the age groups, even drivers over 55 seem to be more inclined to admit their responsibility in a road accident, and they definitely exclude the possibility of an intervention of Fate.
At the end, drivers tend to blame all the possible faults of road incident to everyone except themselves. They believe that they might be involved in an accident for events that are not under their direct control and they are very sure of their driving skills.
But how much participants in their answers were sincere? It can make a judgment? Based on observations made by

other authors (Wahlberg et al., 2010; Lajunen and Summala, 2003; Fischer, 1993), the behavioral survey is completed with a smaller version of MCSDS. The results are shown in the graphs of Fig. 11 and Fig. 12.
It seems obvious that all the persons interviewed try to appear better and behaviors are quite similar when analyzed by gender. It has to be underlined that the difference from a neutral behavior (0% difference) is only about 10%. Younger persons seem more sincere than those of over 55 (Fig. 12). Overall, the result seems more than acceptable.
Table 3 shows the best correlation between the personal data of all respondents and total values of the questionnaires. The kilometers traveled / year and the number of accidents (fortunately very few for each subject; there is only one case with a total of 11 of which 8 under its own responsibility!) have a very little influence. Contrarily the results of the questionnaires appear very influenced by the subject age, by the years of the license acquisition and by the ratio between this information and age.

Table 3
Survey data: correlations between some parameters and result values of questionnaires

	Age	Lic. Years	Lic. Years/Age	DDDI	DBQ	T-LOC
Age	1					
Lic. Years	0,959314	1				
Lic. Years/Age	0,876014	0,951299	1			
DDDI	-0,412652	-0,404724	-0,39613	1		
DBQ	-0,444285	-0,427717	-0,41371	0,727783	1	
T-LOC	-0,286068	-0,284269	-0,24146	0,305104	0,289261	1
MCSDS	0,304299	0,273681	0,22802	-0,332601	-0,369179	-0,09551

A list of cars grouped into different categories (City car, Small, Compact, Medium, Superior, Sport, SUV, Mini Van, Multi space) is submitted to 120 persons interviewed. They have to choose only one according to their own preferences without considering the cost. After they have to identify which characteristics influence the choice of the car: Power / Fuel, Reliability, Consumption, Performance, Safety, Versatility / Adaptability, Aesthetics. The answers are limited to only three characteristics. For each category (CS) and each feature (CCS) a score is given according to the road safety. Fig. 13 and Fig. 14 show the percentages of the choices made by the participants for CS and CSS.

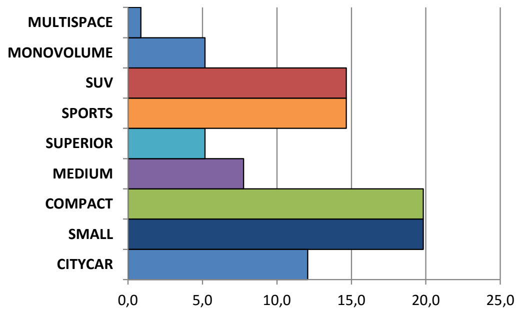

Fig. 13.
CS (Car Selection) percentage

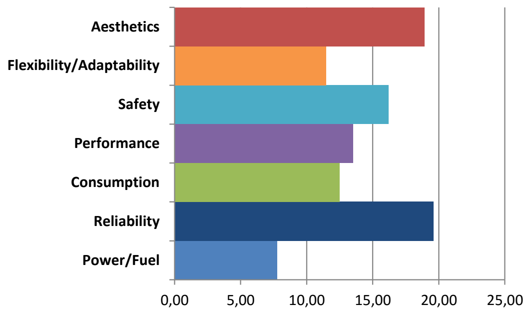

Fig. 14.
CCS (Car Characteristics Selection) percentage

Table 4
Survey data: correlations between ratio Years of driving license/Age, CS, CCS, CST and DDDI

	Lic. Years/Age	CS	CCS	CST	DDDI
Lic. Years/Age	1				
CS	-0,22639	1			
CCS	-0,27983	0,426969	1		
CST	-0,30378	0,746412	0,920469	1	
DDDI	-0,43782	0,394630	0,313871	0,401545	1

Table 4 indicates that the best correlation is between the sum of the scores assigned to CS and CCS (CST) and the DDDI index. Other correlations with different indices and the characteristics of the cars have given worst results.
Fig. 15 and 16 show DDDI as a function of CST. Fig. 15 shows the Total DDDI and Fig. 16 the DDDI referring only to male subjects. Both figures show that a correlation exists between the choice of the car, its characteristics, and the greater or lesser aggressive behavior of drivers. This relationship requires further investigations. This part of analysis concerns only 120 interviews compared with nearly the whole 300. The link between the choice of the characteristics of

the car and score obtained with DDDI is stronger for males than females. The analysis of age groups (<35, 36-55,> 55) shows that only for those over 55 the correlation between DDDI and CST has acceptable values although low. The other two classes have lower values of the slope of fit line.

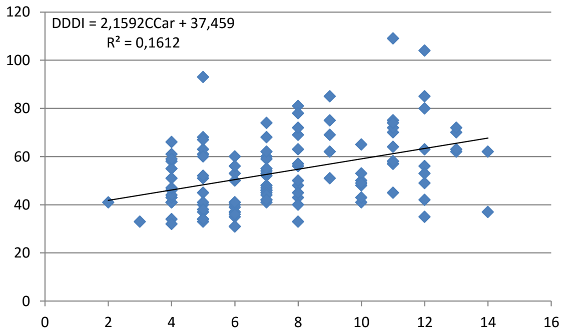

Fig. 15.
DDDI Total versus CST

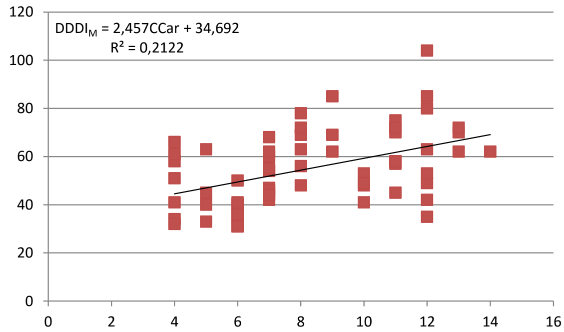

Fig. 16.
DDDI for men versus CST

5. Limitations

The surveyed sample has a prevalence of young peoples and this will be corrected with subsequent interviews. Even the statistical analysis is limited to a few essential indicators. At the end of this work it is not possible to include other 150 questionnaires already filled.
The study is limited by the perceived biases associated with self-report methodology, and in particular the potential for obtaining socially desirable responses (Wåhlberg et al., 2010). Importantly though, Lajunen and Summala (2003) directly examine DBQ responses and find that the influence of social desirability on responses is not substantial and is lesser when completed in privacy. Participants in the current study complete the questionnaires in their own time and the confidentiality of their responses is assured. Therefore, the impact of social desirability on responses is minimal: the reduced MCSDS value is about 10% (value determined as the percentage difference between the average experimental MCSDS and its central value of definition interval).

6. Conclusions

The goal of this work is to investigate through known questionnaires on driving attitudes a large, representative sample of Italian drivers. During the data collection it was thought that might somehow try to correlate attitudinal results of drivers to external elements such as the car models or something on the car characteristics or his choice.
The survey (now and even if with some limitations) collects a large number of information on drivers for different age groups, involves 300 subjects who provided, through the answers, at least 45.000 elementary information that is still under partial processing.
Data are collected through known questionnaires (DDDI, DBQ etc) and a control of the reliability of the answers is provided (MCSDS). This work tries to correlate some of the DDDI results with information supplied by interviewees that concerned the choice of the car. Preliminary results show a clear correlation between aggressive drivers and high-powered cars and/or sport cars.
In transportation simulations field conditions, road geometry and driver behavior in traffic flows must be replicated and driving behavior is one of the crucial points in modeling traffic flows as highway traffic or road maneuvers.
An increase of the survey data and the use of different statistical analysis on large amounts of information (e. g. covariance analysis, factorial analysis, data mining etc) will lead to more reliable results and will enable to recognize prevailing attitudes of drivers by recording the car models in traffic flows.

Acknowledgements

Special thanks to all those who contribute to this work and the patience they have by compiling long form; among them the students of the courses of Construction Road, Railways and Airports at University of Naples Federico II, their parents and all the others involved.

PEDESTRIAN LEVEL OF SERVICE ANALYSIS AND EFFECT OF ARCHITECTURE

Ilker Erkan[1]
[1] *Süleyman Demirel University Faculty of Architecture, Isparta, Turkey*

Abstract: This paper presents a literature review of pedestrian level of service (PedLOS) evaluation at various facilities such as sidewalks, intersections and crosswalk locations, and highlights the need for further Pedestrian LOS studies at crosswalks, under mixed traffic conditions, from the perspective of Turkey. The crosswalk is one of the most complex locations for pedestrians, bicycles, involving interaction with vehicular flow in different locations such as signalized or un-signalized crosswalks. The Complete Architectural Design Strategies (CADS) to be adopted for evaluation of a pedestrian facility changes with facility type. The Complete Architectural Design Strategies at crosswalks depends on numerous factors, including pedestrian safety, delay, available vehicular gaps and pedestrian as well as pedestrian behavior and vehicular driver behavior. In this case, it can be seen reflection of architecture. However, only limited studies have been carried on PedLOS using these factors. In this paper, the available literature is discussed, and the greater importance of sidewalks pedestrian level of service.

Keywords: pedestrian level of service, architectural utility, pedestrian dynamics, level of service, complete architectural design strategies.

1. Introduction and Literature Review

Assessment methods and level of service (LOS) standards vary according to the type of user (pedestrians, bicyclists, transit users, and vehicular drivers). In developing countries like Turkey, transport policies including roadway design and management, and investment programs, tend to favor of motorized traffic over non-motorized modes such as pedestrians and bicycles. Little attention has been given to reducing risk in non-motorized modes of transport. There is a need to provide mobility and ease of access for non-motorized modes, in order to help develop a sustainable transportation system. The design of such diverse user facilities is a complex task for Turkey's transportation engineers and designers. The Transportation Research Board (TRB, 2011) has defined the following definition for level of service:

- LOS A represents free flow,
- LOS B is in the range of stable flow, but the presence of other users in the traffic stream begins to be noticeable,
- LOS C is in the range of stable flow, but marks the beginning of the range of flow in which the operation of individual users becomes significantly affected by interactions with others in the traffic stream,
- LOS D represents high-density, but stable, flow and speed and freedom to maneuver are severely restricted, and the driver or pedestrian experiences a generally poor level of comfort and convenience,
- LOS E represents operating conditions at or near the capacity level and all speeds are reduced to a low, but relatively uniform value,
- LOS F is used to define forced or breakdown flow so this condition exists wherever the amount of traffic approaching a point exceeds the amount which can traverse it and queues begin to form, operations within the queue are characterized by stopping and starting".

In the case of transportation facilities, successive versions of the Highway Capacity Manual (HCM) have introduced new factors such as freedom to maneuver, traffic interruptions, comfort, and convenience (HCM, 2010).
Compared with motorized traffic, little attention has been paid to non-motorized road users such as pedestrians and bicycles under mixed traffic conditions. Rapid population growth and urbanization have produced a steep increase in the use of motor vehicles. The number of registered vehicles in Turkey increased from 10.236.357 in 2004 to 17.939.447 in 2013, an increase of 75.3% (TUIK, 2014). As the population continues to increase, transport behavior (pedestrian behavior and the number of vehicles) on the road are very important measures of life quality and mobility. Pedestrian walkways are used by a variety of users, including pedestrians with disabilities and wheelchair users. The design and evaluation of walkway facilities is therefore much more complex than roadway design (Landis et al., 2001).
On the other hand pedestrian level of service is first criteria that think about starting to design. Erkan et al. (2016) conducted an LOS study of the movement and circulation of elderly people in airports, and suggested that the mobility of elderly people is a key factor in Pedestrian level of service (PedLOS).
The first Pedestrian LOS study (Fruin, 1971) was based on capacity and pedestrian volume in sidewalk facilities. It calculated the CADS from pedestrian flow rates, pedestrian speed, and area modules (the inverse of pedestrian density). Several subsequent LOS studies have applied these measurable parameters to different walkway facilities (Polus et al. 1983, Tanaboriboon & Guyano, 1989). Researchers have identified problems with the freedom to choose pedestrian speeds at sidewalks, and have explored new factors like travel time and its relationship to density, defined as a queuing relationship (Rahman et al., 2013). Other studies have extended the pedestrian equivalent factor under heterogeneous traffic conditions to the evaluation of pedestrian facilities (Galiza & Ferreira, 2013).

[1] Corresponding author: ilkererkan@sdu.edu.tr

Pedestrian flow characteristics have also been used to evaluate facility of architectural design (like sidewalks, streets, urban furniture etc.), using parameters such as pedestrian speed, flow rate, and density as CADSs. Studies have been conducted at a range of at different locations, including central business district areas (Al- Masaeid et al. 1993) and passenger terminal locations (Yang, 2010). A range of linear models have been applied (Virkler & Elayadath, 1994) at different facilities (Lam & Cheung, 2000). Research has been conducted in mixed traffic conditions (Laxman et al. 2010), and using simulation based approaches (Teknomo, 2006). All these studies used quantitative approaches, and neglected qualitative factors such as comfort, safety, and street attractiveness.

2. Material and Method

We placed to Bluetooth device in the street that detecting pedestrian on the sidewalks. We count to pedestrians with these devices with Bluetooth sensors (Figure 1).

Fig. 1.
Bluetooth device that placed on the street

As methods to extract the count and flows of pedestrians from Bluetooth detection logs, while considering the data management scheme on a mobile ad hoc network (Nishide & Takada, 2012) in case study area (Figure 2) in Turkey.

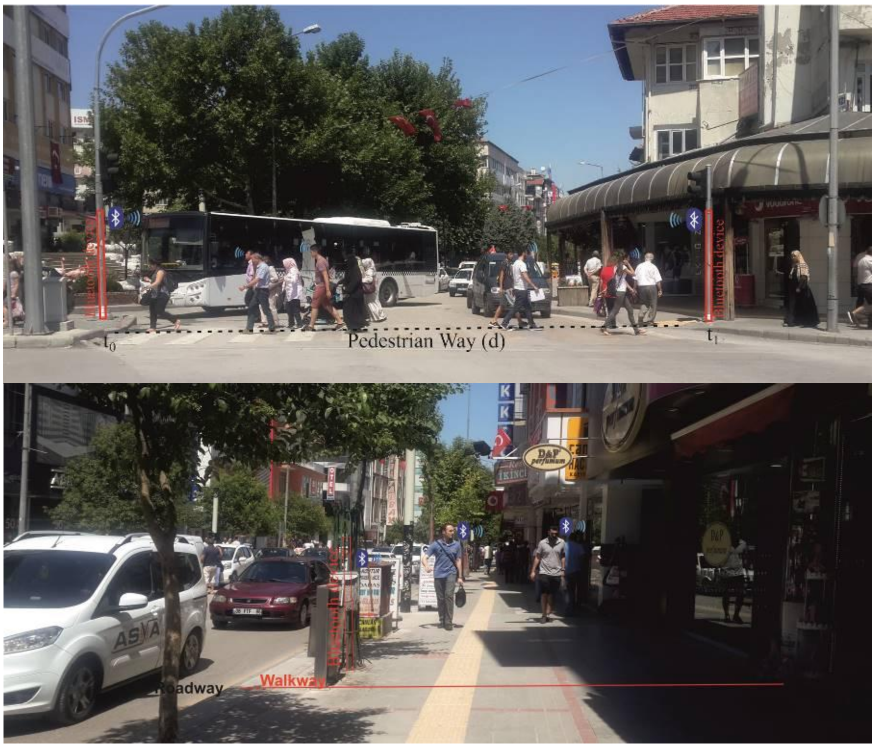

Fig. 2.
Case study area

All the observations were made by 1812 people. Results from such a small sample size cannot be generalized for large population. The aesthetic quality of the walking environment has a considerable influence on one's perception of safety and/or comfort but in our study participants were encouraged to disregard surroundings aesthetics when crossing the road.

In case study area, we determined number of pedestrian with Bluetooth device and analyzed pedestrian level of service according to Bureau of Public Roads (BPR) (1964) and Yuhaski and Smith (1989).

Bureau of Public Roads (BPR) (1964) model has been used by engineers for estimating travel times on road networks and determining to estimate pedestrian travel time on different walking facilities

$$t(k) = t_0 + A \cdot \left(\frac{k}{k_j} \right)^s \quad (1)$$

Where; t(k): travel time (sec) at flow level or density k, t_0: free-flow travel time (sec), k: pedestrian flow (pedestrian/m/sec) or density (pedestrian /m²), A, s: constants to be estimated in the model fitting procedure, k_j: the capacity of the pedestrian facility (pedestrian/m/sec or pedestrian /m²).
In addition that the pedestrian travel time is considered in the formulation of overall service rate and is given by Yuhaski and Smith (1989):

$$R = s\frac{1}{t(k)} = s\frac{1}{t_o - t_1} \quad (2)$$

Where; R: overall service rate of the area, s: the number of pedestrians (in the minimal length of the area), t1: time (sec.) of go in of a pedestrian in the area, t_0: time(sec.) of go out of a pedestrian from the area, t(k)=t0- t1: travel time(sec.) at density k.
We consider that level of service on this site with these formulations shown as Table 1.

3.Discussion

Baltes and Chu (2002) analyzed the pedestrian mid-block crosswalk LOS with pedestrian-vehicle interaction as the difficulty factor, based on pre-selected participants, but not using realistic pedestrian crossings. A more recent study has shown the importance of pedestrian perceived safety and road crossing difficulty with realistic pedestrian crossings at mid-block crosswalks, under mixed traffic conditions (Kadali et al. 2013; 2015). The HCM (2010) rated mid-block LOS based on the difficulty factor, but did not relate the LOS to pedestrian safety. Researchers have distinguished between marked and unmarked mid-block crosswalk LOS (Zhao, Bian, Lu, & Rong, 2014). Existing PedLOS studies have explained the factors which need to be considered for the evaluation of pedestrian sidewalks and at intersections. Studies have mainly been carried out where sidewalks were well designed foot paths of paved blocks. However, in Turkey, pedestrians may share vehicular lanes, either because of the absence of sidewalks (space is available for pedestrians, but there are no proper facilities like paving blocks or curbs for separating pedestrian and vehicular movement), or because of obstructions on the sidewalk or discontinuity of sidewalks.

There is a need to consider a wider range of factors as MAU, such as safety, design and gap opportunities, for realistic evaluation of crosswalks. No studies have been carried out on pedestrian safety using LOS as the input, and such studies are especially important at unprotected crosswalk locations under mixed traffic conditions, in order to reduce pedestrian-vehicle conflicts.

Studies have pointed out that there is no single method which can exactly capture the field Pedestrian LOS with both qualitative and quantitative parameters (Sisiopiku et al. 2007). Researchers have developed a simulation model to analyze the conditions of environments with different roadway geometries (Talevska & Todorova, 2012), but these simulation models need to be calibrated with field data and architectural elements such as urban furniture, walkway design principles and also walkway design materials. Hence, the applicability of these models to mixed traffic conditions needs further investigation for architectural design and elements.

Existing simulation models are more appropriate for evaluation of facilities with different kinds of pedestrian attributes, and different environmental, traffic, and roadway characteristics. Studies have also shown the importance of segregation of non-motorized vehicles (bicycle) from pedestrian flow (Kang et al., 2013). In this matter, walkway design is very important factor for bicycles. But again, these studies were limited to the university campus, and it does not represent either typical field conditions or heterogeneous traffic conditions and also pedestrian behavior characterisrics. Several studies have explored different modeling techniques such as linear, polynomial regression, cumulative logit models and ordered probit models, in order to quantify the effect of selected variables on Pedestrian LOS at sidewalk locations.

Researchers have explored the use of nonlinear techniques to define the Pedestrian LOS categories for the pedestrian sidewalk LOS (Sahani & Bhuyan, 2014) and these non-linear techniques are even more powerful for the evaluation of unprotected mid-block crosswalk facilities, because of pedestrian behavioral characteristics. Research using a walkability index at crosswalk locations is lacking in developing countries. This should be remedied, as the walkability index is the most appropriate measure of the accessibility of pedestrian facilities.

These studies are required because free left turn is more common in developing countries, and roundabouts are more complicated for pedestrians attempting to cross, due to the absence of adequate gaps. Pedestrian LOS combining qualitative and quantitative factors and non-compliant behavior by pedestrians at crosswalk locations has not been addressed. Furthermore, most of these studies, whether carried out at sidewalk or crosswalk, do not explain the effect of pedestrian behavioral characteristics on Pedestrian LOS under mixed traffic conditions. We are therefore exploring the establishment of threshold values for the LOS grades, and defining a new MOB, for the evaluation of unprotected mid-block crosswalk locations under mixed traffic conditions.

Crosswalks are complex, either due to pedestrian behavior or to the intersection between pedestrian and vehicle driver behavior. Using delay as a single MAU, which is the conventional approach, is suitable for crosswalk Pedestrian LOS.When pedestrians are crossing at crosswalks, they display different behavioral characteristics (rolling behavior, speed as well as path change conditions etc.) and these behavioral characteristics play a major role in pedestrian safety (Kadali & Vedagiri, 2013). In developing countries, it has been observed that drivers are unlikely to yield to pedestrians waiting at curbs. The crossing difficulty and safety varies with the pedestrian behavior and traffic and roadway characteristics, as shown in Figure 3.

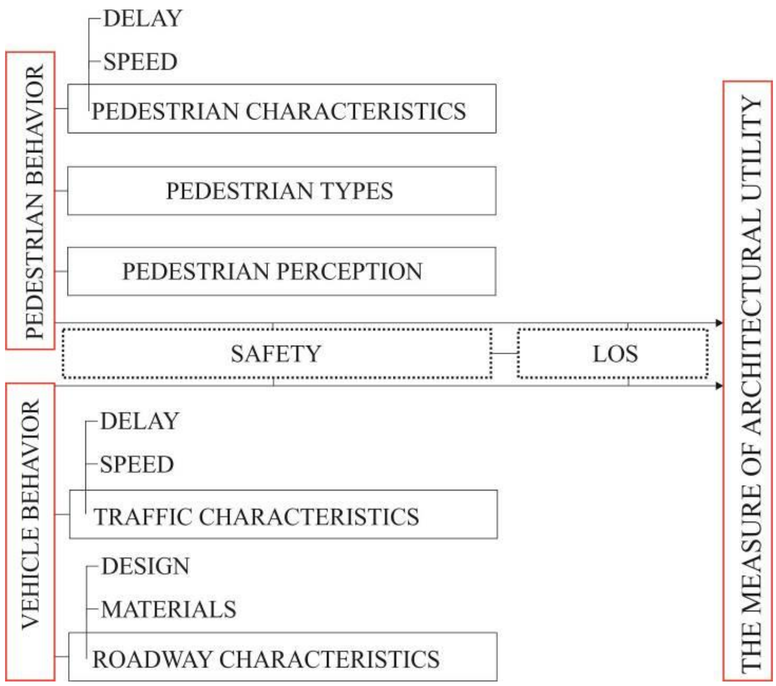

Fig. 3.
Evaluation of pedestrian LOS for MAU

In case study shows us, the difficulty, number of vehicles encountered by pedestrians while crossing and pedestrian safety should play major roles in MAU for Pedestrian LOS at unprotected mid-block crosswalk locations, alongside pedestrian delay (Kadali et al, 2015). The ease of pedestrian crossing depends upon the gap opportunities available to the pedestrian and pedestrian behavior changes with architectural elements.
The pedestrian behavioral changes while crossing depend on the interactions between pedestrians and vehicles. Furthermore, this change in pedestrian behavior may impact on pedestrian safety. The interaction between pedestrians and vehicles indirectly affects the service provided at crosswalks. So, the parameters which determine the pedestrian crosswalk LOS are mainly dependent on the behavior of the pedestrian.
However, the demographic characteristics of the pedestrian, particularly gender and age, also play a major role in both pedestrian behavioral characteristics and walking speed. So, demographic, behavioral, vehicular, traffic and roadway characteristics all need to be considered in modeling both pedestrian-vehicular interaction and safety model. These can then be incorporated into PedLOS studies at crosswalk locations. There is a need to address the pedestrian perception of delay and safety at particular crosswalks, and to develop combined models, in order to improve the quality of existing crosswalks.

3. Conclusion

Level of service is not sufficient factor for analyzing roads' safety and characteristics. Walkways, streets, roadways are most common things about analyzing road characteristics. So, "Complete Architectural Design Strategies" must a design principle by which all roadway users – motorists, bike riders, walkers, etc. – can safely move along and across a street. With road design policies like "Complete Architectural Design Strategies", bike/pedestrian-friendly roads are built routinely whenever roadwork occurs. On the other hand this paper is important for analyzing pedestrian stream with Bluetooth devices. In this sense this paper shows us that It is suggested that the analysis of motion in this way is cheap and simple.

PEDESTRIAN BEHAVIOUR ON SIDEWALKS IN VARIOUS USERS CONDICTION

Francesco Pinna[1], Francesca Farci[2], Roberto Murrau[3]
[1,2,3] *Department of Civil Engineering, Environmental and Architecture DICAAR – University of Cagliari, Cagliari Italy*

Abstract: Living in a healthy urban environment is a growing and shared need that developed a greater sensitivity about the issue of pedestrian mobility. The walking freedom can define the quality of the urban area but this freedom is conditioned by various factors. The research objective is to study pedestrian behavior on sidewalks. The study area is the city of Cagliari (Sardinia-Italy) where nine sidewalks, characterized by the presence of activities and services for citizen, are analyzed. Data are collected during on site surveys by means of concealed camcorders. For each pedestrian many factors are observed, such as gender, age, direction, distractions, transport of objects, etc.., which could influence pedestrian behaviour. Data processing allow the identification of mathematical models describing the average pedestrians behavior, subdivided for user type (isolated, single, group).In general, the mean walking pedestrian speed decreases depending on user type (in linear manner if age class grows up for isolated pedestrians while with the square of age for others users types), of gender and of facing type. Results support the idea that, to define a smooth pedestrian speed as indicator of the "walkability" of a path, in addition to considering path and users characteristics is also necessary to define the type of user for which the infrastructure is designed.

Keywords: pedestrian behaviour, pedestrian speed, sidewalk, behavioural model.

1. Introduction

Walking has always been the fundamental element of urban life and represents an effective response to some of major problems of present days, like the urban vitality loss, the pollution and the deteriorating living conditions.
When pedestrian becomes the actor of the urban scenario, significant improvements are obtained in urban quality and individual people life.
Several scientific studies investigate factors affecting pedestrian behaviour.
Willis et al (Willis 2004) consider many factors such as age, gender, level of mobility, percentage of groups, time of day, etc., finding that walking speed decreases as age increases; in fact, youngest pedestrians have the highest speeds and adults are significantly faster than elderly pedestrians, who are the slowest category.
Finnis K. K. et al (Finnis 2007) measure the mean pedestrian speed to evaluate the influences on urban planning and pedestrian facilities design in rural and urban municipalities of New Zealand. Data show complex relationships between environment, personal characteristics of pedestrians and physical factors. These factors have been taken into account during the models construction for the study of pedestrian movements.
Rahman et al (Rahaman 2012) show that in Bangladesh free flow speed is strongly influenced by pedestrians age, gender and pedestrian facilities characteristics. In addition, the presence of luggage has greater influences on female pedestrian speed, compared to the male one.
Nazir M. I. et al (Nazir 2014) study pedestrian free flow speed on sidewalks of Rajshani city, in Bangladesh. Data are collected by camcorder. The study investigates the relationship among flow, speed, density and pedestrian space. Results show that the mean walking speed is influenced by age and gender, and that locations characteristics have effects on pedestrian flows.
For this reason, also this research have the objective to investigate pedestrian infrastructure characteristics, pedestrians characteristics and the behaviour that pedestrians take along paths. This paper is the development of a previous research carried out by the authors (Murrau 2014). These knowledges could be useful factors for pedestrian spaces good design.

2. Area of study

The observed area is Cagliari city (Sardinia - Italy). Selected streets are part of the urban context and are characterized by activities and services for citizens; nine sidewalk sections are chosen in these streets.
Data are collected by field video surveys, which allow to acquire the characteristics of 4872 pedestrians.
Sidewalks general data are reported in Table 1a/b.

Table 1a
General sidewalks characteristics

Sidewalks	Width [m]	Average Walking Speed [m/s]	Standard Deviation б	Pedestrian Volume	Men [%]	Women [%]	Groups [%]
Viale Trieste	2,15	1,20	0,28	715	58,0	42,0	24,6
Via Roma	3,45	1,37	0,27	970	57,5	42,5	33,2
Via B. Rossi	1,45	1,30	0,32	194	53,6	46,4	22,5
Via Sonnino	1,35	1,17	0,28	204	49,0	51,0	35,2
Via G. Deledda	2,05	1,35	0,31	508	47,0	53,0	46,5

Table 1b
General sidewalks characteristics

Sidewalks	Width [m]	Average Walking Speed [m/s]	Standard Deviation σ	Pedestrian Volume	Men [%]	Women [%]	Groups [%]
Via Paoli sez.1	2,85	1,21	0,32	795	39,8	60,1	28,1
Via Paoli sez.2	3,95	1,17	0,40	939	38,0	62,0	30,7
Via Leopardi	2,50	1,25	0,30	280	46,0	54,0	39,8
Via M. Santo	1,30	1,30	0,33	267	46,0	54,0	26,1

All chosen sidewalks sections have LOS A, calculated by HCM method (TRB, 2010).

3. Data collection

Surveys are performed with concealed camcorder to not influence the spontaneous pedestrians behaviour. Each site is video recordered for three hours, in the shops opening hours and on days with good weather conditions. Only the two consecutive hours with the most intense pedestrian flow are considered. For each sidewalk some signs are drawn perpendicular to the path as a reference section and measured. The time taken by each pedestrian to cross the sidewalk section was defined through video processing, based on a grid of lines on the basis of the reference signs and considering that 1 movie frame corresponds to 1/25 of second. Speed is calculated from the moment where the pedestrian entered at the moment where the pedestrian left the sidewalk section of known length. For each pedestrian data are collected: gender, age, electronic devices use, bulky item carried, disability, pushchairs, direction, etc..
Pedestrians age are determined subjectively by an operator and, to reduce the error in age estimation, pedestrians are cataloged in five categories; pedestrians are also distinguished by user type in: isolated pedestrians, single pedestrians and groups. The first is a pedestrian walking alone with no one in the section, the second is a pedestrian walking alone but with others in the section and the third is a group of pedestrians walking together.

4. Data reduction

Pedestrians characterized by interference influencing their behaviour (disabilities, pushchairs, carried loads, etc..) are excluded from dataset.
Speeds analysis shows that pedestrians speeds can be approximated by a normal distribution. In fact, the area under the normal distribution graph for a distance from the mean of $\pm 3\sigma$ is 0.9973. Thus the probability that data fall within this range is 99.73% and only 0.27% of data are excluded (Montgomery 2012). This is important because the focus of the study is to determine the average pedestrian behaviour: the construction of a normal distribution of pedestrian speeds was made and data outside the range $[\mu-3\sigma; \mu+3\sigma]$ were eliminated.
Excluding data refer pedestrians with abnormal behaviour during the journey, for example people who suddenly stop and than resume walking for many reasons, joggers, runners, etc..

5. Methodology

Data are processed in order to obtain mathematical models describing the average behavior of pedestrians.
For each user type, some models are developed using multiple regression in which the dependent variable is related to independent variables by the general equation:

$$Y= \beta_0+ \beta_1 X_1+ \beta_2 X_2+ \ldots + \beta_n X_n +\varepsilon \quad (1)$$

Where; Y: is the dependent variable, $X_1,\ldots,X_n$: are independent variables, β_0: is the constant parameter (intercept), $\beta_1,\ldots, \beta_n$: are model parameters (regression coefficients), ε: is the error component in the model.
To define variables belonging to each model, the backward elimination of not significant variables (p-value>5%) are used.
The methodology used is the Cross Validation, in which a single sidewalk dataset for time are excluded; with the remaining data a behavioural model is constructed (named *partial model*); later, with the dataset excluded from the construction phase, each model is validated.
Each partial model is verified calculating the R^2 (coefficient of determination) and the RMSPE (Root mean square percent error). In the model construction phase, observed and simulated speeds have a good agreement if, graphically, data lie roughly on a 45 degree line. Later, the partial model was validated, using the sidewalk dataset excluded from the construction phase, calculating the coefficient of determination R_v^2 and $RMSPE_v$. Also in the model validation phase, observed and predicted speeds have a good agreement if, graphically, data lie roughly on a 45 degree line.
If all partial models provide good results, a global model is constructed using all sidewalks dataset and R^2 and RMSPE of this global model are calculated; also in this case, observed and predicted speeds have a good agreement if, graphically, data lie roughly on a 45 degree line.
If the global model has the same trend as partial models and partial models parameters always fall within of confidence intervals of respective global model parameters, then the partial model is considered reliable.

5.1. Variables

The speed is the variable most used in reference studies and it is the best indicator of pedestrians behaviour.
The speed is closely influenced by factors related to pedestrian and path characteristics; in particular the age is the best indicator of psycho-physical pedestrian characteristics and of his skill to walk, while the building face characterizes the path and, therefore, the environment passed through.
Dependent variables Y are:

- Y1 = mean walking speed for each age class [m/s],
- Y2 = mean walking speed for each age class according pedestrians gender [m/s].

Independent variables X_n are:

- X1= age classes for each sidewalk. The classes are: 1- From 0 to 18 years old; 2 - From 19 to 40 years old; 3 - from 41 to 65 years old; 4 - From 66 to 75 years old; 5 - Over 75 years old,
- X12= the square age classes,
- X2= the facing type: 0 - blind; 1 - accesses; 2 - shop windows,
- X3= pedestrians gender: 0 - female; 1 - male.

Also other independent variables are investigated and subsequently excluded by backward elimination like width section, effective walkway width, obstacles percentage, time of day, pedestrian flow, groups percentage, pedestrians direction.
Age class from 0 to 18 years data are present in very low percentages and therefore are excluded.

5.2. Models for isolated pedestrians

Isolated pedestrians move individually and have no interactions with other pedestrians.
By means of the multiple regression, partial models are constructed and later validated.
Two models have been identified:

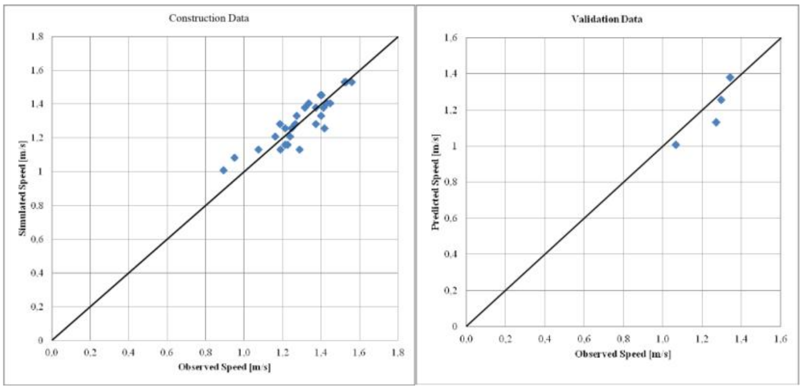
1) The mean walking speed (Y_1) is expressed as a function of age classes (X_1) and facing type (X_2),
2) The mean walking speed (Y_2) is expressed as a function of age classes (X_1), facing type (X_2) and gender (X_3).

5.2.1. Relation among mean walking speed, age classes and facing type

To better understand, results of the construction and validation phases of the partial model, obtained by excluding the sidewalk of Via Paoli sez.1, are shown as an example:

$$Y_1 = 1{,}7769 - 0{,}1237\ X_1 - 0{,}0752\ X_2 \tag{2}$$

With: R^2= 0,79; RMSPE = 0,0607. Validation phase: R^2v= 0,81; $RMSPE_v$ = 0,0652.



(1a) (1b)

Fig. 1.
Partial model excluding sidewalk of Via Paoli sez.1. Comparison between observed and estimated dataset: construction phase (1a); validation phase (1b)

Coefficients of determination and RMSPE indexes have good values, in addition observed and estimated speeds have a good agreement.
Excluding other sidewalks one at a time, similar results are obtained.
Thus, using all the sidewalks data at the same time, a global model was constructed:

$$Y_1 = 1{,}7522 - 0{,}1169\ X_1 - 0{,}0674\ X_2 \tag{3}$$

With: R^2= 0,77; RMSPE = 0,0624.

Global Model. Comparison between observed and simulated speeds

The global model has the same trend as partial models, partial models parameters always fall within of confidence intervals of respective global model parameters; coefficient of determination and RMSPE index has good value, in addition observed and estimated speeds roughly lie on a 45 degree line.

5.3. Models for single pedestrians

The single pedestrians move alone within the pedestrian flow and have interactions with other pedestrians who walk in the same or opposite direction.
By means of the multiple regression partial models are constructed and later validated.
Two models have been identified:

1) the mean walking speed (Y_1) is expressed as a function of the square of age classes (X_1) and facing type (X_2),

2) the mean walking speed (Y_2) is expressed as a function of the square of age classes (X_1), facing type (X_2) and gender (X_3).

5.3.1. Relation among mean walking speed, age classes and facing type

To better understand, results of the construction and validation phases of the partial model, obtained by excluding the sidewalk of Via Paoli sez.1, is shown as an example:

$$Y_1 = 1{,}5564 - 0{,}0167\, X_1^2 - 0{,}0909 X_2 \tag{6}$$

With: R^2= 0,76 e RMSPE= 0,0696. Validazione phase: R^2_v= 0,93 e $RMSPE_v$= 0,0354.

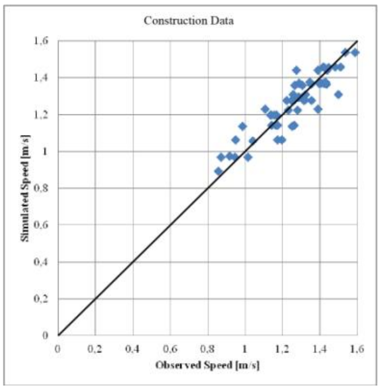

Fig. 8.
Global Model. Comparison between observed and simulated speeds

The global model has the same trend as partial models, partial models parameters always fall within of confidence intervals of respective global model parameters; coefficient of determination and RMSPE index has good value, in addition observed and estimated speeds roughly lie on a 45 degree line.

5.4. Models for groups

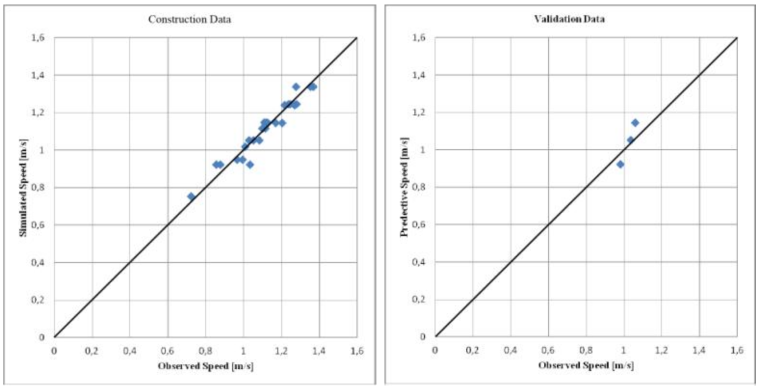
Pedestrians in group always move together with other pedestrians (one or more).
Their speeds are influenced by group size and interactions with other pedestrians constituting the pedestrian flow.
Only a model is identified; the mean walking speed (Y_1) is expressed as a function of age classes (X_1) and the facing type (X_2).
For this user type, the model expressed also as a function of gender was not good because the gender variable losts significance.

5.4.1. Relation among mean walking speed, age classes and facing type

By means of the multiple regression partial models are constructed and later validated.
To better understand, results of the construction and validation phases of the partial model, obtained by excluding the sidewalk of Via Paoli sez.1, is shown as an example:

$$Y_1 = 1{,}4124 - 0{,}0186\ X_1^2 - 0{,}0969\ X_2 \qquad (10)$$

With: R^2= 0,93 e RMSPE= 0,0375. Validation phase: R^2_v= 0,98 e $RMSPE_v$= 0,0586.



(9a) (9b)

Fig. 9.
Partial model excluding sidewalk of Via Paoli sez.1. Comparison between observed and estimated dataset: construction phase (9a); validation phase (9b)

Coefficients of determination and RMSPE indexes have good values, in addition observed and estimated speeds have a good agreement.
Excluding other sidewalks one at a time, similar results are obtained.
Thus, using all the sidewalks data at the same time, a global model was constructed:

$$Y_1 = 1{,}4042 - 0{,}0179\ X_1^{\ 2} - 0{,}0980\ X_2 \tag{11}$$

With: R^2= 0,92 e RMSPE=0,0400.

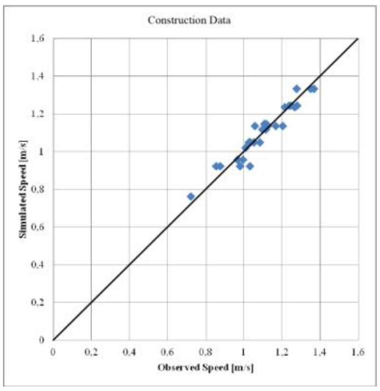

Fig. 10.
Global Model. Comparison between observed and simulated speeds

The global model has the same trend as partial models, partial models parameters always fall within of confidence intervals of respective global model parameters; coefficient of determination and RMSPE index has good value, in addition observed and estimated speeds roughly lie on a 45 degree line.

6. Conclusions

The paper purpose is to study the average pedestrians behaviour, according to pedestrians and paths characteristics. For this reason, pedestrians are subdivided into user types: isolated pedestrians, single pedestrians and groups.
For each type of user, models emphasize variations in the mean walking speed as a function of independent variables like age group, gender and facing type.
For user type "isolated pedestrians", in the first model the mean walking speed linearly decreases with increasing age class and facing type; while in the second model the mean walking speed linearly decreases with increasing age class and facing type and increases with gender.
For user type "single pedestrians", in the first model the mean walking speed decreases with square age class and facing type; while in the second model the mean walking speed decreases with square age class and facing type and grows with gender.
Only one model is found for user type "groups”; the mean walking speed decreases with square age class and facing type; no relationship is found between the mean walking speed and the gender because it loses statistical significance.
In general, the mean walking speed decreases with age classes: this confirms that with increasing age decrease psycho-physical pedestrians characteristics and therefore their walking ability.
The mean walking speed is also influenced by facing type, then the environment passed through: in fact lower speeds are obtained in presence of shops windows while higher speeds are obtained with blind overlooking; finally male pedestrians are faster than female.
The mean walking speed of “isolated pedestrians” are, generally, higher than those of “single pedestrians” and “groups”, the latter instead assume the lowest values. In “isolated pedestrians” the variable age class is in linear form, while in “single pedestrians” and “groups” is in quadratic form. This is because the "isolated pedestrians" behaviour don't suffer influences of other pedestrians, while in "single pedestrians" interactions with other pedestrians, walking in the same direction or opposite, have influences on speed and route. These influences are stronger in the “groups”. The speed of a pedestrian within a group is mainly influenced by the speed of pedestrians walking together (for this reason the gender variable loses statistical significance).
The literature, to the present day, mainly investigates the free-flow speed, ie, only isolated pedestrians, not taking into account other types of pedestrians who have more interference and influences, both with the other pedestrians and with the environment; for this reason the other types of users deserve to be more closely investigated. Such characteristics are absent in the “isolated pedestrians” but affect the other user types behaviour.
These results could improve pedestrian behaviour research and be useful to planning and design urban area, also in other cities with similar characteristics.

PEDESTRIAN CROSSING BEHAVIOUR IN MIXED TRAFFIC

Ranja Bandyopadhyaya[1], Chandan Kumar[2]
[1,2] National Institute of Technology, Patna, India

Abstract: Road crossing behaviour of pedestrians is a widely researched topic. Researchers have modelled pedestrian time gap acceptance and waiting times mostly as controlled experiments and in uniform traffic conditions. In developing countries, urban traffic comprises of motorized and non-motorized vehicles plying at widely varying speeds. Modelling pedestrian crossing behaviour in such mixed traffic conditions and also when pedestrian's mind is diverted using a mobile phone is difficult and limited research has been done in this area. In this work pedestrian crossing behaviour is studied in mixed traffic conditions for one-way traffic in the city of Patna, India using a video camera. It was observed that time gap acceptance decreases when the person is using a mobile phone while crossing. Also, pedestrians tend to cross in meandering trajectory when on mobile phone or when encountering non-motorized low speed vehicles.

Keywords: pedestrian crossing, mixed traffic, meandering crossing, crossing with phone.

1. Introduction

The road crossing behaviour of pedestrians in terms of their vehicle time gap acceptance and waiting times for different vehicle approach speeds have been widely studied by researchers.Pedestrian crossing behaviour depends on a range of factors. Researchers have tried to investigate the effect of age, gender, trip purpose, traffic speed and alertness level on crossing behaviour of pedestrians. Most of these studies have been done as controlled experiments and in uniform traffic conditions.

Holland and Hill (2007) found that women are more cautious and are less likely to cross when there is a high perception of risk than men while crossing streets.Havard& Willis (2012) observed that older pedestrians have a tendency to be more cautious than younger adults when accepting traffic gaps while crossing. They also found that the children make fewer appropriate safe crossing decisions than teenagers or adults. Similar observations were made by Bernhoft and Carstensen (2008) in a questionnaire based survey of pedestrians and cyclists in Denmark. They found that the older respondents appreciate significantly safer facilities (zebras, signalized intersections, cycle paths) than the younger respondents. They also found that younger pedestrians choose the fastest alternative while crossing, while the older road users tend to choose the safest facility and gap while crossing.

In an observational study of pedestrians performed at an unmarked roadway in China, Zhuang& Wu (2011), found that pedestrians prefer to cross a road actively in cautious ways rather than waiting passively. It may be mentioned here that in most small Indian cities pedestrians cross actively at mid block sections by waiting for acceptable gap or headway. Gastadi et al. (2015) tried to model pedestrian gap acceptance with logit and fuzzy models. Kadali &Vedagiri (2013) studied pedestrian critical gap acceptance behaviour at a six-lane, divided, mid-block section in Worli, Mumbai, India.

Many researchers have focused on studying the effect of mental alertness of pedestrians on their crossing behaviour. Haga et al. (2015) conducted a controlled experiment to examine the effect of use of smart-phone while walking . The participants texted, watched video and played games while crossing. Results showed that lack of alertness caused participants to choose lower gaps for crossing. Many similar studies (Nasar et al., 2008; Chen, 2013) show that pedestrian crossing and walking behaviour is altered and affected by the level of mental alertness.

In developing countries, the urban traffic is usually a mix of motorized vehicles like two-wheelers, cars, buses and heavy vehicles and non motorized vehicles like bicycles and rickshaws. The pedestrians while crossing the road usually encounters a number of such different types of vehicles plying at different speeds. Sometimes the pedestrian walks and crosses straight or in a weaving trajectory and sometimes runs partially through the section. Modelling pedestrian crossing behaviour in terms of gap acceptance in mixed traffic and its effect while the pedestrian's mind is diverted using a mobile phone,luggage orother heavy object is a challenging task and limited research has been done in this area. In this work pedestrian crossing behaviour is studied in mixed traffic condition for one-way traffic. An attempt is also made to study the effect of use of mobile phones on the time gap acceptance of pedestrians crossing roads having mixed traffic at different approach speeds.

The main objectives of the study are

- To check the behaviour of the pedestrian using and not using the mobile phone in mixed traffic condition for one-way traffic.
- To study the effect of use of mobile phones on the time gap acceptance of pedestrian crossing at different approach speeds and vehicle types.
- Relation between the gap acceptance, time to cross and waiting time of a pedestrian.

The nextsection details the methodology adopted for the work. Section 3 details the data and data collection techniques. Section 4 details the analysis and results and section 5 gives the major conclusions that may be drawn from the work.

2. Methodology

The overall methodology of the work can be summarized as in **Error! Reference source not found.**. The pedestrian crossing video is taken for 5 days, for 1 hour each day in the peak hour. User data of use of mobile phone, crossing speed, crossing speed range (walking slowly, normally and running), waiting time for acceptable time gap and time gap accepted are extracted manually. The vehicle stream speed and headway are also extracted. The effect of use of mobile phone on pedestrian crossing behaviour and pedestrian gap acceptance behaviour on stream speed is analyzed.

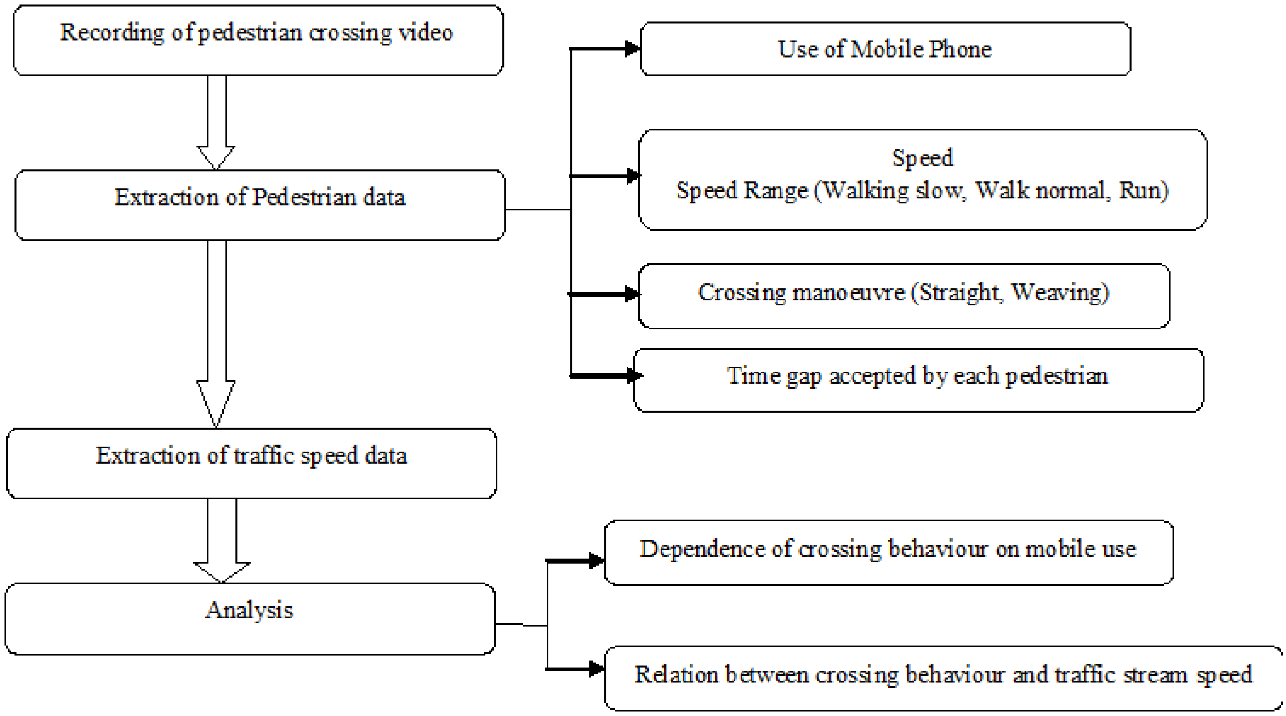

Fig. 1.
Methodology adopted for the study

3. Data

The pedestrian crossing behaviour is analysed with video data of traffic flow and pedestrian crossing through the traffic stream. The video recording is done in the Secretariat Road of Patna city, Bihar, India. The road characteristics as road width is measured manually using a tape. The road is a 4 lane divided major arterial of the Patna city carrying motorized vehicles ranging from two-wheelers and cars to buses and heavy vehicles and non-motorized vehicles like bicycles and rickshaws. The road has raised shoulders and median where pedestrians can wait for suitable gap while crossing the road. The study assumes that the pedestrian encounters traffic from only one direction. The pedestrian crosses one half of the roadand waits in the median for proper gap and crosses the other half. The width of one half of the road is 3.5 metres.

Five day 1 hour video recording of pedestrian crossing is taken during peak hour more pedestrians are crossing the road. The video is analyzed manually. The data extracted from the video recording is summarized in Table 1.

Table 1
Data Summary

SlNo.	Variable name	Unit	Min	Max	Mean	Standard Deviation
1	Waiting time	Sec	2.5	44	20	15
2	Crossing speed	m/s	0.4	1.8	0.6	0.2
3	Time gap accepted	Sec	4	16	8	1.5
4	Crossing Speed Type	Slow Walking (0.4 – 1 m/s) Walking Normally (1 – 1.5 m/s) Running (> 1.5 m/s)				
5	Use of Mobile Phone	Yes or No				
6	Crossing manoeuvre	Straight or Weaving				
7	Vehicle stream speed	m/s	8	16	12.5	2

4. Analysis & Results

The crossing behaviour is usually quantified as the time gap or time headway between two vehicles accepted by pedestrians to cross the road at mid-block sections where pedestrian crossing signals are not available. The waiting time or the time the pedestrian waits for availability of proper gap for crossing the road is also a function of the gap availability and speed of the traffic. The time gap accepted depends on the speed of the traffic stream. The crossing speed, which is another important parameter, also depends on the availability of gap and traffic speed. The crossing speed and manoeuvre depends on the mental alertness of the pedestrian and may be affected by use of mobile phone while crossing.

Initially the effect of using mobile phones on crossing behaviour of pedestrians while crossing the road actively by searching for appropriate gap is analysed. This is similar to a situation when the pedestrian is doing multiple task while crossing and is partially alert. The crossing behaviour is quantified in terms of crossing manoeuvre and crossing speed while crossing actively through traffic. The dependence of crossing behaviour of pedestrians when crossing freely and when crossing while using mobile phone is studied with chi square test of independence.

The effect of use of mobile phoneon crossing manoeuvre is a analyzed with the following two hypotheses:

Null Hypothesis H0: There is no relationship between Crossing manoeuvre and using mobile phone while crossing.

Alternative Hypothesis H1: There is a relationship between Crossing manoeuvre and using mobile phone while crossing**.**

Table 2
Use of mobile phone & crossing manoeuvre

Using mobile phone	Straight crossing	Weaving crossing
yes	169	55
no	170	840

Chi-square test of independence is done to check the hypothesis with the feedback obtained from questionnaire survey in MS EXCEL.The p-value obtained is 0.0001 which is less than the significance level of 0.05. The null hypothesis may thus be rejected.This shows that there is a significant relationship between crossing manoeuvre and carrying heavy object or mobile phone while crossing.

The effect of use of mobile phone on crossing speed is a analyzed with the following two hypotheses:

Null Hypothesis H0: There is no relationship between Crossing speed and using mobile phone while crossing.

Alternative Hypothesis H1: There is a relationship between Crossing speed and using mobile phone while crossing.

Table 3
Use of mobile phone and pedestrian crossing speed range

Pedestrian crossing speed (km/hr)		Range		
		Very slow	Walk normally	Run
Using mobile	yes	18	83	122
	no	13	60	137

Chi-square test of independence is done to check the hypothesis with the feedback obtained from questionnaire survey in MS EXCEL.The p-value obtained is 0.08 which is greater than the significance level of 0.05. The null hypothesis may thus be not being rejected.This shows that there is no significant relationship between crossing speed and using mobile phone while crossing.

Since no significant dependence could be observed between crossing speed and use of mobile phone in this study, relationship between crossing speed and choice of time gap, and relationship between crossing speed and oncoming vehicle speed are analyzed. Fig. 1. shows the relationship between crossing speed and time gap chosen for crossing. It can be observed that the crossing speed decreases with the increase of availability of time gap. This is obvious that the more the time headway available the people can walk in relaxed mode while crossing the road.

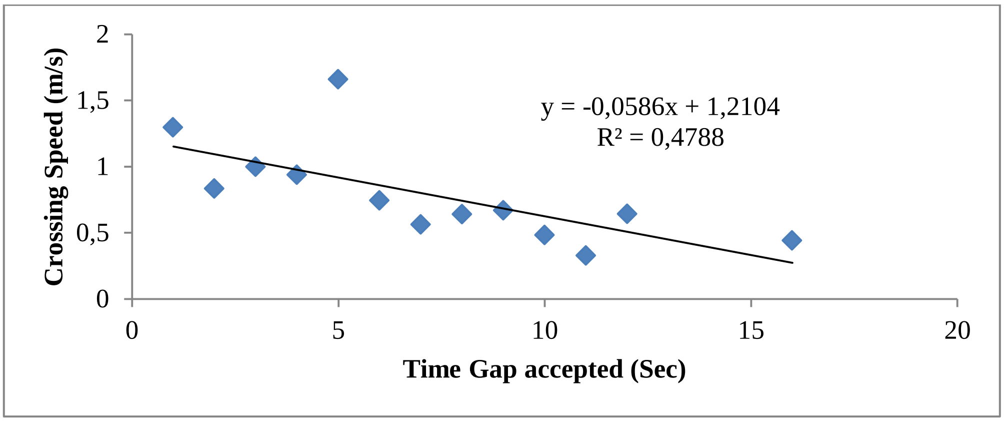

Fig. 1.
Co-relation of Time gap chosen and Crossing speed

Fig. 2. shows the relationship between crossing speed and vehicle stream speed. It can be observed that the crossing speed increases with the increase of vehicle stream speed. This is obvious that a person will speed up while crossing the road if the speed of approaching vehicles increases.

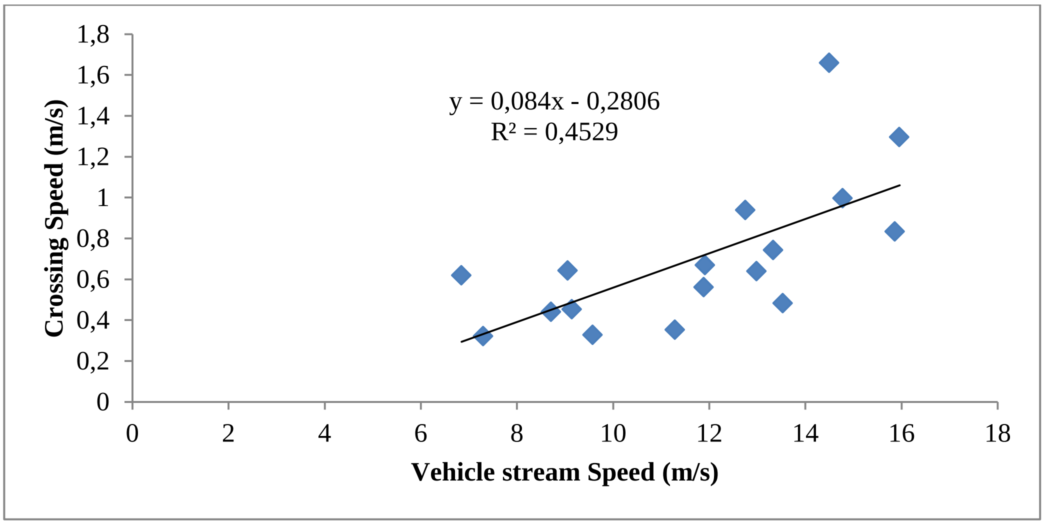

Fig. 2.
Co-relation of Vehicle stream speed and Crossing speed

Linear relationship is between crossing speed and stream speed and vehicle time gap or time headway is developed and is given in equation 1.

$$V_{Crossing} = -0.027 + 0.067V_{stream} - 0.004T_{Gap} \quad (1)$$

where,
$V_{Crossing}$ is the crossing speed in m/s
V_{stream} is the stream speed in m/s
T_{Gap} is the time gap/headway in second
The R^2 value of this regression is 0.47. The variable and their significance in the correlation is given in Table 4.

Table 4
Co-relation table of Crossing Speed regression

Variable	Coefficient	p-value
Intercept	0.27	0.95
Stream Speed (m/s)	0.067	0.07
Time headway (Gap) Sec	-0.004	0.53

It can be observed that the crossing speed is significantly dependent on the vehicle stream speed at 90% confidence limit. But, the crossing speed is not significantly dependent on the time headway available for crossing.
The variation of waiting time and the time gap or time headway accepted by pedestrian to cross is studied. Fig. 3. gives relationship between waiting time of pedestrians and the time gap available to the pedestrian for crossing the road.

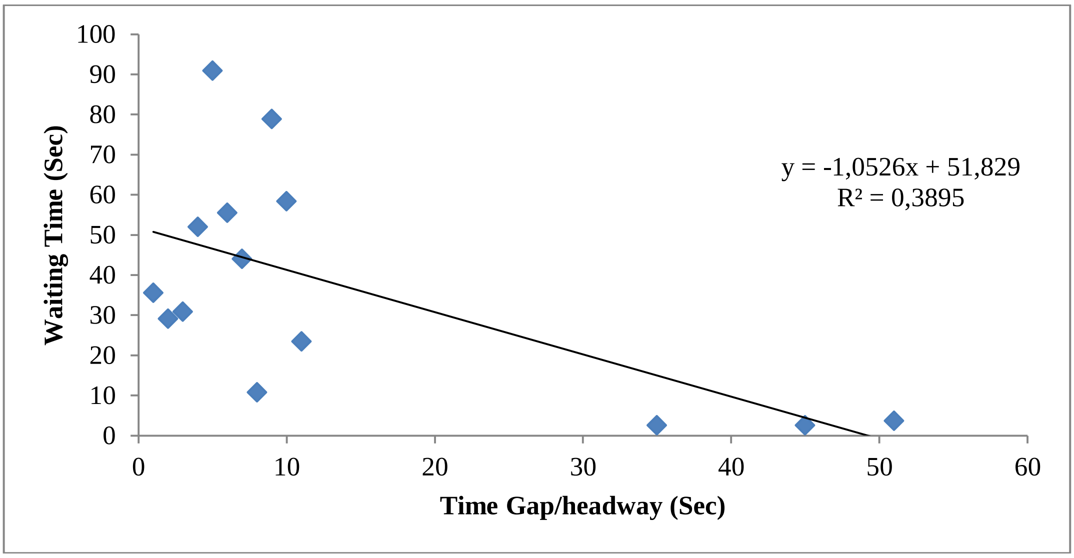

Fig. 3.
Co-relation between the waiting time & time gap accepted

It can be observed that as the time gap available to the pedestrian for crossing increases the waiting time for pedestrian for crossing the road decreases. The pedestrian can immediately start crossing the road for large time headways.
The variation of waiting time of the pedestrian to cross the road and vehicle stream speed is studied. Fig. 4. gives relationship between waiting time of pedestrians and the vehicle stream speed.

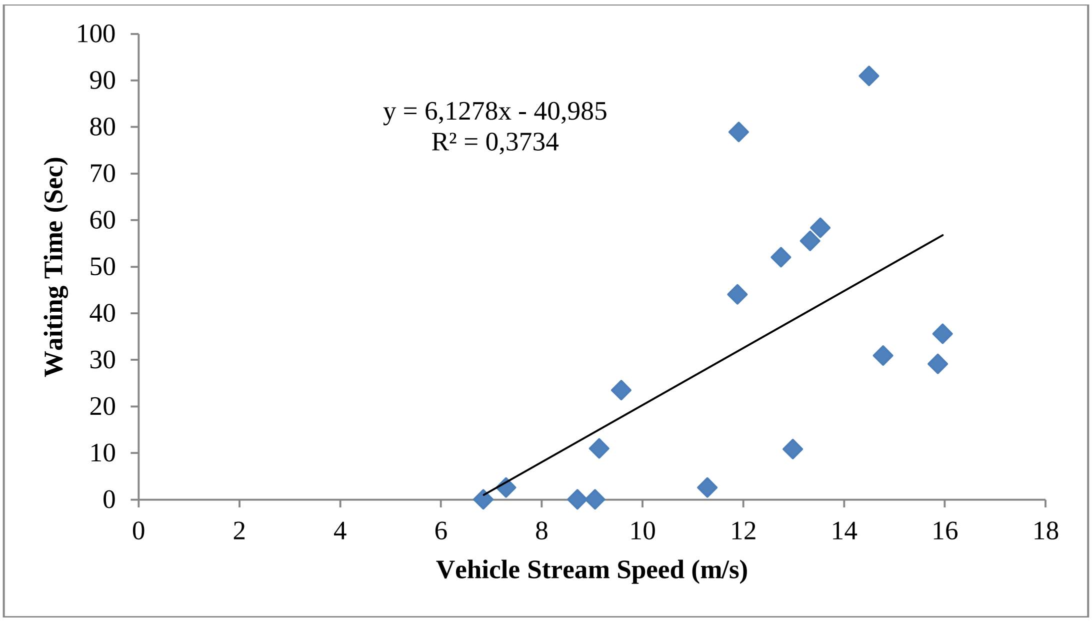

Fig. 4.
Co-relation between the waiting time & vehicle stream speed

It can be observed that as vehicle stream speed increases the waiting time for pedestrian for crossing the road increases.

5. Conclusions

The crossing behaviour is analysed in two parts. Initially, pedestrian crossing behaviour is analysed when the pedestrian is using mobile phone or carrying heavy objects. The conclusions drawn from the analysis can be summarized as:
- There is a significant relationship between crossing manoeuvre use mobile phone while crossing.
- There is no significant relationship between crossing speed of pedestrians when the pedestrian is crossing freely or is busy talking over mobile phones while crossing.

Thus, the relationship between crossing speed and traffic stream speed and relationship between time gap accepted and crossing speed is studied irrespective of the pedestrian walking free or walk while talking. The time headway accepted dependent on waiting time and vehicle speed. Thus, the variation of waiting times with time gap/headway acceptance and variation of waiting times with traffic stream speed is studied. The following conclusions may be drawn from the above study.
- The crossing speed decreases with the increase of availability of time gap. This is obvious that the more the time headway available the people can walk in relaxed mode while crossing the road.
- The crossing speed increases with the increase of vehicle stream speed. This is obvious that a person will speed up while crossing the road if the speed of approaching vehicles increases.
- The time gap available to the pedestrian for crossing increases the waiting time for pedestrian for crossing the road decreases. The pedestrian can immediately start crossing the road for large time headways.
- It can be observed that as vehicle stream speed increases the waiting time for pedestrian for crossing the road increases.

IMPACT OF ICT ON SOME SEGMENTS OF EVERYDAY LIFE OF HIGHSCHOOL POPULATION OF THE CITY OF ZAGREB

Slaven Gašparović[1]
[1] University of Zagreb, Faculty of Science, Department of Geography, Zagreb, Croatia

Abstract: Virtual mobility is defined as mobility within the virtual world which is accomplished by use of information and communication technology (ICT) in order to access certain activities without physical access that traditionally required physical access. Nowadays, young people are group of society that is most often engaged in virtual mobility and takes advantages of various opportunities that ICT provides. The paper shows that the greatest influence of ICT on the lives of high school students has on the social interactions and school activities. The aim of this paper was to investigate the impact of ICT on social interactions and school activities of high school population of the City of Zagreb. The research was conducted and analyzed using quantitative, as well as qualitative methods. The data was collected by conducting a survey on 826 high school students of the City of Zagreb. In order to make detail research of specific problems of high school population, high school students of the City of Zagreb were detiaily interviewed through eight focus groups. Thus, the results obtained from the survey were further substantiated by claims from the focus groups. The results showed significant correlation between the use of ICT and academic achievements of students. In addition, students were deeply aware of the negative impact of the internet and mobile phones usage on their school activities. Also, results showed that ICT helped in communicating with friends, but without the effect on the number of friends.

Keywords: ICT, virtual mobility, high school population, City of Zagreb.

1. Introduction

Today, young people are the group of society that is most often engaged in virtual mobility, thereby taking advantage of various opportunities provided by telecommunication and computer technology (ICT) (Livingstone, 2006; Alvarez et al., 2013). Young people use ICT technology by use of computers and mobile devices (smartphones and cell phones). Here, it should be noted that today computers and mobile phones are multi-functional as the Internet can be accessed via mobile devices (smartphones), while the former "classic" telephone conversation can be performed using a personal computer (e.g. via Skype). On the other hand, young people are transport disadvantaged social group often with limited mobility and accessibility to life activities (Gašparović, 2014; Gašparović, 2016). Therefore, young people will often use virtual mobility as a substitute for physical mobility and, under certain circumstances will reduce the impact of transport disadvantage on their everyday lives.

Croatian scientific bibliography lacks studies of interrelationship between ICT and young people thereby providing the motive for this work. Studies are mainly related to ICT as a factor of risk behavior, addiction, and violence on the Internet (e.g. Puharić et al., 2015; Mandarić, 2012; Ružić, 2011). Only rare publications address everyday life of young people (e.g. Nicodemus et al., 2014). It is important to note that there are no references regarding this subject matter on high school students.

The aim of this paper is to investigate the impact of ICT on the selected segments of high school population everyday life. The emphasis is put on the impact of ICT on the school activities of students and their social interactions. In addition, the paper studied differences in the impact of ICT on the selected segments of everyday life with regard to gender. Based on their self-assessments, the surveyed students expressed the importance of ICT in their lives. The paper presents the aspect of possible substitution of existing physical mobility for ICT and the increasing potential of ICT.

2. Theoretical framework and research methodology

Mobility can be defined from several different points of view, which results in the different types of mobility (Kenyon et al., 2002; Larsen et al., 2006). In addition to the physical movement, new types of mobility emerged and are strengthen with the development of ICT. Thus, virtual movement or virtual mobility gained on the significance. Virtual mobility is a movement in the virtual world that is realized in the context of telecommunication and computer technologies. Therefore, virtual mobility is about accessing to certain activities that traditionally required physical access, which can now be performed without physical access. This is very important issue because virtual mobility overcomes geographical and social distance in real time. Virtual mobility is strongly linked to the extreme expansion of the Internet and mobile telecommunication, completely changing the human race. Therefore, virtual mobility includes, among other things, teleworking, creating new and maintaining existing social connections (especially via the social media, e-mails and personal web pages), gaining both formal and informal education, shopping via the Internet etc. If the physical mobility is hampered or disabled for some reason, in certain circumstances virtual mobility may be used as its substitute (Kenyon et al., 2002; Larsen et al., 2006).

International scientific bibliography is extremely rich in studies about the relationship between ICT and young people. However, not so many articles concerning the high school population can be found. Also, there are only few papers describing the impact of ICT on school activities of students. The link between ICT and school activities is studied mainly from the aspect of Internet addiction and its impact on childrens' education. Further, Internet addiction was

[1] Corresponding author: slaveng@geog.pmf.hr

associated with problems in learning and school success (e.g. Siomos et al., 2013; Zhu et al., 2015; Soohyun, 2011). Badasyan and Silva (2012) have concluded that the possibility to access the Internet affected good school achievement, while Adegoke (2013) and Darah (2013) concluded that Internet access had no effect on school performance. Austin and Totaro (2011) have concluded that excessive use of the Internet adversely affected school performance. Young people use the Internet for a whole range of activities. Among the most common reasons for Internet usage are school activities and games (Omar et al., 2014; Lee and Chae, 2007). A whole range of authors emphasized communication (i.e. instant messaging and social networking) as an important reason for Internet usage (Paus-Hasebrink et al., 2010). Studies of numerous authors put the emphasis on social media usage (e.g. Woods et al., 2016; Montgomery, 2015; Barbieri, et al., 2016). The impact of mobile phones is also mentioned in both, positive and negative context. Seo et al. (2016) state that mobile phones are used for assistance in school activities, while Abeele et al. (2014) consider it as an important tool for social networking. However, many authors emphasize negative aspects of mobile phone usage, such as addiction, attention deficit, depression and so (e.g. Billieux, 2012; Lee et al., 2014), which may adversely affect the school and other activities.

In this study survey and interview methods were used. Anonymous and completely voluntary survey was conducted in seven high schools in the City of Zagreb. A total of 826 students were surveyed (3% of the total high school population in the City of Zagreb). Gender ratio in the survey included 429 females (51.9%) and 397 males (48.1%). The survey obtained general information about the participants and their attitudes and opinions towards ICT and its impact on their everyday lives. Students were also asked to give their opinions about eight suggested transport (virtual mobility) issues, according to the Likert scale, in which each issue was assessed from 1 to 5 indicating their importance for the student (on the scale: 1 – no importance/very little importance; 5 – very high importance).

In order to obtain detailed information on the researched issues, focus group method was included to the research. The focus group research was conducted in two high schools in the City of Zagreb. In each school students were divided into four groups based on their age and gender. Group I included female students of the 1st and 2nd grades, Group II male students of the 1st and 2nd grades, Group III female students of the 3rd and 4th grades, and Group IV male students of the 3rd and 4th grades. In total 8 focus groups were examined. Within each group, there was an evident dichotomy among the students with regard to their place of residence (half of the students lived near the city center and half lived nearer to the city periphery).

The research was conducted according to the *Code of Ethics of Research with Children* (2003). Permission for the research was obtained from the Ministry of Science, Education and Sport of the Republic of Croatia, the Principal of each school and pupils' parents. The data collected in the survey were processed using the software package SPSS Statistics 20.0 using the statistical correlation method and t-test.

3. Impact of ICT on some segments of everyday life of high school population

Computer technology is very widespread among young people. This is confirmed by the fact that 99% of surveyed students (818 of 826 students) in this study used a computer at home. Students used laptops and desktops almost equally, 51.5% students (421) used laptop, while used 48.5% students (397) use desktop computer. Only 1% of students (8) did not use computer at home, for being used by other family members (7 students) or not owning one (only one student). Further, the vast majority of students accessed Internet via computers at a flat rate (89%, 735 students), while 7.6% (63 students) accessed Internet with limited data traffic. Only 3.4% of students (28) did not have Internet access at home. Still, out of this 3.4%, 9 of them had possibility to access it regularly elsewhere, while 10 students had possibility to access it occasionally elsewhere. Only 9 students lacked the possibility to access Internet at home, and did not have the possibility to access it elsewhere.

Beside computer technology, mobile technology increasingly takes place in the everyday lives of young people. Thus 99.3% of students use mobile phone (820 of 826 surveyed students). 3/4 of students use a smartphone (76.7% or 629 students), while 191 of them (23.3%) use a cell phone. Only 6 students don't use a mobile phone (0.7% of the surveyed students). It should be noted that 764 students use the Internet via mobile phone (92.5% of students), while only 7.5% (62 students) students don't use it. 545 students (71.3%) use mobile Internet regularly, occasionally 166 students (21.7%), and when it is absolutely necessary 53 students (7.0%).

Numerous studies tried to determine the extent of internet usage among the students. These estimates varied in dependence of the method used for Internet usage measurement (e.g. on the basis of personal statements or automatic recording), the age of examined children and definition of "Internet usage" (e.g. time spent or frequency of use). Studies reported that young people use the Internet on average for 1 to 3 hours daily (Jackson et al., 2006; Alvarez et al., 2013). Researchers agree that children today spend a considerable amount of time using the Internet (Jackson et al., 2006; Livingstone et al., 2011; Özgür, 2016).

Due to the growing importance of the Internet in everyday life of students, which is accessed either by computers or mobile phones, the time spent on the Internet is even higher than previous reports suggest. The results showed that high school students spend 4.3 hours on the Internet on average daily (including the usage of virtual social networks). Interestingly, there was no statistically significant correlation between age and time spent on the Internet, while the slight statistically significant correlation occurred with regard to gender ($r = .117$, $p<0.01$), which was confirmed by t-test ($t = -3.389$; $p<0.01$). These results indicated that girls spend more time on the Internet than boys.Furthermore, reasons for using the Internet had to be established. Studies have shown that young people use the Internet mostly for school activities (information, homework, school projects) and communication with friends (via email and chat) (Jackson et al., 2006). Although these were recent researches, today there are other reasons for the use the Internet.

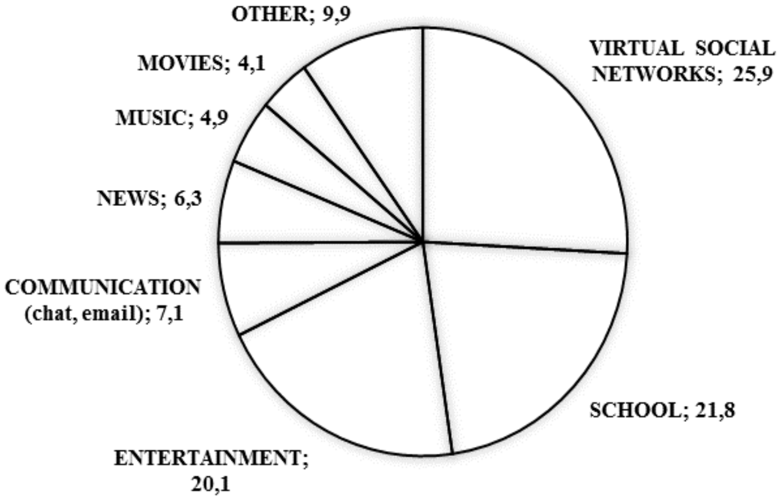

Fig. 1.
The purpose of Internet usage of high school population in the City of Zagreb (in %)
Source: Survey

Figure 1 shows the purpose of Internet usage among high school students in the City of Zagreb. The research showed that the first reason to use the Internet was communication via social media (primarily Facebook), and not via chat or e-mail. The second reason to use the Internet was for school activities (various information, help with writing homework, reports and seminar papers etc.). In addition, the Internet was also used for entertainment for accessing YouTube, games and various other forms of entertainment. Communication via chat and e-mail and other channels (except via social networks) was also popular. Beside access to services that provide various news, the Internet was used to listen and download music and movies. Also there were various other reasons such as browsing transport timetables, on-line betting, writing blogs etc.

As founded, ICT was highly present in everyday lives of students. Therefore, it can be assumed that this technology affects their everyday lives. Almost 90% of students (87.5%) stated that the Internet and mobile phones affected the organization of their everyday life (Table 1). This point was relatively important, as one third of students (34%) stated that ICT often or almost always (i.e. high or very high) affected the organization of everyday life. If students who stated that ICT occasionally (i.e. moderate) affected organization of everyday life are added, then the share of students stating that ICT had influenced their life went up to 71.2%. Only less than one third of students (28.8%) stated that ICT rare (i.e. poor) affected the organization of everyday life.

Table 1
Frequency and strength of the influence of ICT on everyday lives of high school students in the City of Zagreb

Frequency/strength of the influence	Number of students	Share (in %)
Influence	723	87.5
rare / poor	*208*	*28.8*
occasionally / moderate	*269*	*37.2*
often / high	*163*	*22.5*
almost always / very high	*83*	*11.5*
No influence	103	12.5
Total	826	100

Source: Survey

In addition to investigate the presence of ICT in the lives of high school students, the aim was to examine the importance of individual segments of ICT in their everyday lives. In order to examine this issue, the method of self-reported measure was applied. In this process, eight suggested transport (virtual mobility) issues i.e. problems were assessed from the aspect of importance to provide possible impact on students' daily life. Given that students everyday life is different in many aspects, especially in the context of gender and age, it was assumed that there were differences in the importance of the problems. A Likert scale of self-assessment was used in which the students assessed suggested issues. To determine the correlation between age/gender and importance of the issues Pearson correlation coefficient and point-biserial correlation coefficient were used. (Table 2).

Table 2
Correlation of age and gender with the importance of virtual mobility issues

Issue		Age		Gender
Ability to access to Internet whenever you want to	r	-.059	r_{pb}	**.114****
	p	.092	p	.001
Constant and quick access to information via the Internet	r	-.006	r_{pb}	**.128****
	p	.863	p	.000
High speed of "fix" Internet	r	.003	r_{pb}	**.075***
	p	.941	p	.030

Access to virtual social media (e.g. Facebook, Twitter...)	r	**-.118****	r_{pb}	**.230****
	p	.001	p	.000
Feeling safe when using the Internet	r	-.056	r_{pb}	**.256****
	p	.105	p	.000
The possibility of permanent availability via mobile phones and the Internet	r	-.052	r_{pb}	**.218****
	p	.135	p	.000
Covering Internet and mobile phone costs	r	-.011	r_{pb}	**.145****
	p	.763	p	.000

r = Pearson's correlation coefficient; r_{pb} = point-biserial correlation coefficient; p = statistical significance
* $p<0.05$; ** $p<0.01$
Source: Survey

Based on the data shown, it could be assumed that the association between gender and issues was stronger than the association between age and issues. A statistically significant correlation between age and transport issues appeared only in two cases. The obtained results clearly indicate a statistically significant correlation, though low, between gender and issues. This correlation was significant for all issues. It is necessary to note that in all cases, girls gave higher grades to issues than boys did, which might indicate that girls find the proposed issues more important in their daily lives than boys do.

In order to detaily examine the differences between girls and boys within the frame of certain issues, the statistical significance of differences between male and female subjects for a series of test variables was tested using a t-test (Table 3). Though these were not exceptionally large differences in the grade assigned, the t-test indicated that there was a statistically significant difference in the responses between girls and boys. The obtained results were in line with the correlation results. The results of the t-test suggested that girls gave higher grades for transport issues from the aspect of importance in their daily lives. Although the differences between girls and boys were not so pronounced, it can be noted that girls gave higher importance to the access to virtual social networks, to the importance of security when using the Internet, as well as to the importance of high-speed mobile Internet and the possibilities for permanent availability. Such results could indicate a higher importance of virtual mobility in the daily life for girls than for boys.

Table 3
Mean values for the results of assessing the influence of issues on the daily life of high school students and the values of t-test

Issue	M_M	M_F	t	p
Ability to access to Internet whenever you want to	3.77	4.08	**-3.744***	.000
Constant and quick access to information via the Internet	3.79	4.11	**-3.962***	.000
High speed of ''fix'' Internet	3.83	4.04	**-2.524***	.012
High speed of mobile Internet	3.56	4.09	**-6.302***	.000
Access to virtual social media (e.g. Facebook, Twitter...)	3.26	3.88	**-7.034***	.000
Safety when using the Internet	3.20	3.91	**-7.887***	.000
The possibility of permanent availability via mobile phones and the Internet	3.59	4.14	**-6.659***	.000
Covering Internet and mobile phone costs	3.15	3.54	**-4.490***	.000

Source: Survey

The impact of ICT on the organization of daily life will be mainly manifested in its two segments. In accordance with the results of the reasons for using the Internet, the impact was most prominent in communication with friends and within the school activities.

Friendship is very important component of young peoples' life. They establish and maintain as many friendships as possible, and these friendships tend to have longer duration compared to those from childhood. High school students have more friends than adults and communicate with them more than adults (Boneva et al., 2006). This communication is carried out in the context of physical meetings, but also through virtual mobility, of which the most important channels of communication are through mobile phones and virtual social networks accessed via computers, but also mobile phones. Still, some studies have shown that the need for intensive communication decreases from adolescence to adulthood with regard to increasing stability of personal identity. For example, older teens have less friends than younger teens (Boneva et al., 2006). This is also shown by the data, which showed that the number of good friends of high school students from Zagreb slowly decreased with age. This proves the correlation coefficient ($r = -.074$, $p<0.05$), indicating a slight, but statistically significant correlation.

In the context of social interactions, a great majority of high school students was using ICT for the formation of new relationships, as well as to maintain existing friendships. Young people are keeping their social life during adolescence through both, physical and virtual meetings (Mesch, 2009). This was certainly confirmed by the survey of high school students in Zagreb. It should be noted that ICT had more significance in the frequency of communication with good friends as more than half of the surveyed students (58.7%) communicated in this way very often with good friends (i.e. every day). Unlike virtual meetings, 48.7% of high school students communicate very often (i.e. every day) with their good friends through physical companionship. It can be seen that good friends of high school students are people who do not necessarily go with them in the same class or even in the same school since students communicate with them often (i.e. a few times a week) through physical meetings (41.9%) indicating a temporary meetings during the week or evening outings on weekends. This was also evidenced by the frequent communications (i.e. a few times a week) with good friends via the Internet and mobile phones which accounted for 31.4%, being ten percent less than the physical companionship. Finally, it can be concluded that friendship had a very great importance in the lives of high school students as they communicated with their close friends very often, while emphasis is put on the communication via the Internet and mobile technology rather than to the physical companionship. This allowed communication with friends with whom it was not possible to physically meet on daily basis, partly overcoming the physical distance between them.

Table 4
Frequency of the communication with good friends

Frequency	Physical companionship		ICT	
	Number	Share (in %)	Number	Share (in %)
Never	4	0.4	6	0.7
Rare (several times a year)	13	1.6	17	2.1
Occasionally (several times a month)	61	7.4	59	7.1
Often (several times a week)	346	41.9	259	31.4
Always (every day)	402	48.7	485	58.7
Total	826	100	826	100

Source: Survey

When analyzing the importance of ICT in establishing new and maintaining existing social interactions, it can be asked if the usage of ICT affected the number of friends. In fact, some research had shown that teens who spend lots of time on the Internet, had less social contact with family and friends in comparison to those who use it less (e.g. Kraut et al., 1998). In contrast, other studies had found that youth increase their social interaction just by using the Internet (e.g. the Pew Internet and American Life Project, 2002). Analysis of this issue in the City of Zagreb showed that the frequency of using ICT had no connections with a number of good friends. Correlation analysis showed statistically insignificant correlation between the time spent on the Internet and the number of close friends ($r = .041$; $p>0.05$), and between the time spent on virtual social networks and the number of good friends ($r = .051$, $p>0.05$). Students stated that the Internet and mobile phones helped in communicating with friends, with no effect on the number of friends.

- *Number of friends does not depend on the mobile phone and the Internet. We would hang out with them one way or another.*
  (female student, 17 years, Trešnjevka)
- *I think I would have the same number of friends. They are friends from my childhood and from elementary school.*
  (male student, 17 years, Centar)
- *I think it does not affect the number of friends. I see my friends every day and because of mobile phones we talk even more. It is better for us because we could see and hear each other.*
  (female student, 16 years, Botinec)
- *I think I even meet my friends more often because of mobile phones. We make a deal via mobile phone and then meet.*
  (male student, 18 years, Malešnica)

However, there are also students who feel that ICT influence the friendship in the context of reduced mutual physical meetings.

- *I think I see some of my friends less because they are affected by this.*
  (male student, 16 years, Jarun)

Despite the fact that students consider ICT useful for socializing with friends, some students think that quality of physical meetings declined because of ICT.

- *Typing the mobile phone when you're having coffee… What's the point at all to see anyone if they are all using the mobile phone.*
  (male student, 17 years, Centre)
- *I am totally irritated when I am with friends and when people do not communicate but are constantly on the phone. I find that stupid. If you are with a person then rather talk to him/her or him and socialize, and not to check Instagram, Facebook etc. All that can wait.*
  (female student, 16 years, Botinec)
- *People lose confidence. It is easier to communicate via mobile phones and other applications, and when we meet face to face there is eerie silence.*
  (female student, 14 years, Trešnjevka)

As the virtual social networks are extremely important element in communicating with friends, and considering that the usage of virtual social networks is the most important reason for using the Internet, usage of virtual social networks was additionally examined. Thus, 95.4% of students (788 of them) used virtual social networks to some extent, while only 4.6% (38 of students) did not use them. The significance of virtual social networks in the daily lives of high school students was extremely high as shown by the average time of their use that was 2.6 hours per day, being 60% of the total time spent on the Internet. Thereat, girls used virtual social networks more than boys, confirmed by the correlation coefficient ($r = .241$, $p<0.01$), indicating a statistically significant correlation. This result was confirmed by the t-test ($t = -6.965$, $p<0.01$). It could be assumed that social interaction was more important in life for girls than for boys. This was also indicated by the correlation between frequency of communication with good friends via the Internet and mobile phones and gender in favor of girls ($r = .196$, $p<0.01$). This was a slight correlation, but statistically significant and obviously systemically present, which was also confirmed by the t-test ($t = -5.741$; $p<0.01$). Greater importance of social interaction for girls was indicated by the correlation between frequency of communication with good friends via physical meetings and gender, being in favor of girls ($r = .142$, $p<0.01$); here a slight, but statistically significant correlation was present ($t = -4.105$; $p<0.01$).

Impact of ICT on school activities was certainly expected, as this was an activity that all students were regularly engaged every day. For this purpose, students' attitudes related to the impact of ICT on school activities were examined (Table 5). Interestingly, more than two-thirds of students (76.2%) stated that ICT affected their school activities. This indicated the great importance of ICT in their everyday life. Thereby, ICT had quite a significant impact on school activities of students. Namely, 43.6% of students stated that ICT often or almost always (i.e. high or very high) affected their school activities. In addition to students who stated that ICT occasionally (i.e. moderate) influences (37.8% of students), then the share was rather high 81.4%. Only less than a fifth of students (18.6%) stated that ICT rare (i.e. poor) affected the school activities.

Table 5

Frequency and strength of the influence of ICT on the school activities of high school students in the City of Zagreb

Frequency/strength of the influence	Number of students	Share (in %)
Influence	629	76.2
rare / poor	*117*	*18.6*
occasionally / moderate	*238*	*37.8*
often / high	*200*	*31.8*
almost always / very high	*74*	*11.8*
No influence	197	23.8
Total	826	100

Source: Survey

Table 6

Ways in which ICT impacts the school activities of students

Way of influence	Number of students	Share (in %)
Help in performing school activities	287	45.6
Negative impact on performance of school activities	342	54.4
Total	629	100

Source: Survey

Impact of ICT on school activities of students was reflected through two segments (Table 6). Students stated that ICT helped in performing their school activities (45.6%). This assistance was evident in several aspects. Students stated that ICT allowed access to additional information for the courses. In addition, ICT allowed communication with each other (via e.g. social networks, emails, SMSs etc.) based on which students shared information about curricula and different information related to school activities. It is interesting to point out how students used ICT for illegal acts related to school activities. It was about a use of ICT in writing exams within the illicit use, as well as the taking photos of exams and sharing them later.

- *I think it has more positive than negative effect. We can check an exam or reading, we do not have to go to friend to look at it. We send in via the Internet.*
  (male student, 16 years, Medveščak)
- *On Facebook we have a group, called the 2d, where you put some questions, sub-questions, "... let me get this ...", "... can you help me ...", I think that it is much more useful than look it up in the book and wasting time.*
  (female student, 16 years, Pantovčak)
- *It is easier to find help. When we went to the elementary school we all lived close to each other, now that we're in the secondary a lot of people do not live close to each other and it is easier for lot of us, we do not have to travel to each other.*
  (female student, 16 years, Botinec)
- *It is easier for us to reach some data, for example for Croatian language, reading, mathematics where we have a page with solutions so we can check our homework.*
  (female student, 18 years, Špansko)
- *ICT helps. In order not to learn everything from books, we take photos of some scripts. It serves as a source of knowledge, all can be found on the Internet.*
  (male student, 18 years, Centar)
- *During the Latin language, many times it helped me to get the translation of the text, I just take a photo and choose to "translate" the Croatian and it translate it more or less accurately.*
  (male student, 15 years old, Kustošija)

Apart from help in performing the school obligations, students stated that ICT had negative impact on their school activities. It is interesting that the proportion of students with such an attitude was more than half of respondents (54.4%). The students thought that Internet and mobile phones distracted from the learning, so it sometimes even threated in certain subjects.

- *It affects by the time spend on the Internet. It can be quite addictive.*
  [Do you think you learn less?]
  Yes. I'm aware of that, but I cannot help myself.
  (male student, 16 years, Centar)
- *It influences negatively, when I have to learn, I'm on the phone for an hour, sitting beside a book and then the time pass in doing nothing, I don't learn and get negative mark.*
  [Are you aware of the problem?]
  I am aware of the problem, but cannot give up '.
  [Why?]
  I do not know. I have no motivation regardless of grades. When I leave it, every five minutes I go and check it for if there's something new, and always like that.
  (male student, 16 years, Vrapče)
- *I understand that this is not good and that I am addicted to these social networks but I don't do anything to reduce it. I am aware that my school activities suffer because of it.*
  (female student, 18 years, Lučko)
- *It affects when we learn. And if there is nothing on Facebook I still have to go on Facebook because I do not want to learn, so I rather go to Facebook.*
  (female student, 15 years, Savica)
- *ICT threatens us. If we didn't have a mobile phone and the Internet and Facebook we could learn more.*
  (female student, 18 years, Jarun)

Beside the students' opinion that ICT affects their school activities both, positively and negatively, their school success to some extent depends on ICT technology. Namely, after analyzing the correlation between school success and ICT a slight correlation was observed between the time spent on the Internet and school success. This was a statistically significant correlation ($r = -.099$, $p<0.01$), indicating a poorer school success of students with the increase in time spent on the Internet. Also, a slight, though statistically significant correlation occurred between the variables of school success and time spent on social networks ($r = -.084$, $p<0.05$).

In order to confirm obtained results, the time spent on the Internet and social media were placed in tabular correlation with school success (Table 7). Thereby, time spent on the Internet and social media were divided into classes. This analysis showed that decrease in school success was related to the increase in time spent on the Internet and social media. However, the value of school success was not reduced substantially, therefore the difference in the school success of high school students who spent more and less time on the Internet and social media was relatively slight.

Table 7
Relation between time spent on the Internet, social media and school success

Time (in hours)	School success (in the case of the Internet)	School success (in the case of the social media)
0 – 2.9	3.96	3.95
3 – 5.9	3.95	3.89
6 – 8.9	3.80	3.88
> 9	3.76	3.81

Source: Survey

It can be concluded that in the domain of school success the time spent on the Internet and on social media had slight impact. Certainly, it should be investigated in which segment of cognitive skills ICT eventually had more significant impact. Given the scope and complexity of such research, it is certainly a separate research topic.

In the context of the spatial segment of research, the correlation between the location of the student's residence and the use of ICT were examined. This study was conducted at the schools in the city center. This means that students who spend more time on the traveling to school live closer to the city periphery. But statistically significant correlation between travel time to school and time spent on the Internet and social media was not found ($r = .005$; $p>0.05$; $r = .043$; $p>0.05$). These results were also confirmed by students.

- *It doesn't matter where someone lives. While I am in the bus to school or from school I use the Internet or I chat with my friends who are already at home. And they are also at home using the Internet. I think we spend the time on the Internet equally.*
  (female student, 16 years, Botinec)
- *I think that we use the Internet equally. We use the Internet, social networks, mobile phones, there is no correlation with living location.*
  (male student, 18 years, Centar)
- *We use the Internet and social media when we need and when we want, no matter where we live.*
  (male student, 16 years, Medveščak)

4. Conclusion

The results showed that ICT usage was very much present in the everyday lives of students. The possession and use of ICT increases the mobility of young people. They use ICT mainly to communicate with friends, especially via virtual social media, and in the context of school activities (getting information, assistance in writing homework, reports and seminar papers). The results showed that ICT helped in communicating with friends, but with no effect to the number of friends. Analysis showed the decrease in school success related to the increase in time spent on the Internet and social media, though the correlation between ICT usage and school success is relatively slight. It should be noted that students were deeply aware of the disadvantages of Internet and mobile phones usage in the context of neglecting their duties. Obtained results could indicate a higher importance of virtual mobility in the daily life for girls than for boys.

High school population are the group of society that is most often engaged in virtual mobility. This work showed that ICT has an impact on some segments of their lives. Since there are not so many papers that study the impact of ICT on lives of high school students, certainly it would be good to broaden researches on various segments of their lives.

THE IMPACT OF PUBLIC DATA AVAILABLE FROM SOCIAL NETWORKS ON AIR TRAFFIC SECURITY AND SAFETY

Dušan Crnogorac[1], Svetlana Čičević[2]
[1,2] University of Belgrade, Faculty for Transport and Traffic Engineering, Belgrade, Serbia

Abstract: Recent events regarding air traffic and transport (such as terrorist attacks) indicated the necessity to explore crew publicly available data from social networks. The main purpose of this research is to increase awareness of air traffic and security companies, to the risks of publicly available data and emphasize the threat to public safety. The sample included identification of pilots and co-pilots in selected airlines. Starting from public profile available on a business network, the search was performed trough all other social network sites where the employee had or could have personal data. The findings from this research suggest that air traffic and transport companies involved have to increase alertness level as well as to educate their employees on the risks of disclosing private information. This knowledge could make a significant contribution to air transport and traffic security and safety.

Keywords: air traffic, social network, public data, pilot, aircraft, airline, terrorist, aircraft security.

1. Introduction

Air traffic and transport has always been a convenient target for terrorist groups. While airports, airlines, and Air traffic control information technology systems have been identified as critical transportation infrastructure, currently, a growing threat to the safety and security of the global aviation system, as one of the most complex and integrated systems of information and communications technology, lies in cyberspace. The high degree of interconnectivity and access by employees and airspace users, to enterprise networks, is expected to achieve efficiencies, improve system performance and productivity, and increase safety through automation. While the benefits have been enormous, at the same time, creates significant inherent security vulnerabilities, making it a potential target for a large-scale cyber attacks.

Cybersecurity relies on technology, operations, and people. Notwithstanding an essential element of cybersecurity has always been the human portion of the triangle (von Solms & Warren, 2011), an acute shortage of comprehensive scientific literature upon it is evident. Nevertheless, several references could be extracted recognizing the potential issues related to the topic of awareness of cybersecurity threats posed by employees' inappropriate usage of Social Network Sites (SNS) for aviation system safety.

Airplanes have limited resources to conduct a safe landing. Every flight is time limited and it involves many people. Last airport attacks increased the level of airport safety and security (AIAA Decision Paper, 2013, Jeyakodi, 2015).

Despite the fact that Aviation is a unique critical national infrastructure that requires the application of higher standards of security to fortify their systems from cyber-attacks, till now, there is no single comprehensive approach to cyber security in civil aviation. Cyber standards, security and enforcement are still in their nascent stages.

The first step resolving such situation would be to see the complete picture by assessment of the spectrum of these new and emerging threats, in order to properly understand, identify and accept their existence, and coherently deal with the risks to people, institutions, and the economy (Mueller and Stewart, 2011). Moreover, a cyber security culture must be established.

Thus, the main purpose of this study was to show how easy is to gather the extensive amount of Personally Identifiable Information about pilots and co-pilots, working for two airlines, that are freely available through various social network sites and generally accessible, which makes them easy to locate either on-line or off-line. Further, the objective was to provide an overview of the measures and strategies to mitigate cyber risks associated with the critical personal information available.

1.1. Social network sites and aviation cyber – security

Social media (SM) has permeated every aspect of society. Social networks are dedicated websites or other application that connect people and enables them to communicate with each other by posting messages, comments, images etc. Social networks connect people at low cost and this is the main reason for such a wide usage. There are more than two hundred known social networks. At their early beginnings, SNS started to make contacts with people and build a network of healthy relationship in the society.

But due to the overwhelming amount of information generated, exchanged, and redistributed by users, now it seems they became an easy way for confidential personal information to be accidentally or deliberately exposed. Representing a new range of online uses, they pose a series of challenges to the security community, offering cybercriminals a great advantage to target victims. Thus, the adoption of new tools and techniques to search, analyze and secure online data is demanded.

Social networks (SN) have changed the ways in which users interact, share information (personal data, opinions, news), and conduct business on-line, transforming the familiar communication-focused Internet into a new social platform. Because SNS enable users to articulate and make visible their social networks, the public display of connections is a

[1]Corresponding author: crni@sf.bg.ac.rs

crucial component of these services. The ability to share different social information with different groups is a key characteristic of social identities.

Every day millions of people around the world post messages via social media in order to share thoughts, ideas, strategies, resources. These technologies generate an enormous amount of data, from which we can obtain valuable information for different purposes, from the emergency management to the intelligence (Cresci et al, 2016).

People of all ages, around the world, knowingly and willingly use Facebook, Twitter, LinkedIn, Match.com, Friendster, or MySpace, as one of still usable network for gathering information, as well as hundred other sites to communicate, find friends, dates, and jobs – and in doing so, they wittingly reveal highly personal information to friends, as well as strangers.

A cyber-terrorist may hack into critical infrastructure in an attempt to cause grave harm such as loss of life or significant economic damage. Such attacks are aimed at wreaking havoc on information technology systems that are an integral part of public safety, traffic control, medical and emergency services, and public works (Maras, 2012).

In the decade since its inception, social media, such as LinkedIn, Twitter, Facebook, YouTube, etc., has become a powerful tool for communication. The majority of online users are currently attached to more than one social network. Individuals usually belong to several social groups simultaneously and share different personal facets with the members of each group. From the personal spaces of Facebook, MySpace, Orkut, and Windows Live to more interactive platforms, such as wikis, blogs, Twitter, and online worlds (e.g., Second Life, World of War-craft), hundreds of millions of users are connecting with each other and building online communities. Furthermore, a more cyber-oriented workforce, accessing SNS from different locations by Social Networking applications on smartphones and other numerous mobile devices, could skew the information path patterns in unexpected ways with undesirable consequences.

Social networks serve two main purposes: to connect with friends, share personal information and meet new people; and to connect professionals, share knowledge, experiences and plan future career steps (Trusov, Bucklin and Pauwels, 2009).

While Facebook and Twitter are mainly focused on the first purpose of SN, with users sharing pictures and personal information (Papacharissi, 2010; Dutta and Fraser, 2009), LinkedIn fosters the second one. Here, individuals long to market their skills, competences and work experience and to connect with professionals in their or similar fields of expertise (Dutta and Fraser, 2009). Individuals upload job qualifications and application information on their LinkedIn profile.

SNS users drive both demand and supply – content creation is as easy as content access; information analysis is as easy as information dissemination. Thus, several drawbacks are associated with the SNS usage.

Traditional offline criminals also use social networks to plan criminal activities or are targeting their activities to online victims, so offline criminal activity is migrating to cyberspace. Cyber-criminals have adapted their strategies and tools to target social-network users and have improved attack technologies.

Unfortunately, a high percentage of social media users allow their information to remain public. Gross and Acquisti (2005) after analyzing 4000 Facebook profiles of Carnegie Mellon University students, found threats emerging from personal information posted in social networking site. Only 1.2 percent of users changed their default privacy preferences. Hence fully identifiable information like (first name, last name, personal image, hometown, date of birth, ZIP code) were easily available to anyone registered on Facebook. These information could be used, for example, to estimate a person's social security number or finding sensitive medical information (Gross, & Acquisti, 2005).

Using the information available on Facebook profile one can easily determine the likely physical location of a person. Similarly, the research done by Bit Defender reveals that 75 percent of individuals use the same password for social networking sites and email (Study reveals 75, 2010).

Today, many Open source intelligence (OSINT) tools for gathering and analyzing data for intelligence purposes could be employed, as well as, a lot of products were developed for professional data mining technology to dig up the potential connection between different groups and individuals on social networks, providing Personal Profile, Personal Relationship Analysis, Personal Mention Analysis, Personal Messages List, Personal Content Analysis, etc. However, countries of poor economic status cannot afford such applications (tools). But despite this fact, as users unintended and uncareful behavior on SNS still remain the weakest element in the chain of events, this study was focused on its security implications and perspectives on potential future development paths, using only data mined freely available on the web.

The motivation for choosing LinkedIn (before their merge with Microsoft) as a starting point in this investigation was the fact that, many employees are still using public facing social networking sites to manage their career. Further, speaking of spear phishing, ‘invitation to connect on LinkedIn’ is consistently listed among the most-used subject lines in phishing scams. In addition to completely fabricated accounts, it’s very common for hackers, scam artists and terrorists to create fake profiles for real life individuals.

With respect to the fact that human factors, alongside with the technical infrastructure, are susceptible to making errors which could compromise aviation safety, pilots and co-pilots were found in the focus of this research, having in mind, that, besides own errors, they can also be exposed as targets for terrorists, who aim to search for, and find them.

Any mistake (accidental or intentional) made by these two bear the potential to be fatal, or even producing the chaos and resulting economic losses, and finally, there also exists an angle of psychological threat, whereby cyber interference may play havoc on the integrity of air transport. Therefore, it is clear, that terrorists analyze publicly available data to gather information on pilots or co-pilots, in order to reach and blackmail them or use other means of force to violate airplane safety. As global political crisis does not know borders or boundaries, samples (companies) originated from different continents.

2. Data available on SNS

The main goal of the study was to collect personal data about pilots and co-pilots, working for two airlines, that are available from business social network "LinkedIn". One European and one airline from the Middle East were selected, for which it is assumed that they, probably, could be in the focus of terrorist groups. The further step was to analyze various kind and amount of sensitive personally identifiable information (PII), freely available on the web, that could be collected and reached without requiring visitors to be registered or logging in.
Information comes from scanning LinkedIn for the key words: "pilot xxx airlines" where xxx represents the name of the company (airline). In order to protect the confidentiality of Airline operators studied, in the further text, they will be designated as "X Airline" and "Y Airline", respectively. The number of employees found is in Table 1.

Table 1
Search Results for the selected airlines (number of employees found)

X Airline	Y Airline
142	1144

From search results for the "X Airline", only 80 people were employed as pilots in selected airline, other 62 from search results were connected to keywords but not relevant for research. Therefore, further analysis was conducted on 80 persons who, actually, are pilots employed by the airline. For the second airline, "Y Airline", 100 persons comprised the representative sample for analysis (Table 2).

Table 2
Publicly available profiles for two samples

	X Airline		Y Airline	
	N°	%	N°	%
Sample size	80		100	
Public profile	42	52,50	50	50,00

2.1. Types of data available on SNS

Persons who wanted to secure their online data have hidden their profile to all visitors except for registered recruit accounts (head hunters). This kind of data was marked as N/A (Table 3).
Still, the following data resulted from the search results could occur – the name of the employee is hidden, but there was a personal photo present and visible to all, or cover photo including a family member (partner or a child). Likewise, if there is a personal photo available, we could determine person's gender. Business data available were person employment history and education.
After gathering this information, advanced search for the same person by its name and surname on dozen most popular social networks was conducted.
Home area data information was collected in order to narrow search results of the extensive amount of data gathered for first and last name combination as key words.
Hobby was indicated if existed or it was mentioned. For comparisons, available additional information on a number of persons and different groups connected to examinees were collected.
For people with profiles on multiple social networks, if the same group was found on different SNS, they were treated as one.
The number of published photographs indicates the total number of all the pictures on one`s profile, regardless what they represent. Photos from travels often include family members so they were interesting from that aspect, and travel tags were interesting for further travel analysis. Family photographs indicate if there were family pictures visible, as well as personal and partners photo. A number of children was relevant to gain full vulnerability of a person. The last information considering possible addresses were relevant only for the X airline (white pages were not available online in case of Y airline).

Table 3
Outcomes of search results (data available)

Data	Possible results
Visible name	Name; N
Sex	M; F; N/A
Age	Age; N/A
Business Data	Employer(s), School(s), N/A
Other Social Network Affiliation	Name of Social Network(s), N, N/A
Home area	Area; N/A
Hobby	Y; N/A
Number of groups following on LinkedIn	Number, N/A
Number of linked persons on LinkedIn	Number
Number of different groups following on other Social Networks	Number; N/A
Number of linked persons on other Social Networks	Number, N/A
Is profile visible on Social Networks	Y; N; N/A
Number of published pictures	Number
Pictures from travels	Y; N; N/A
Travel tags	Y; N; N/A
Family photographs	Y; N; N/A
Personal photo	Y; N; N/A
Partners photo	Y; N; N/A
Number of children	Number; N/A
Number of possible addresses	Number; N/A

3. SNS Security – Data Protection

Websites and applications powered by social networks have many restrictions depending on visitor's status. Individual who wish to review and collect data on social network website (or Android application) has to be registered as a member, make its own profile and then reach available data. For that purpose, one needs nothing more than a valid e-mail address. Free e-mail address is available on numerous web services. All social network members can customize their individual privacy settings (lock visibility to a wide audience), control the kind and amount of information they share (make their own public data selection) and limit access to important information.
The first step of the investigation was to find if the employees of two aviation companies have profiles on a social network "LinkedIn". Search results were available only for a limited time period. After two days period search results (if saved) were available only for visitors who have paid membership.
For all social networks, the unique rule was that all the profile data will be visible only to directly connected the third party. So, one has to send a connection request and get confirmation from the particular user in order to see the full profile information.
Only public data available to all members were selected to collect because that would not compromise the identity of persons who were performed the searching tasks on social networks.
Considering profile data availability, there were no significant differences between selected airlines, in both cases, about 50% of the profiles were available. For further analysis only public profiles were selected.
It has to be emphasized that both of the airlines are multicultural and multinational, so there were no differences (of any type, i.e. religion or else) between samples that would contribute to significant issues regarding analysis or interpretation of the results.

4. Results

Analysis of the structure and components of the two airline employees profiles, show the difference in a number of public profiles available on other social networks, i.e., with no restriction of accessing any kind of contents, with detailed personal information provided and visible on one or more social networks (Figure 1). The staff of X Airline who are LinkedIn members are less cautious, one third of them revealed personal information to the wide public audience, while only 7.69% of Y Airline employees could be identified via online search. Obviously, they are much more concerned with their privacy in comparison to the X Airline employees.

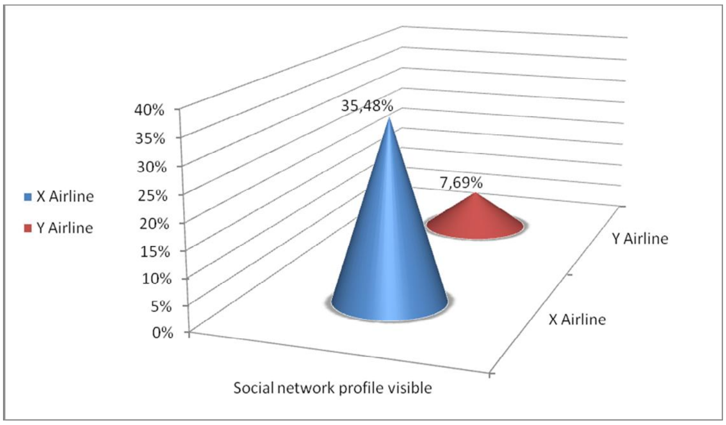

Fig. 1.
Number of Public Profiles Available on Social Networks

The fact that almost all of profiles had visible school and employment history data visible was not surprising. Presence on another SNS was also the subject of analysis. Near 74% of the X Airline employees have profiles on other SNS, besides LinkedIn, as well as 52% of the Y Airline staff. But, the percentage of employees having accounts on more than one SNS is very low, ranging from 4% for Y Airline, to 12 % for X Airline employees (Figure 2). None of the employees has the profile on more than two SNS.

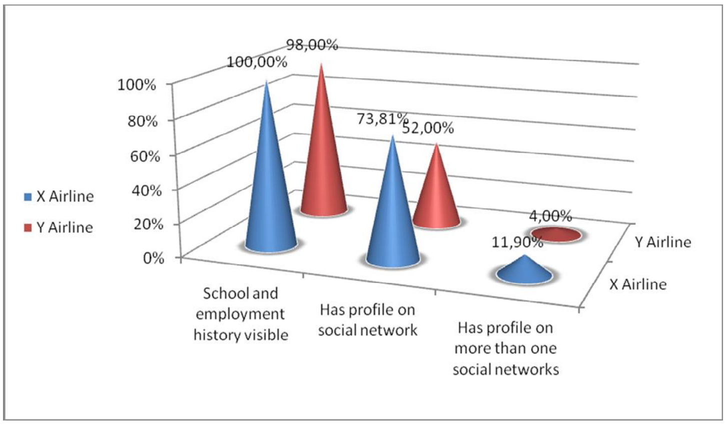

Fig. 2.
Professional history and data about Presence on SNS

Demographic structure of both samples (from the two airlines) were similar. The average age was around 42 years for both samples (42,76 years for the X and 41,54 years for the Y airline). Two airline employees show similarities in some parameters of their online exposure and activities, too. Among them, in a number of groups and followers on LinkedIn, as well as in group membership on other SNS. However, there are some differences in an average number of connections on various SNS and an average number of photos posted on their profiles (Figure 3).

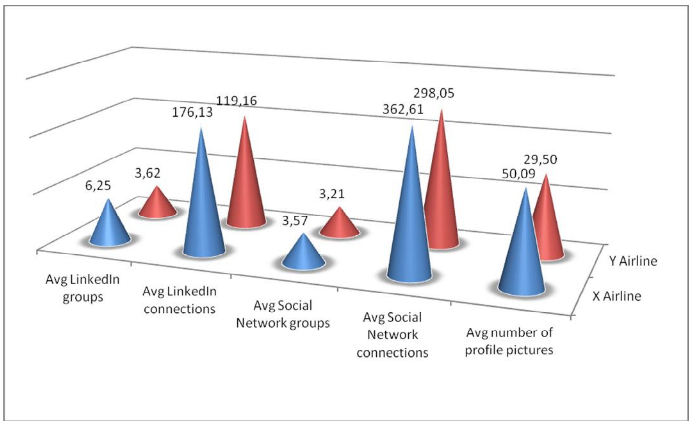

Fig. 3.
Activities on Social Networks

Considering the number of photographs published by members on various social networks, there are differences between the two airlines. Employees from X airline posted more photos, whether personal, their partners (spouse) or photos and data about their children, compared to those from Y airline (Figure 4).

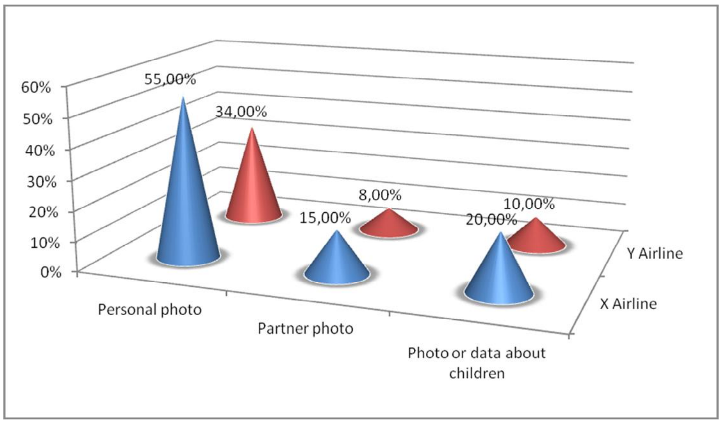

Fig. 4.
Photographs posted on all Social Networks (for two airlines)

On the basis of the results presented, the conclusion could be drawn, that the employees from X airline show higher online exposure in terms of personal information provided and visible on one or more social networks, such as number of profiles on SNS, average number of connections on various SNS and average number of photos posted on their profiles (rather personal or of family members). On the other hand, two airline employees are similar with respect to school and employment history visibility, an average number of groups on other SNS than LinkedIn. Y airline employees are more cautious, much more concerned with their privacy and more selective in the type of information they provide available to a wide audience.

5. Discussion and Conclusion

Personal data security is very important in all aspects of life. Special treatment of personal data is expected for all the employees in air traffic and transport. Groups of employees such as pilots and co-pilots need to be alerted that their personal data should be hidden. With no doubt, users (employees) may compromise personal and systems' security and safety by posting certain types of information on social networking services.
To reduce or eliminate the risk of sensitive or classified information being posted on social networking sites, an organization needs to stipulate in its policies what can and cannot be posted on both internal and external social networks site (Disruptive information technologies, 2010).
As long as individuals, organizations and intelligence analysts are aware of the perils involved in using social networking sites, it will be harder for criminals and terrorists to plan and execute malicious activities and attacks (Social Media: A Valuable Tool With Risks, 2013).
Therefore, pilots and copilots responsible behavior on SN have to become an essential and inevitable part of the cybersecurity of information and communications systems for critical infrastructure technical measures and policies, and in front of all, of an up to date training and educational system in order to establish an well designed ‘human firewall’ of a system.
As could be seen from the results of the study, even simple inspection, via online search, without applying sophisticated OSINT tools and similar products, provide a massive amount of data about airline staff which can be misused making them a potential target for cyber criminals and cyber terrorism.
Thus, an information (cyber) security culture must be established. The information security culture shall consider each human factor carefully to improve user security behavior (Al Hogail, 2015). Al Hogail (2015) discuss the human factor diamond which represents the four domains of human factors that influence information security behavior. The “preparedness” domain is mainly concerned with training and awareness, knowledge acquisition, and change of old practices. The “responsibility” domain is mainly related to employees’ practices and performance such as monitoring and control, reward and deterrence, as well as acceptance of responsibility.
The “management” domain is concerned with security policies, practices, directions, and interaction issues.
Finally, the “society and regulations” domain is mainly related to social and cultural aspects and regulation issues (Al Hogail, 2015).

5. 1. Recommendations

To tackle the problems that may arise from sensitive personally identifiable information being freely available on SNS, it is necessary to identify exploits and vulnerabilities and to make recommending guidelines to various cyber-security threats elimination and prevention.

Measures to protect information and communication technology systems used for civil aviation purposes from interference that may jeopardize the safety of civil aviation must be developed. These measures include, but do not have to be limited to the evaluation, location and prioritizing of cyber-risks, but urge incorporation of unpredictability factors into the system.
The biggest and most important protective measure is user education. Training of personnel at various levels in various capacities to meet the challenges posed by cyber threats is necessary, in order to launch response attacks.
The training should include instruction in using social media in order to feel comfortable using it, as well as how to eliminate personal information from individual social media.
Also, a certification examination for employees which test the employees' cyber-security knowledge.
It is important to point out that there is always the possibility that information posted on the Internet (personal details like date of birth or resume details) can be shared beyond how it was intended.
High priority should be on promoting unceasing awareness, providing leadership through social media education, training, and to diligently manage employees on-line exposure (FBI Law Enforcement Bulletin, 2012).
The Symantec Corporation (Symantec Corporation, 2013) propose seven basic security measures for using social networking sites, regarding sharing passwords to social networking sites; avoiding posting anything that should not be public knowledge like sensitive information such as a phone number, birthdate, or vacation status; ignoring links with "enticing titles" sent by friends; need to verify if posted links (such as on a Facebook wall), are valid; limiting the number of those who can access a profile to family and friends; as well as keeping to be informed of changes to privacy policies of social networking sites (Symantec Norton Report, 2013).
The above-mentioned guidelines are similar to those recommended for Military personnel when posting information using social networking sites (U.S. Army, 2011).
The U.S. Army Social Media Handbook listed "Security Items to Consider":

- "Take a close look at all privacy settings. Set security options to allow visibility to 'friends only'.
- Do not reveal sensitive information about yourself such as schedules and event locations.
- Ask, "What could the wrong person do with this information?" and "Could it compromise the safety of me, my family or my unit?"
- Geotagging is a feature that reveals your location to other people within your network. Consider turning off the GPS function of your smartphone.
- Closely review photos before they go online,
- Make sure they do not give away sensitive information, which could be dangerous if released,
- Make sure to talk to family about operations security and what can and cannot be posted,
- Videos can go viral quickly; make sure they don't give away sensitive information. "

What is well known, but never enough pointed out, is to ensure that password length/complexity/reset/history requirements are defined and configured. Regardless of platform, using secure passwords and encryption on every device that touches the business (phones, tablets, laptops, desktops) is necessary. Moreover, to restrict who can find data via online search and to limit what people can learn about the company through public searching (Ackerman and Schutte, 2015).
Although guidelines listed above referred to the Ministry of Defense and Internet Services Providers, they can be transferred to the Civil Aviation. Hence, the need arises to provide a framework for a risk-based approach to prioritize the protection of high-value information across the system and allocate resources in correlation with the greatest risks, but not of lower importance is to ensure periodic risk assessments. Within this paper only part of the findings is presented, the next steps will include a profound statistical analysis and interpretation of the results.

SESSION 3: INFORMATION COMMUNICATION TECHNOLOGY AND TRANSPORT

ANALYSIS OF VEHICLE TO INFRASTRUCTURE (V2I) COMMUNICATION EFFICIENCY USING THE ZIGBEE PROTOCOL

Răzvan Andrei Gheorghiu[1], Valentin Iordache[2]
[1,2] Transport Faculty, Electronics Dept. "Politehnica" University of Bucharest – Bucharest, Romania

Abstract: Information is nowadays the key element in every aspect of life. It is easier than ever to acquire and transmit large amount of data that is then used in many systems that control different aspects of the world we live in. This is also true for road traffic information, where modern Traffic Management Systems (TMS) collect information about the vehicles, speed, queues' lengths, emissions etc. - which is afterwards included in complex algorithms that determine the best possible signaling times for the traffic lights in road network junctions. But usually the information is obtained in fixed points of the network, meaning the TMS has detailed knowledge of the actual traffic conditions only in these points and can only assume/estimate what is happening between them. Floating car data represents a method to obtain information from the entire road network, but it implies a more complex communication approach, being able to acquire actuated data along the routes. A dense communication network also implies a considerable amount of energy required for its functioning. Modern communication protocols, such as ZigBee, may be such an alternative, presenting many advantages from these points of view, and may represent a solution for vehicle-to-infrastructure (V2I) communications. In this article the possibility of implementing a communication network based on this protocol has been analyzed, testing the possibility of a faster connection between devices, one of the key elements in implementing a V2I communication network.

Keywords: ZigBee, Wi-Fi, interferences, vehicle-to-infrastructure communication, communication handshake time analysis.

1. Introduction

Communications represents the backbone of any modern transport support system: traffic management, public transport management, passenger information, toll collection, law enforcement and so on.
Implementation of new services or features may be based on existing communications or, if this cannot be done, new communication networks have to be installed. In the latter case a detailed analysis must be carried out for the requirements of information transmission that takes into account the existing communications in order to avoid interference with the consequence of failure to proper submit the information. Analysis of interference with existing networks should be carried out from two perspectives: new implemented network is influenced by existing communications or it can influence the networks already installed.
Communication technologies are mainly improved to allow the transmission of increasingly larger quantities of data. But this is not always necessary, in many cases there is some bandwidth left unused. Neither in terms of energy is this solution proper.
This paper examines the possibility of implementing cheap, energy efficient network that will ensure a minimum (essential) information transfer between vehicles and infrastructure (V2I communications). This network has many practical applications, such as:

- Transmission of certain categories of vehicles' position at certain points in the network: e.g. identify public transport vehicles in the intersections' proximity to ensure their priority,
- Data collection on the route, based on sensors installed on-board of vehicles that download information at every intersection (this information is useful, for example, for traffic management systems),
- Transmission of information related to passengers inside vehicle - useful for evaluating the efficiency of public transport,
- Loading the vehicle information system with updated information related to specific events in the next portion of the route.

The proposed solution is to implement ZigBee communications that meet the requirements defined above, for which we will assess the possibility of implementation, and the effectiveness of communication, given that there are other modes of wireless communication already installed. The paper is structured as follows: Chapter 2 presents a general description of the ZigBee communication protocol, detailing aspects to be taken into account in implementing the network. Chapter 3 presents an analysis of wireless communications that can be present in the vehicular environment, emphasizing their technical characteristics. Chapter 4 offers details regarding possibility of implementing ZigBee mixed with other communications methods, and chapter 5 presents the results of connectivity tests that were carried out in laboratory environment.

2. ZigBee protocol

ZigBee is a wireless communication protocol based on IEEE 802.15.4 specification and designed mainly for high energy efficiency, but having a relatively low data rate compared to other modern communications. It is mainly used for the implementation of the Internet of Things concept, by employing a very good resource management and

[1] Corresponding author: andrei.gheorghiu@upb.ro

implementing a very efficient data transfer that consider only the essential information transmission. It has many advantages, such as reliability and robustness, energy efficiency, scalability, security and universality (ZigBee Alliance, 2016).

The main technical features of ZigBee Technology are (ZigBee Alliance, 2007; Hou et al., 2009):

- Radio Frequency/Bands:
    - 2.4 GHz with 16 channels (in fact 2.4-2.4835 GHz; channels no. 11 to 26) for global use, each of them being 2 MHz wide with 3 MHz inter-channel gap-bands. The center frequency of each channel is calculated as f_{ch} = (2400 + 5*k) MHz, where k = 1, 2, ... 16. The throughput is 250 Kbps,
    - 915 MHz with 10 channels (in fact 902-928 MHz; channels no. 1 to 10) for N. America, Australia and a few additional countries; throughput of 40 Kbps,
    - 868 MHz with 1 channel (in fact 868-870 MHz) for EU countries and Japan.
- Network type: self-organizing, self-healing, ad-hoc dynamic mesh,
- Network size: up to 64,000 nodes managed by a single coordinator,
- Network access: CSMA-CA (Carrier Sense Multiple Access with Collision Avoidance),
- Device types:
    - Coordinator:
        - One ZigBee coordinator per network,
        - Root of the network tree,
        - May bridge to other networks,
        - Stores information about the network (like radio-channel, repository for security keys, etc.).
    - Router:
        - Parse data from other devices,
        - Has the role to extend network range,
    - End-device
- Beacon and non-beacon enabled networks:
    - Beacon enabled network, in which the router sends periodic beacons to other nodes to confirm their presence. The coordinator and the clients wake up from sleep at precise intervals to exchange messages, requiring precise timing. This kind of network has lower duty cycle and extended device battery life,
    - Non-beacon enabled network, in which clients transmit whenever an event occurs and the network coordinator keeps its receiver on all the time, needing more power supply,
- Automatic network establishment by the coordinator
- Modulation: Offset quadrature phase-shift keying (OQPSK) and Direct Sequence Spread Spectrum (DSSS),
- Transmission power: 1 mW (typical),
- Packet length: 352 µs - 4256 µs,
- Addressing modes:
    - 16-bit (short),
    - 64-bit IEEE addressing ,
- Data transfer distance: typical 10 to 75 meters, but can easily reach 100 meters within line of sight and lack of other interferences,
- Battery life: up to 1000 days.

3. Wireless communications overview

In the last years, a lot of communication technologies and many types of indoor or outdoor equipment are using the 2.4GHz band. Some of the possible users and interferers are: 802.11b,g,n networks, Bluetooth Pico-Nets, 802.15.4-based Personal Area Network (PAN), Cordless Phones, Home Monitoring Cameras, Microwave ovens, Wireless headsets, Motorola Canopy systems and WiMAX networks (ZigBee Alliance, 2007). A detailed comparison between these interferers can be observed in Table 1.

Table 1
2.4 GHz band interferers

	No. of channels	Lower frequency	Higher frequency	Spacing	Bandwidth
Wi-Fi	13	2412 MHz	2472 MHz	5 MHz	20 MHz
Bluetooth	79	2402 MHz	2480 MHz	1 MHz	1 MHz
802.15.4	16	2405 MHz	2480 MHz	5 MHz	3 MHz
Cordless phones	-	2400 MHz	2500 MHz	5 MHz, 10 MHz	-
Home monitoring cameras	various specifications, mostly same as Wi-Fi				
Microwave oven	-	2450 MHz	-	-	-
Wireless headsets	various specifications				
Motorola Canopy systems	18	2415 MHz	2457,5 MHz	2,5 MHz+	20 MHz
WiMAX	-	2345 MHz	2360 MHz	-	1,25 - 20 MHz
		2500 MHz	2690 MHz		

When talking about using ZigBee as a solution for V2I communications, some of the presented interferers must be considered. 802.11b,g,n networks are usually stationary, so a particular area in which they are present can be seriously affected by the large volume of data that can be transferred using this technology, this being the case for a road junction. Bluetooth Pico-Nets have a limited range, few network devices and usually small data rates, but they should be considered because some of them may be present in moving vehicles or on the road side (headsets, car keys, etc.). Cordless Phones, Home Monitoring Cameras, Wireless headsets and Microwave ovens are usually used indoors and have less influence on road infrastructure equipment; also, some of them have same specification as Wi-Fi. Motorola Canopy systems are rarely used, but when present they should be considered, and WiMAX networks, as seen from Table 1, are using close frequencies but with small chances of interference. As a conclusion, a more detailed comparison between the most likely to interfere communications in 2.4 GHz band is presented in Table 2.

Table 2
Protocol comparison

Protocol	ZigBee	Wi-Fi	Bluetooth
Modulation technique	Direct Sequence Spread Spectrum (DSSS)	Direct Sequence Spread Spectrum (DSSS), Orthogonal Frequency Division Multiplexing (OFDM)	Frequency Hopping Spread Spectrum (FHSS)
Operating frequency bands	2.4 Ghz, 915 MHz and 868 MHz	2.4 Ghz, 5 Ghz	2.4 Ghz
Maximum network speed	250 kbit/s	several Gbits/s	1 Mbit/s
Network range	Up to 75m	10s of meters up to 100m depending on antennas and line-of-sight	1 or up to 100m, depending on radio class
Typical network join time	30 milliseconds	several seconds	3 seconds
Battery	Not rechargeable (one reason batteries will last for up to 10 years)	Intended for frequent recharging	Intended for frequent recharging

As seen from Table 2, ZigBee communication uses DSSS, and this it helps mitigate coexistence issues with Bluetooth devices (NXP Laboratories, 2013). Also, as mention by Sikora & Groza (2005), tests have shown that the influence of Bluetooth over ZigBee consists in a non-critical increased packet error rate. So, the main issue remains coexistence between ZigBee and Wi-Fi, which will be our approach in this paper.

4. ZigBee – Wi-Fi interferences

In Table 3 is presented a list of the ZigBee channels and Wi-Fi conflicts. It results that channels 1, 6, and 11 of Wi-Fi are the ones that should at first be considered when implementing a ZigBee communication structure in the area. As seen in Figure 1, these channels are more likely to be used because the space between them is big enough so that they don't interfere with each other.

Table 3
ZigBee channels (NXP Laboratories, 2013; Digi Wiki, 2014)

ZigBee channel		Lower Frequency	Centre Frequency	Higher Frequency	Wi-Fi Conflict
dec	hex				
11	0x0B	2.404 GHz	2.405 GHz	2.406 GHz	Overlaps Ch 1
12	0x0C	2.409 GHz	2.410 GHz	2.411 GHz	Overlaps Ch 1
13	0x0D	2.414 GHz	2.415 GHz	2.416 GHz	Overlaps Ch 1
14	0x0E	2.419 GHz	2.420 GHz	2.421 GHz	Overlaps Ch 1
15	0x0F	2.424 GHz	2.425 GHz	2.426 GHz	Overlaps Ch 6
16	0x10	2.429 GHz	2.430 GHz	2.431 GHz	Overlaps Ch 6
17	0x11	2.434 GHz	2.435 GHz	2.436 GHz	Overlaps Ch 6
18	0x12	2.439 GHz	2.440 GHz	2.441 GHz	Overlaps Ch 6
19	0x13	2.444 GHz	2.445 GHz	2.446 GHz	Overlaps Ch 6
20	0x14	2.449 GHz	2.450 GHz	2.451 GHz	Overlaps Ch 11
21	0x15	2.454 GHz	2.455 GHz	2.456 GHz	Overlaps Ch 11
22	0x16	2.459 GHz	2.460 GHz	2.461 GHz	Overlaps Ch 11
23	0x17	2.464 GHz	2.465 GHz	2.466 GHz	Overlaps Ch 11
24	0x18	2.469 GHz	2.470 GHz	2.471 GHz	Overlaps Ch 11
25	0x19	2.474 GHz	2.475 GHz	2.476 GHz	No Conflict
26	0x1A	2.479 GHz	2.480 GHz	2.481 GHz	No Conflict

These conflicts are also represented in Figure 1.

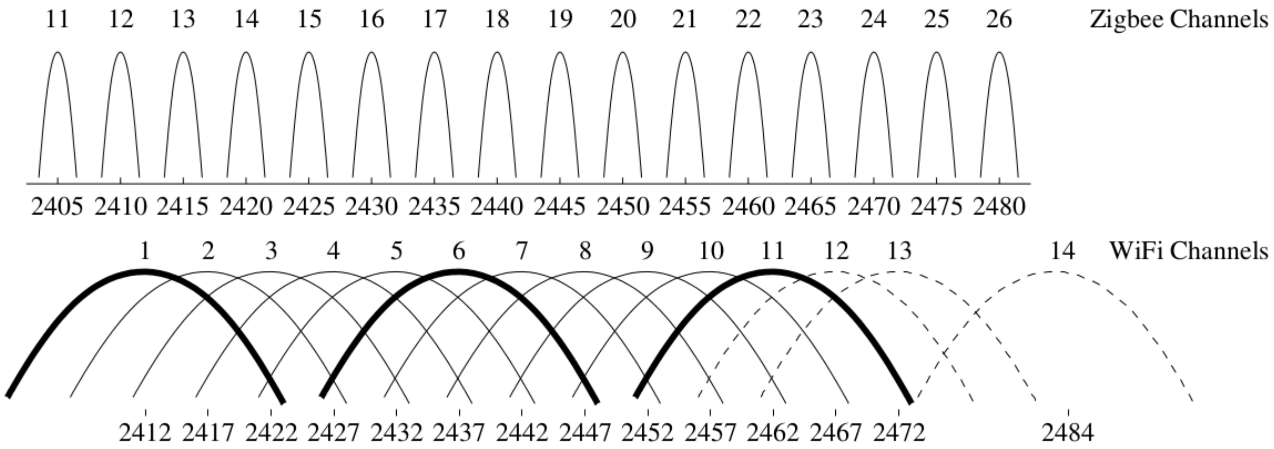

Fig. 1.
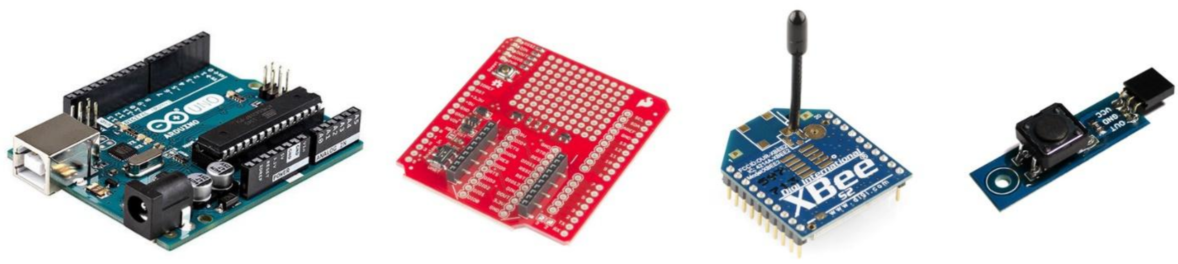
ZigBee and Wi-Fi Channels (Liang et al., 2010)

There are many articles and studies that have analyzed the possibility of implementing ZigBee communications in the places where Wi-Fi or other 2.4 GHz wireless communications are already implemented. All of the literature studies revealed the same conclusion regarding ZigBee interferences: the most significant interference is the one produces by Wi-Fi.
Zhao et al. (2014) presented a mixed ZigBee / Wi-Fi communication network that was installed in order to verify the influence of each communication protocol on the other. The tests have been performed both in symmetric (802.11n and 802.15.4 nodes are able to hear each other) and asymmetric (802.11n senders cannot detect 802.15.4 signals) scenarios. The results were that in symmetrical scenario 802.11 networks must work at 40 MHz, but in asymmetrical scenario ZigBee simply cannot be implemented.
Mardini et al. (2012) quantified these findings, testing the effect of increasing ZigBee/Wi-Fi nodes in mixed ZigBee / Wi-Fi communications. The tests have shown a drop in delivery ratio both for ZigBee and Wi-Fi no matter for what network the number of nodes have been increased.
Mangir et al. (2011) have made experiments in noisy and noise-free environment and concluded that the channels 21-24 have packet error rates (PER) of 20-100, while for channels 16, 25 and 26 the determined PER was 0.
Other studies (Crossbow, 2016) have concluded that the percent of received ZigBee packets is, depending on the test performed, between 95.05 and 100%.
Other authors, based on knowledge of ZigBee/Wi-Fi interferences, have tested some solutions to deploy ZigBee without affecting, or being affected by existing Wi-Fi communications: Hou et al. (2009) proposed and tested a method to minimize interferences for ZigBee medical sensors. Huang et al. (2010) have analyzed the possibility of using Wi-Fi white space to deploy a functional ZigBee network.
More radical solutions were proposed by Xu et al. (2011) – to implement multi-channel ZigBee networks that will avoid Wi-Fi interferences, or Youy et al. (2015) to implement a “wise” ZigBee protocol, named WizBee – which solve issues for ZigBee, but not for Wi-Fi.
There were also studies that analyzed the influence of ZigBee communications to Wi-Fi, such as Radunovic et al. (2012), Gummadi et al. (2007), Angrisani et al. (2008), and Wang et al. (2011).

5. ZigBee communication tests

An analysis of communication duration was performed in the laboratory, using the following hardware: one router, two XBee S2 modules, both connected to an Arduino Uno board with an XBee Shield, and one button (Figure 2).



Arduino Uno XBee Shield XBee module Button

Fig. 2.
Hardware components

An XBee 2mW Wire Antenna - Series 2 was used for these tests. The main technical characteristics of this module are: 3.3V @ 40mA needed power supply, 250kbps Max data rate, 2mW output (+3dBm), 120m range, which are good enough for the tests that follows.

One of the XBee modules was set as Coordinator – XB_C and the other was set as End Device – XB_E. XB_E was put into sleep, using Pin Hibernate mode, which means that a digital signal transition from HIGH to LOW on pin 9 of the module (DTR) would wake it up. Both of them were configured to communicate to each other using the parameters presented in Table 4. Parameters not specified in Table 4 will have the default values.

Table 4
XBee Coordinator and End Device configuration

Modified parameters	Coordinator setting	End Device setting
PAN ID	11	11
DH	13A200	13A200
DL	40E779D1	40E922BB
BD	57600	57600
SM		Pin Hibernate

PAN ID (Personal Area Network ID) identifies the network that the device will join. This parameter was changed to avoid joining other possible existing networks.

DH represents the upper 32 bits and DL is the lower 32 bits of the 64 bit destination extended address. Each device was configured with DH and DL of the other device, so they will communicate with each other.

BD represents the Baud Rate, and it was chosen a value sufficient for transmitting necessary data.

SM defines whether the device will have the option to sleep or not. The End Device was set to enter in sleep mode, and to exit it by using a command pin.

The electrical circuit is presented in Figure 3. Pressing the button will determine a LOW to HIGH transition on both pins number 10 of the Arduinos and will have two immediate results: XB_C will start transmitting data and XB_E will be awakened by taking pin 9 (DTR) in a LOW state. The two Arduino boards are connected with a communication cable, necessary to transmit the activation signal from the button and also to keep a distance between modules (in this case was 5 meters). The two resistors are used to establish a known logical level when no triggering signal is available, R1 being a pull-up resistor, and R2 a pull-down one. In order to complete the electrical circuit, the grounds of the two Arduino Uno boards have to be connected.

The tests will focus on determining the time needed for a module to connect to the network and to start receiving data, simulating a connection between an End Device located on-board of a vehicle that enters in the range of a Coordinator, located at the infrastructure level.

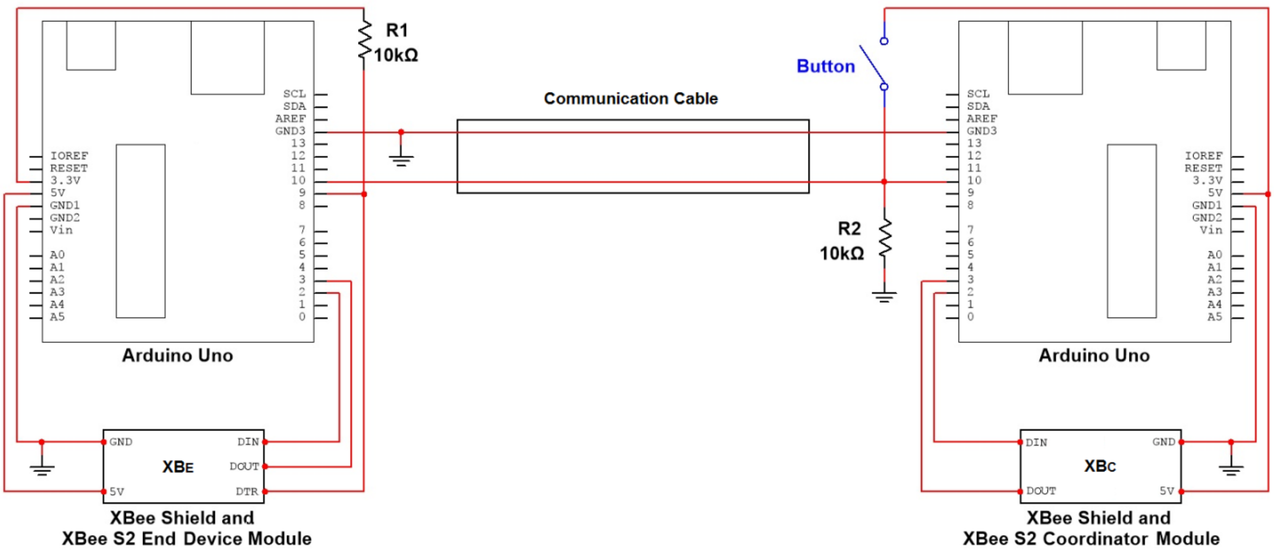


Fig. 3.
Electrical circuit

The testing procedure implied two scenarios:

1. With random Wi-Fi interference (considering that when installing a ZigBee communication network near a road junction it is not possible to know very precise what communications will occur during the network functioning period and, in addition, in the intersections many other signals meet and interfere with each other), and

2. With a router set on the Wi-Fi channel closest to the ZigBee channel that was tested (according to Figure 1) and wireless communication in place (a large file transfer was in progress during this phase of the tests). Hence, the tests have been made for:
    a. ZigBee channel 12 (0x0C), with random Wi-Fi communications and with Wi-Fi communications set on channel 1.
    b. ZigBee channel 17 (0x11), with random Wi-Fi communications and with Wi-Fi communications set on channel 6.
    c. ZigBee channel 22 (0x16), with random Wi-Fi communications and with Wi-Fi communications set on channel 11.
    d. As from other tests (NXP Laboratories, 2013; Digi Wiki, 2014) resulted that ZigBee channels 25 (0x19) and 26 (0x1A) are the ones having less conflicts with Wi-Fi, we have tested these ones with random Wi-Fi communications and with Wi-Fi communications set on channel 13 (the closest Wi-Fi frequency available), but also with Wi-Fi channels 1, 6, and 11 (as being the most frequent channels used).

On transmission start (when pressing the button) XB_C will generate the result of *millis()* function, that returns the number of milliseconds that have passed since the program started running. This value was continuously sent to XB_E. XB_C was set to display the first *millis()* generated at the button press moment and XB_E displayed all the data received and only the first one was considered for comparison. The difference between the two values was calculated:

$$\Delta t = t_{XB_C} - t_{XB_E} \qquad (1)$$

Where; t_{XB_C}: the time indicated by XB_C and t_{XB_C} : the first time indicated by XB_E. The difference between the two values represent XB_E wake up time and connection time (handshake).

$$\Delta t = t_w + t_h \qquad (2)$$

Where; t_w: represents the wake-up time and t_h : the handshake time.
In order to determine the handshake time (the parameters that is of use to us), we have subtracted the wake up time from Δt. t_w is presented in XBee module datasheet (Digi International Inc, 2009), and, for this kind of sleep mode is 13.2 ms. Therefore:

$$t_h = \Delta t - 13.2ms \qquad (3)$$

Additional tests were performed to evaluate the duration of instructions' execution (*millis()* read, variable allocation, data transfer to Arduino Serial Monitor). From these tests it resulted that the total execution time for the programs that have been used is 8 µs, which is negligible.
10 tests have been made for each of the two scenarios. The results of the tests are shown in Figures 4 to 8.

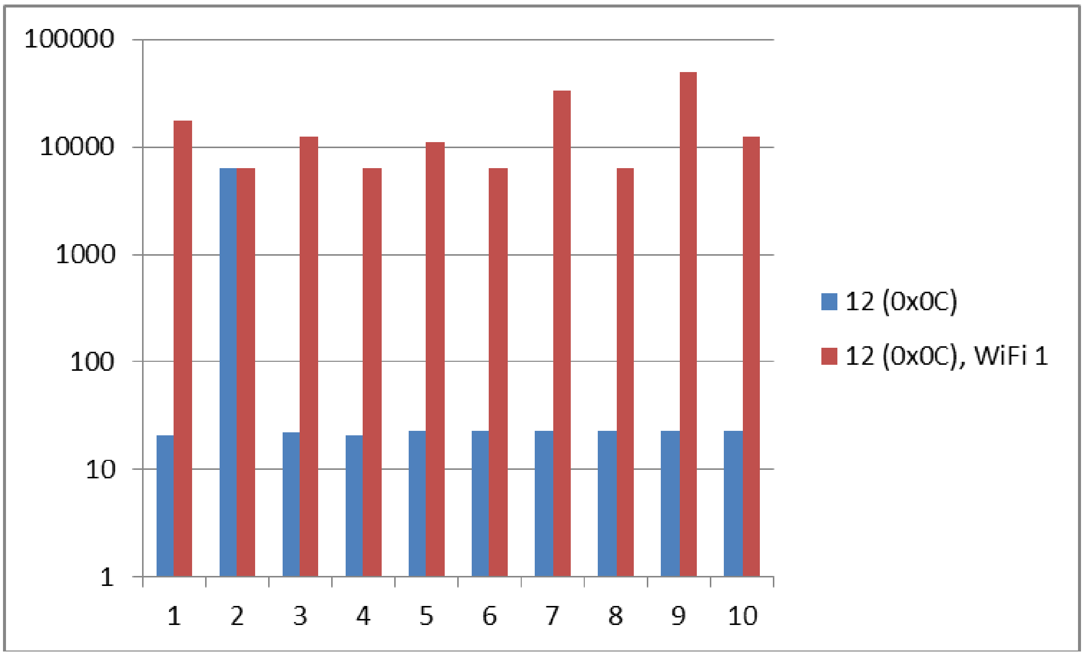

Fig. 4.
ZigBee channel 12 tested in normal conditions and with Wi-Fi communication on channel 1

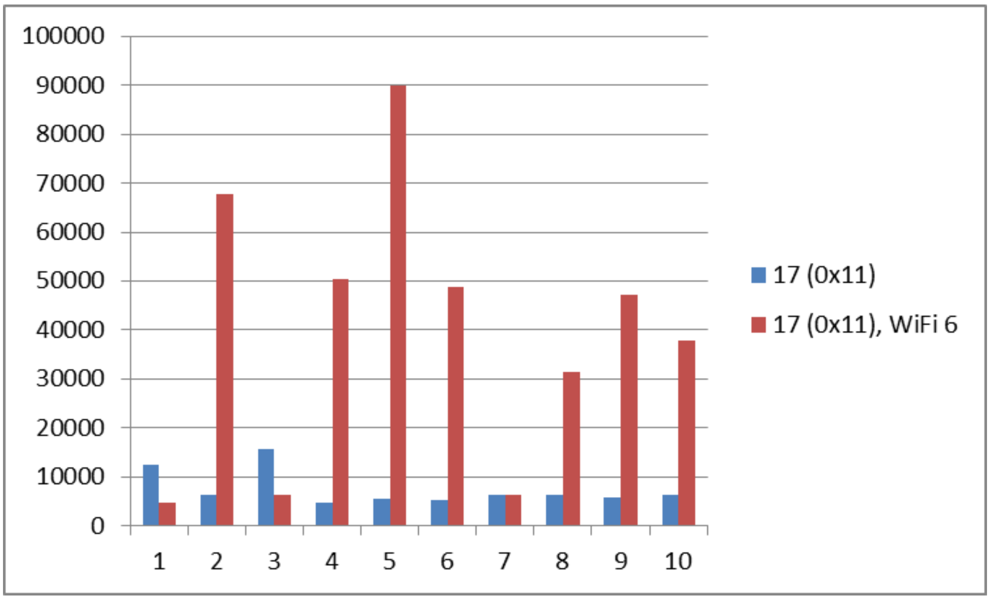

Fig. 5.
ZigBee channel 17 tested in normal conditions and with Wi-Fi communication on channel 6

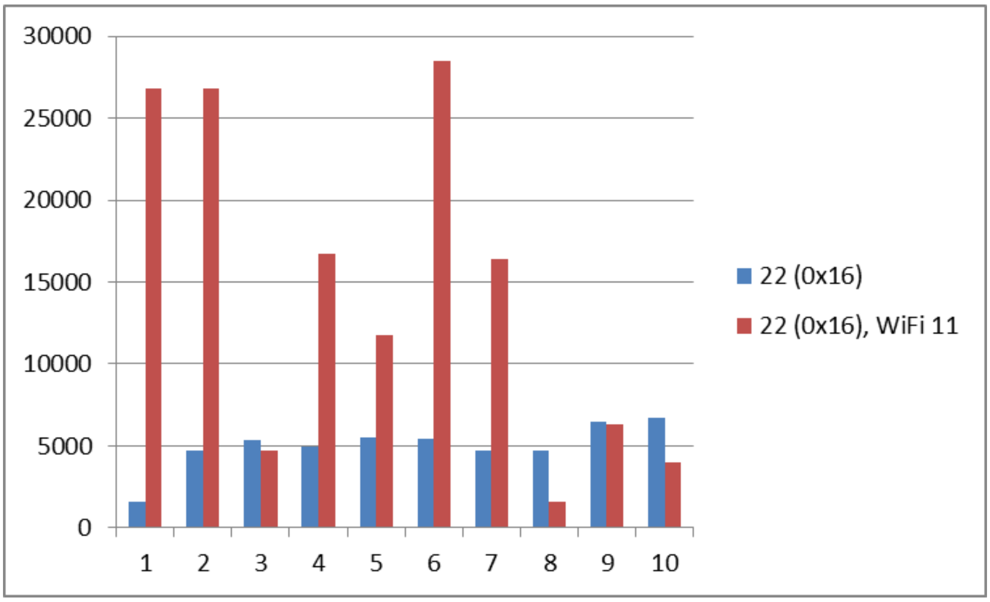

Fig. 6.
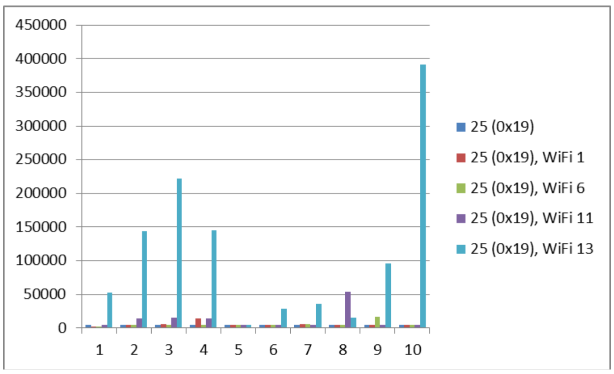
ZigBee channel 22 tested in normal conditions and with Wi-Fi communication on channel 11



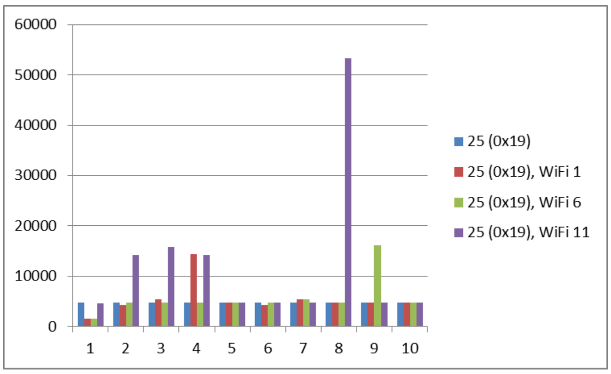


Fig. 7.
a) ZigBee channel 25 tested in normal conditions and with Wi-Fi communications on channel 1, 6, 11, and 13
b) ZigBee channel 25 tested in normal conditions and with Wi-Fi communications on channel 1, 6, 11 for better comparison

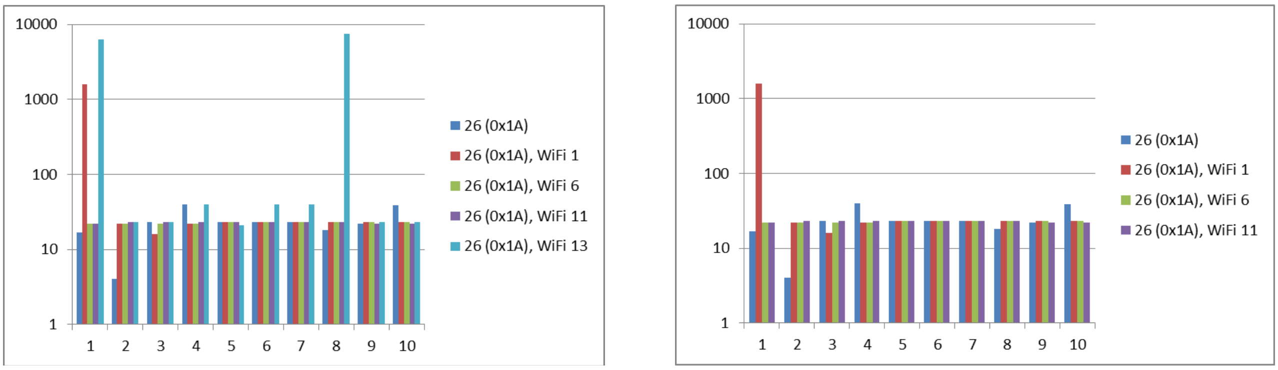

Fig. 8.
a) ZigBee channel 26 tested in normal conditions and with Wi-Fi communications on channel 1, 6, 11, and 13
b) ZigBee channel 26 tested in normal conditions and with Wi-Fi communications on channel 1, 6, 11 for better comparison

From the previous charts we can conclude that there are some values that don't reflect the average situation in a particular scenario. For example, in the last chart there is a spike detected for ZigBee channel 26 when Wi-Fi channel 1 was used to transfer data, but there is only one such case. There is why we have considered that the best method to determine the average situation in the communication would be to calculate the median value of each set. The results are presented in Table 5 below.

Table 5
Median values obtained in tests (milliseconds)

ZigBee channel	Normal conditions	Wi-Fi channel 1 active	Wi-Fi channel 6 active	Wi-Fi channel 11 active	Wi-Fi channel 13 active
12	23	11805.5	-	-	-
17	6293.5	-	42529	-	-
22	5115	-	-	14062.5	-
25	4720	4721.5	4725	4724.5	74082.5
26	23	23	23	23	31.5

6. Conclusion

From the values presented in Table 5 we may conclude the following:

1. ZigBee channels that overlap Wi-Fi channels are heavily affected by Wi-Fi communications,
2. Although channel 12 presents immunity to other random communications, it is disturbed by communications on Wi-Fi channel 1,
3. Channels 17, 22, and 25 present a big handshake latency of more than 4.5 seconds. However, channel 25 presents the same latency in the next 3 tests, proving immunity to Wi-Fi communications on channels 1, 6, and 11. It is only influenced by communications on Wi-Fi channel 13, which has the closest operating frequency,
4. ZigBee channel 26 seems to be the proper solution for implementing ZigBee communications, as it is immune to Wi-Fi communications on channels 1, 6, and 11 and shown only a minor influence by communications on Wi-Fi channel 13.

For the implementation of a ZigBee communication network it is essential to know interferences that may occur. By selecting the proper ZigBee channels and communication parameters, it is possible to implement a new communication network that will ensure a reliable connection, even if some interferences are present. ZigBee is not be the best option if data transfer rate is an issue, other technologies being able to provide much faster data rates. But ZigBee may be a solution for large, new implemented networks (such as access points spread around a whole city or sensor networks), as it is cheap, allows the simultaneous connection of a large number of End Devices to one Coordinator and (also important for large networks) is very effective in terms of energy consumption for all the devices that are connected.
Intelligent Transport Systems are usually based on a large number of sensors acquiring information from different points of the road network, gathering different types of data regarding all the aspects that may be relevant (such as vehicle speeds, traffic density, environmental information, etc.), and transmitting them to the decision factors (like Traffic Management Centers or Traffic and Traveler Information Systems). These sensors may be placed in fixed points, obtaining information only from specific areas, or may be mobile (e.g. placed on public transport vehicles) that are able to gather data from the whole road network, hence providing Traffic Management Centers with a better view of the whole transport system. This communication between mobile devices and road side units usually requires fast connection time (so that a moving vehicle would be able to establish the connection and send the data), low data transfer rates (there are mostly numeric values), and reliability. That is why, we may conclude that ZigBee, if the

network is properly configured, according to the tests performed, may be a proper solution for vehicle to infrastructure communications.

REQUIREMENTS FOR A PRO-ACTIVE COOPERATIVE CRUISE CONTROL STRATEGY EMPLOYING VEHICULAR AD-HOC NETWORKING

Marius Minea[1]
[1] *University Politehnica of Bucharest, Transports Faculty, Bucharest, Romania*

Abstract: The paper makes an analysis on the requirements for a pro-active and cooperative cruise control strategy, based on vehicular ad-hoc networking (VANET) and designed for highway traffic safety management. The algorithm is used to dynamically provide cruising information to vehicles, grouped in a self-organizing cluster. A fast responsive component alerts vehicles if an abnormal traffic event is detected. Each vehicle running the algorithm should be aware and adaptive to the local traffic and communication conditions. Priority is given to alert messages with the role to warn vehicles' drivers of a possible collision, in case of a hard braking of a vehicle, or in case a vehicle rapidly changes heading (yaw). Recommended vehicle-to-vehicle (V2V) communication protocols are also investigated, and a solution based on a self-adaptive clustering algorithm is proposed. The average vehicle headroom, speed and acceleration patterns are analyzed for the local vehicle cluster and a weighted control function (WCF) is built by the algorithm. Taking into account the dynamic environment, appropriate cruise values (velocity and headroom) are used to inform the driver. According to different priority degrees, messages are delivered with the lowest delay possible to all vehicles in the area of interest. The clustering algorithm also takes into consideration an optimal modality to group vehicles in a cluster according to their relevance to the message. Finally, an analysis of the quality of service is performed taking into account parameters such as traffic density and unreliable radio coverage.

Keywords: pro-active cruise control, adaptive clustering algorithm, delay tolerance, weighted control function.

1. Introduction

Road traffic is nowadays in a continuous expansion and essential for any developing society. However, vehicular traffic is frequently subject to accidents, mainly due to the large presence of vehicles and heterogeneous types of drivers, flowing on under-dimensioned and insufficiently adapted road infrastructures. Intelligent transport systems (ITS) are applications aimed at improving traffic safety by delivering appropriate in-time information to traffic participants. One of such applications is the cooperative cruise control with vehicle-to-vehicle communications without infrastructure support, such as Dedicated Short-Range Communications (DSRC). Related applications in the ITS infrastructure that deal with traffic management usually require deployed static sensors in order to acquire traffic and environmental information. Collision warning systems are built for highways, where the speed of vehicles is high and a potential collision may lead to serious injuries or even fatalities. Therefore, the development of cooperative cruising control solutions is highly imperative. The installation, maintenance and exploitation of numerous sensors in a highway infrastructure is, however, expensive and energy-consuming. Recent applications of DSRC came with more advantageous solutions, such as the employment of vehicles as "traffic moving sensors" (or "floating cars"). Collecting and managing data, algorithms and quality of service (latency, throughput, jitter) is, however, not an easy task, because cooperative collision warning systems (CCWS) are mostly non-delay tolerant to safety messages.

2. Literature Review

This section presents state-of-art in the field of cooperative cruising/warning solutions employing VANET algorithms, based on a literature study.

2.1. Cooperative Collision Avoidance - Dynamic Information Processing

The detection of a traffic incident is usually a simple task for the actual advanced traffic information and management systems. Parameters such as: speed, flowing and/or density are usually taken from sensors processing each lane of the highway. Secondary parameters, like vehicle lengths, weights etc. may be used for vehicle classification or other functionalities. If an improper behavior is detected, the system may trigger a traffic event alert. Specific algorithms are employed to correctly distinguish between normal and abnormal traffic behaviors. Some authors (Lee J. and Park B, 2012) assume a connected vehicles environment to create a cooperative vehicle intersection control for improved traffic management. Recent advances in traffic safety employ cooperative driving based on DSRC - such a solution is presented by Amoozadeh, M. et al., 2015. The platooning of large trucks helps in building a common safety approach in driving the vehicles, by maintaining appropriate headroom between each vehicle in the cluster. An interesting approach for traffic safety is suggested by Van der Horst and Hogema, 2013, where time-to-collision (TTC) is defined as a measurement parameter for discriminating normal from critical traffic behavior and sending collision warnings. The authors specify that an important issue in developing collision avoidance systems would be to define a proper warning strategy, acting *only when the driver is really at danger* and immediate action is required. Errors should be avoided, as too many false alarms may easily cause the system to become a nuisance to drivers. Yang et al. (Yang, 2004) consider

[1] Corresponding author: marius.minea@upb.ro

an "abnormal vehicle" such a vehicle that is subject to a mechanical failure, or brakes hardly due to unexpected road hazard and decides to broadcast a warning message to its neighboring vehicles. However, the neighboring vehicles do change very rapidly positions in a real traffic scenario, and to deliver reliably warning messages over unreliable radio networks needs repeated transmissions. Chen (Chen et al., 2010) showed that vehicle mobility patterns caused by varying traffic dynamics and driving behavior may lead to considerable complexity in the efficiency and reliability of vehicular communication networks.

2.2. Radio Connectivity and Quality of Service in VANET

DSRC employs channel bands in the 5.9 GHz band dedicated for safety and non-safety applications. The draft version of the DSRC lower medium access control (MAC) and physical layer (PHY) was published as part of the IEEE 802.11p amendment standard in 2010 for wireless access in vehicular environment. Cassidy (Cassidy, 2013) investigates a cross-layered design for improved vehicular safety messaging. One known problem of dense vehicular environments is message collision that occurs when too many vehicles attempt to simultaneously broadcast. The broadcasting frequency, which depends on traffic density and number of repetitions, corroborated with vehicle mobility, can strongly affect the quality of service and reduce the probability of successful message reception. The message delay for safety applications is also important, and the IEEE 802.11p specification has set a minimum allowable latency of 100 ms for periodic message broadcasts (Chen, 2010). Ghafoor (Ghafoor and Mohamed, 2013) investigates and evaluates the most known protocols for VANET in dense vehicular environments, recommending VADD (Vehicle-Assisted Data Delivery) and SRR (Stability and Reliability Routing) protocols. Nagaraj et al. emphasize that in urban areas, a very bandwidth efficient protocol is Edge-Aware Epidemic Protocol (EAEP) as it reduces the control packet overhead by eliminating exchange of additional "hello" packets for message transfer between different clusters of vehicles. Urban areas are not favorable to radio communications. High density of structures is obstructing direct propagation, or reducing the range of radio signals. The environment is also flooded with signals from dense and various local access points. In this regard, distinctive VANET networking properties are analyzed in (Rievaj et al., 2013), where Rievaj described the main design decisions in building algorithms for these networks. An adapted design of network challenges is presented in figure 1 below.

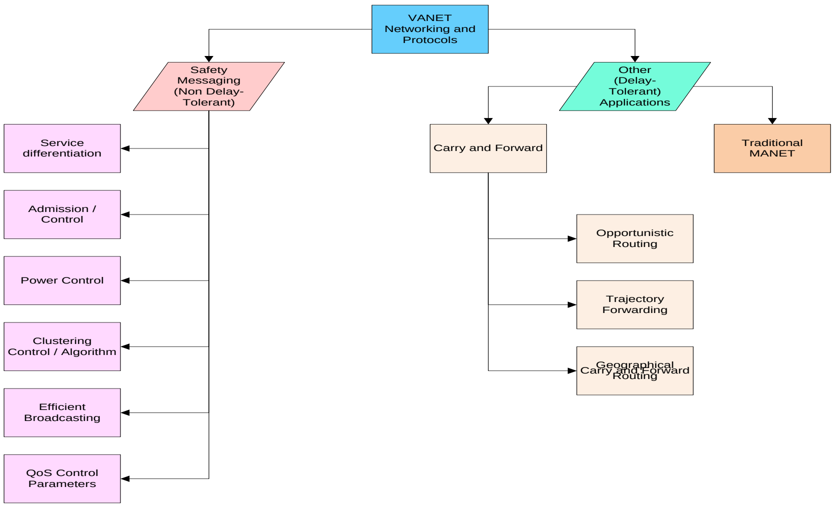

Fig. 1.
Risk factors in assessing VANET performances in a QoS analysis

When selecting a specific protocol for a CCWS application, the following features are important: service differentiation (messages priorities), rules for nodes clustering, power control for limiting cluster boundaries, rules for application-specific clustering to obtain efficient warning messages broadcasting (with reduced collisions and bandwidth consumption) and a firm control of service quality. Yousefi presented elements that should be taken into account for CCWS applications:

- Frequent fragmentation of network,
- Small effective diameter of the network and rapid changes in links' connectivity, causing frequent path disconnections,
- In dense urban areas, the lack of power constraints, leading to interferences with nodes out of interest,
- Widely variable network density - in direct correlation with vehicular density
- Driver behavior affecting of network's topology, and his/hers reaction to received messages. A positive aspect is when the driver behavior can be alleviated to improve traffic safety (by selecting adequate content and moments to deliver messages), while the negative aspect is when critical safety messages arrive in improper moments and may lead to traffic turbulences.

3. Main Factors for a Safe Driving Control Function

In order to make vehicles aware of the traffic environment, the following elements are essential in the design of a system employing dynamic information:

- Velocity and acceleration of cars,
- Average headroom in the lane (in relationship with vehicle density, relative speed and relative acceleration),
- Rate of turning.

In the following, a brief analysis on these factors is undertaken and the components to build a control function are deducted.

3.1. Influence of Vehicles' Velocity and Acceleration

Vehicle's velocity has a major influence on the braking distance. The control function in CCWS should provide a dynamical estimation of the minimum braking distance. Assuming driver's reaction time to external stimuli is ignored, other factors may influence the braking distance: the mass and technical condition of the vehicle, the quality of road surface, weather condition, tires inflation, rolling surface profiling, presence and efficiency of the Anti-lock Braking System (ABS) etc.. Let us denote these as *random conditions*. Defining a mathematical model for the majority of these elements is difficult, or even impossible. Additional coefficients with a certain degree of randomness should be used instead. A commonly agreed contribution of speed at the braking distance until complete stop is described by the following formula:

$$d_F = d_r + \xi_c \cdot d_s \tag{1}$$

Where; d_F : distance to full stop from the observation of the event, d_r : distance traveled by the vehicle during driver's time to react, ξ_c : a random factor that takes into consideration conditions afore mentioned, d_s : skid distance. The skid distance may be, in these conditions, considered in direct interdependence with the vehicle's velocity :

$$d_s = v_s \cdot t_s \tag{2}$$

Where; v_s : initial vehicle speed at the moment of braking, t_s : time until full stop.
Some U.S. regulations assume that an appropriate methodology for determining the initial speed when the braking mark is measurable is to consider an initial test speed for which the effective skidding distance is measured, and then employ the formula:

$$v_m = v_t \cdot \sqrt{\frac{d_s}{d_{st}}} \tag{3}$$

Where; v_m : minimum initial speed, v_t : a previously measured speed for which the d_{st} distance to full stop is known. Replacing these values in (1) gives:

$$d_F = d_r + \xi_c \cdot d_{st} \frac{v_m^2}{v_t^2} \tag{4}$$

This assumes that an initial table with d_{st} and v_t measured and corrected values is available. Considering in more details the elements that contribute to the braking distance, Rievaj et al. in [9] suggested another relationship:

$$d_F^a = (t_r + t_o) \cdot v + v \cdot t_N - \frac{a_N \cdot t_N^2}{2} + \frac{v_N^2}{2a} \tag{5}$$

Where; d_F^a : distance to full stop, considering the variable deceleration during braking, t_r : driver response time, t_o : delay time to effective braking, due to the brakes, t_N : increased time for braking due to vehicles equipped with hydraulic brakes, v : initial velocity of vehicle, v_N : reduced value of speed due to braking deceleration, a_N : braking deceleration of the vehicle during braking increasing, a : full average braking deceleration.
Due to the fact that $d_r = (t_r + t_o) \cdot v$, the formula (5) becomes:

$$d_F^a = (t_r + t_o) \cdot v + v \cdot t_N - \frac{a_N \cdot t_N^2}{2} + \frac{v_N^2}{2a} \tag{6}$$

and considering the random factor ξ_c, a more usable relationship will be:

$$d_F^a \cong d_r + \xi_c [v \cdot t_N - \frac{a_N \cdot t_N^2}{2} + \frac{v_N^2}{2a}] \tag{7}$$

The variable acceleration is measurable with onboard sensors. Therefore, the algorithm should take into consideration equation (4) if such these are not present onboard, or equation (7) if acceleration values are available to system.
If the vehicle is also equipped with an inclination sensor, then a coefficient to correct safety braking distance according to road gradient (in percent) is given by:

$$\delta_g = d_F^a(-\frac{g}{a+g}) \tag{8}$$

Where; δ_g : grade correction coefficient in braking distance, g : the grade coefficient in percent, with $g > 0$ meaning upgrade and $g < 0$ downgrade.

3.2. Influence of Traffic Density and Road Curvature

Regarding the distance that separates vehicles, also known as headroom, it is important to consider that increasing speed of vehicles needs increased headroom, in order to keep a minimum safety distance for collision avoidance. Therefore, traffic density contributes in the calculation of the weighted control function for collision warning. The safety distance between platooning vehicles is also known as *Assured Clear Distance Ahead*, or ACDA, which is mandatory, but sometimes not enough in evaluating the basic speed law[2]. As the solution proposed here does not take into consideration organic observations of the driver, like direct seeing of the event, but instead triggers a warning when the control function components overcome certain thresholds (all values provided only by equipment sensing), the ACDA may be determined in a simpler mode, as function of the appropriate time gap and the operating speed:

$$d_{ACDA} = t_h \cdot v \tag{9}$$

Where; d_{ACDA} represents ACDA when time t_h necessary to the following vehicle to reach the leading vehicle at measured speed v may be computed. Of course, as in the case of equation (4), some unknown variables still remain, such as relative speed and acceleration patterns between the following vehicles. Below a certain distance between vehicles, the movement pattern becomes dependant on the leading vehicle, that is all vehicles that fall under this condition become part of a platoon, behaving in interdependency. Therefore, vehicle platooning should be taken into consideration, when computing the ACDA. This might be derived from the distance to neighboring nodes. For determining the traffic density, the road section may be divided in homogenous cells, of length l_c, indexed by i, an integer that increases in the direction traffic is traveling. Traffic is sampled at each τ time units. Let then $N_v(t)$ be the number of vehicles lying in cell i in the interval $(t, t+\tau)$. We assume the cell length is similar with the radio propagation radius. That is roughly few hundred meters, as in terms of transmitted power, four classes of devices have been defined, whose maximum power ranges from 0 dBm to 28.8 dBm. In the time-space areas where the traffic density is stable, the density $\delta_i(t)$ of vehicles in cell i of length l_c is:

$$\delta_i(t) = \frac{n_v(\tau)}{l_c} \tag{10}$$

Where; $n_{vi}(\tau)$ is the number of vehicles in cell i. The length of the cluster l_c is determined by computing the distance to the most distant neighboring nodes within the communication range. The density component of the weighted control function D_f is then:

$$D_f = \frac{\sum_{l=1}^{n_l} \sum_{v=1}^{n_v} \{v_{l,v}(z) \in C\}}{\sum_{l=1}^{n_l} l_l} \tag{11}$$

with: $v_{l,v}(z) \in C$: vehicles detected in the range of the local cluster C, (onboard computing), l_l : length of lanes in the cluster $(l_l = l_c)$, n_l the number of lanes and n_v the number of vehicles.
In determining headroom, Private Car Units (PCU) may be employed, instead of real vehicle lengths. The average headroom in the cluster becomes:

$$d_F^p = l_c - \xi_3 n_{PCU} l_{PCU} = l_c - \xi_3 l_c \delta_i(t) l_{PCU} = l_c(1 - \xi_3 \delta_i(t) l_{PCU}) \tag{12}$$

Where; d_F^p : average computed headroom, ξ_3 : correction factor describing the real vehicle traffic composition (i.e. percent of small cars in the traffic), n_{PCU} : equivalent number of PCUs in the cell of length l_c, l_{PCU} length of a PCU. Relative acceleration and speed may be considered only if onboard equipment is able to determine by measurement these values. For the speed limitation due to road curvature a common relationship is:

[2] Usually determined in U.S. regulations for road safety

$$v_{RC} \approx \sqrt{\frac{gr(\mu + e)}{1 - \mu e}} \tag{13}$$

with: v_{RC} : the safety limiting speed due to road curvature, g : gravitational acceleration, r : radius of the road curvature, μ : friction coefficient. This must be taken into consideration by the algorithm determining the safety limit speed when the road cell is situated in a curvature.

4. Defining the Clustering Strategy and the Weighted Control Function

The vehicle clustering strategy should be dynamic, taking into consideration the following factors: *communication distance*: the cell dimension (area where clustered vehicles are included) should be kept reasonable small, in order to maintain a clear radio coverage and reduce the interferences, while still enough large to encompass the platooning vehicles that are to be alarmed in case of emergency; rules for including neighboring vehicles (nodes) in the cluster:

- *only vehicles traveling in the same direction;*
- *only vehicles behind the alert message originator;*
- *group and maintain in the cluster only neighboring vehicles that have a relative speed within a certain threshold (eliminate from the cluster those vehicles that travel much faster or slower than the considered sourcing vehicle);*
- *vehicles traveling on other lanes, but in same direction; vehicles traveling in reverse direction are not to be considered for clustering.*

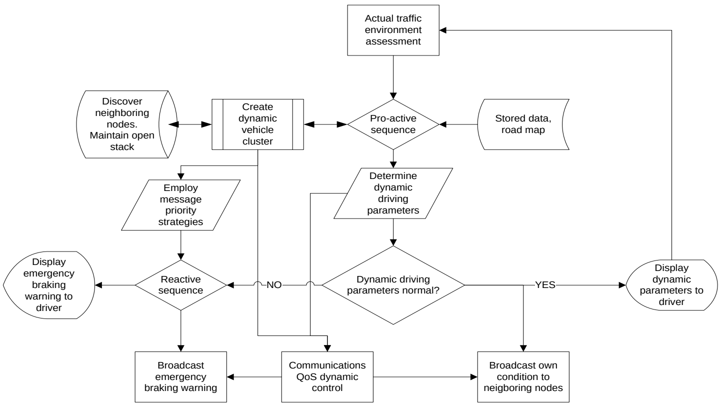

Fig. 2.
Vehicle clustering strategy and associated algorithm

The weighted control function is used to dynamically estimate and control the safety conditions in a given cluster, of given dimensions. This process results in the information provided to drivers (speed and headroom to their leading vehicles), representing the *pro-active sequence of the strategy*. The control function is based on vehicle speed, cluster's density of traffic and acceleration. If one of the alarm conditions is reached, then the algorithm should broadcast an emergency braking warning (the *reactive sequence of the strategy)*: (*i*) - receiving a relevant emergency braking alarm message from leading vehicles, (*ii*) - detecting deceleration/speed rapid variation, (*iii*) - detecting rapid variations in vehicle's horizontality or horizontal angle.

The algorithm may act in the following sequence:

- *read vehicle position; determine limiting speed due to road curvature (electronic map) - equation (13);*
- *discover/determine the number of neighboring vehicles that fit in the local cluster according to rules and reject other received vehicles that should not belong to cluster; isolate and reject vehicles running in opposite direction; perform intra-group networking to support communications;*
- *determine optimal length of the cluster l_c by computing the distance to the most remote neighboring node within the defined cluster; allocate messages priorities according to distances to neighboring nodes;*
- *compute average headroom in the cluster (equations 11,12);*
- *compute and evaluate the logical weighted control function components for safety speed limit and headroom; - determine recommended speed and average headroom in the cluster, based on computed WF:*

$$\begin{aligned} V_{WCF} &= \min\,\{v_m \vee v_{RC}\} \\ d_{WCF} &= \max\,\{d_F^p \vee d_{ACDA}\} \end{aligned} \tag{14}$$

- *display to the driver the computed (recommended) speed and headroom values V_{WCF}, d_{WCF};*
- *compare control function parameters to imposed thresholds:*

$$V_{WCF} \geq \theta_v;\ d_{WCF} \leq \theta_d \tag{15}$$

- if any alarm thresholds θ_v, θ_d in (15) is reached, warn the driver regarding unsafe driving conditions; display warning only if:
- driver did not previously take cautious measures by reducing speed or headroom;
- there is still enough time to collision or there are too frequent changes between alarming and non-alarming states (i.e., the vehicle is driven at the limit of the potential dangerous conditions) - this contributes to reducing driver stress;
- if at least one of the emergency conditions (i) to (iii) is triggered, then warn the driver of emergency braking and broadcast emergency message to relevant nodes in the cluster.

5. Analysis of Communication Efficiency

In this section a brief analysis of usable VANET protocols, taking into account the radio environment, is provided. The study is performed both for urban and extra-urban environments.

5.1. Influence of Traffic Density over Network Connectivity

Traffic density is an important factor influencing network connectivity and QoS. In low traffic densities, network connectivity has frequent interruptions, due to larger distances between communicating nodes (vehicles). Therefore, the communication protocols should be able to memorize messages and forward them when possible. However, in low traffic densities safety is higher, as no close neighboring vehicles are surrounding the central node. Consequently, the pro-active strategy (recommended safety speed and headroom information) ensures an acceptable level of traffic safety. Figure 3 presents the network connectivity vs. flow-density diagram.

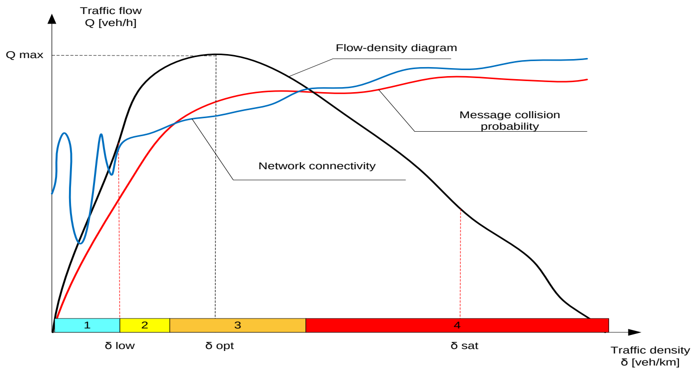

Fig. 3.
Connectivity and message collision probability in assessing traffic-related VANET performances (extra-urban environment)

Usually, geographical routing protocols of VANET are recommended for fast responsive messaging. However, in high connectivity areas, where the probability of an incident decreases with lower speeds, topological routing protocols may be also employed. In figure 3 the behavior of network connectivity and message collision probability versus the traffic density of vehicles is presented. In this respect, it becomes possible to define four interest areas (presented in colors: green, yellow, brown and red):
- *1 (green) - low connectivity / probability of message collisions, due to low traffic density and large gaps between neighboring vehicles. Vehicles move freely, with no interdependency. Average speed is high and in interurban areas the probability of message collisions and/or interferences is low; in this case, geographical routing protocols such as GeOpps (Geographical Opportunistic Routing) or VADD (Vehicle Assisted Data Delivery) are recommended, due to the fact that they allow for memorization and forwarding of messages;*
- *2 (yellow) - interdependency of vehicles' movement become dominant and average speed lowers. Vehicles are driven in platoons. Network aggregation is better, but message collisions may occur; VANET geographic routing protocols such as TBF (Trajectory Based Forwarding) or MoVe (Motion Vector scheme) are recommended, because they use beaconing and geographical/dynamic node data to forward/broadcast messages in a single hop;*
- *3 (brown) - nominal conditions. The flowing of vehicles is at peak and the road level of service is maximum. Connectivity is best and message collision probability is high. Special communication protocol measures have to be undertaken to cope with message collisions; same VANET protocols as in -2 are recommended for this area of interest; polling techniques should also be employed to maintain acceptable network throughput;*
- *4 (red) - congested traffic. Traffic flowing reaches road capacity. Vehicle speed is largely variable due to frequent stopping of vehicles. Connectivity and message collision probability are highest. Severe anti-message collision measures have to be undertaken. Polling (dynamically reduced frequency of beaconing) should be employed to lower network bandwidth overloading. Moreover, VANET protocols with dynamic content of messaging and reduced set of communication beaconing to maintain the link should be employed, e.g., FSR (Fisheye State Routing).*

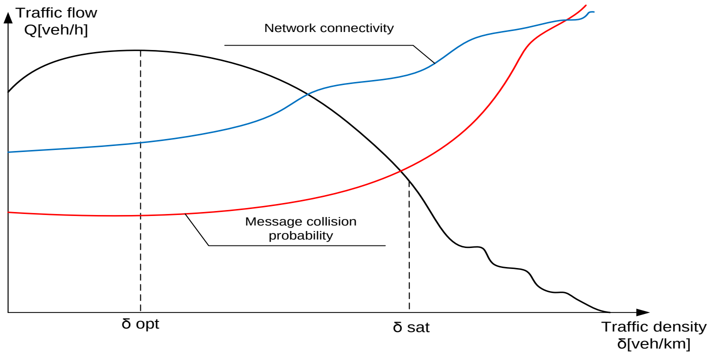

Fig. 4.
Connectivity and message collision probability in assessing traffic-related VANET performances (urban environment)

In urban environment (figure 4), the probability of message collisions is much higher, due to the presence of supplementary access points and higher traffic density. The VANET protocols should employ polling techniques combined with intensive local computation of interest parameters, a dynamic selection of messages to be broadcasted, in order to minimize the network overloading.

5.2. Quality of Service Analysis

There are some important issues regarding the radio link between communicating nodes: the frequent path disruptions caused by the high vehicles' mobility and frequent message collisions in dense traffic areas, where network throughput is affected. Therefore, the communication protocol should be able to predict link interruptions, according to vehicles' trajectory estimation and to reduce the network flooding for requests by prolonging the link durations only on selected paths.

5.2.1. Message Delay Tolerance

In the normal operation of the proposed strategy, there is a specific attribute that broadcasted messages should bear, that is the tolerance to delaying: only normal messages should be delay-tolerant and not emergency ones. Therefore, the "normal status" beaconing messages should fall under the following rules:

- *may employ routing protocols with higher communication distances;*
- *may employ dynamic polling broadcasting techniques with network throughput control in dense traffic areas;*
- *may employ communication protocols such as carry-and-forward, if network connectivity is reduced.*

"Emergency" warning/braking messages should:

- *be as short as possible;*
- *support one-hop broadcasting in dense networks and multi-hop strategies broadcasting for reduced connectivity cases;*
- *use geographical and fast-responsive routing protocols for limiting boundaries of the cluster.*

The total estimated delay Δ_{EWM} for an emergency warning message (EWM) is:

$$\Delta_{EWM} = \delta_d + \delta_s + \delta_{NP} + \xi\delta_C + \delta_E \tag{16}$$

with: δ_d - time to discover neighboring nodes / build the dynamic stack; δ_s - time to select relevant nodes, candidate for receiving EWM, according to message priority strategy (described in Section 4); δ_{NP} - total delay recorded in the network transmission process; ξ - random factor dependant on the nodes density in the network; δ_C - additional delay induced in dense radio environments, due to frequent message collisions; δ_E - time between effective event occurrence and the moment when the information becomes available for processing in the onboard unit. For a speed of *v=140* km/h, a vehicle travels 3.8m in 100 ms, and needs around $d_{FS} = \frac{v^2}{2\mu g}$ meters until full stopping, with μ the actual friction coefficient. Therefore, taking into account equation (16), the total stopping becomes:

$$d_{FS}^T = d_{P-R} + v \cdot \Delta_{EWM} + d_{FS} \tag{17}$$

with d_{P-R} - the distance traveled by the vehicle from the moment the driver notices the warning message until he/she triggers the braking. For collision avoidance, the condition is that the overhead from the leading vehicle is:

$$d_{FS}^T < d_F^p \tag{18}$$

Concluding, the maximum EWM delivery time shall be no greater than $\frac{d_F^p}{v}$.

5.2.2 Beaconing Frequency versus Capacity

In normal operation (no EWM beaconing), the main problem is to keep under control the network overload with an adequate message beaconing policy. Li, Y. showed that, in order to minimize the air time overhead, longer frames are preferable, and gave an estimation of the number of vehicles that can simultaneously co-exist in the coverage area of a single link radio system (table 1 below).

Table 1
Network capacity over maximum number of frames sent

Duration of payload [μs]	Minimum overhead ratio [%]	Maximum number of frames sent
98	100	234
196	50	156
294	33.3	117
392	25	93
490	20	78
588	16.7	67

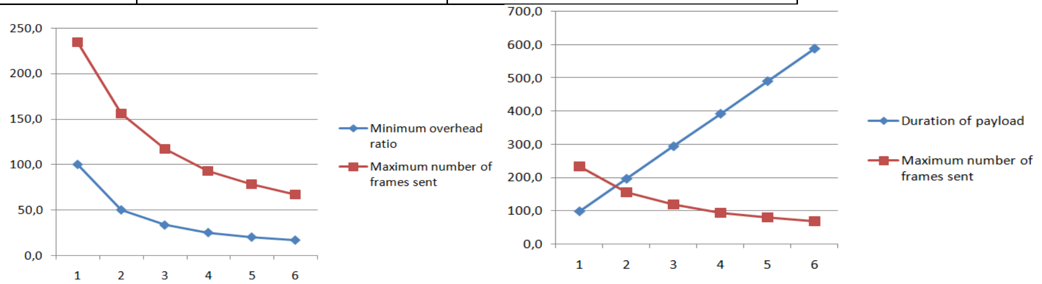

Fig. 5.
Parameters for beaconing frequency analysis

For the presented CCWS strategy, the objective is to maintain the vehicle driver dynamically informed, so key metrics should include beacon delivery ratio, number of consecutive message lost between pairs of vehicles, reliability, overhead, speed of data dissemination, and reception probability. As a larger communications range potentially increases the number of nodes contenting for the channel, which may significantly degrade the chance of successful packet delivery, the strategy should make use of local clustering algorithm to limit the boundaries of participating nodes at a certain domain, maintaining in this way the control of packet collisions.

6. Conclusions and Future Research

The paper proposed an approach for a pro-active, cooperative cruise control strategy for improving traffic safety on highways. The strategy employs local vehicle sensing of dynamic parameters and cooperative cruise control messaging with different communication protocols in DSRC. A preliminary analysis on the network connectivity and influence of traffic density has also been performed. The next step will be to verify the components of this strategy within different physical network environments. Measurement of communicating nodes density in different (urban and extra-urban areas) is under development. As an initial support, computer modeling and simulation will be the primary tools for verifying the research results.

A SURVEY ON VEHICULAR AD-HOC NETWORK COMMUNICATIONS EFFICIENCY IN DENSE URBAN TRAFFIC SCENARIOS

Marius Minea[1], Maria Claudia Surugiu[2], Ion Nicolae Stăncel[3], Badescu Iulian[4]
[1,2,3,4] Telematics and Electronics for Transports Department,"Politehnica" University of Bucharest - Transports Faculty, Bucharest, Romania

Abstract: Nowadays vehicular technologies are heading towards safety thru information exchange and autonomy. Vehicular Ad-Hoc Networks (VANET) have been recently developed for traffic safety and information transmissions in the idea of eliminating the need of a fixed infrastructure network. However, their efficiency in very dense urban traffic scenarios is still arguable, due to frequent message collisions, reduced throughput and other quality of service - related problems, encountered when traffic density exceeds certain thresholds. This paper presents a survey on mobile VANET efficiency in these conditions, where the radio environment is affected by the large number of mobile nodes and also by numerous local WiFi access points. A case study for some congested junctions in Bucharest is used to analyze the channel utilization in IEEE802.11 standards. An algorithm to improve the efficiency and service quality in vehicular communications is proposed. A-VANET, or Assisted-VANET, is the combined communication technology introduced by this paper, in order to ease the transfer of non-critical messages in dense vehicular scenarios.

Keywords: VANET protocols, vehicular and wireless technologies, traffic control.

1. Introduction

Recent developments in wireless communication technologies allow for the creation of a new outline for vehicular ad-hoc networks. In a VANET network, vehicles, as communication nodes, are able to share data or send messages via multi-hop pathways, using intermediary vehicles to reach a destination node. The routing protocol must find a path between the source and the destination to establish a data link. Implementing a protocol requires care in network quality of service; some applications also may need delay tolerant protocols, in order to ensure a safe transmission. By reducing the number of vehicles via which messages are sent, data traffic may be also diminished, facilitating a performance boost and eliminating network congestion. Given that it is build on vehicles routes' information, the message will be directly sent to nodes heading for the destination, thus reducing overall delivery time. Broadcast / multicast transmission is a mechanism often used to disseminate information from the source node to a destination node group. User authentication, network participants confidentiality and message integrity are the required elements for a safe messages exchange.

Some of the most important aspects in recent developments related to Intelligent Transport Systems (ITS) are those based on mobile communication between vehicles (V2V) and between vehicles and infrastructure (V2I), and vehicle (big) data processing. Recent efforts have focused on developing specific routing protocols for VANET networks in order to share and use information available in vehicles, such as position and dynamics.

However, due to the high mobility of nodes in a VANET environment, some protocols were tailored to addapt to specific applications, such as collision warning or cooperative driving. As the vehicles tend to move in platoons, concrete VANET networks are made up of groups of vehicles. Among the first applications of VANET were those to support road safety (e.g., collision warning/avoiding, cooperative driving - for fuel savings etc.) (José María de Fuentes, 2011). Other applications are pointing towards a better usage of road infrastructure, reducing traffic congestions and offering faster and safer routes for drivers. Typical support applications for road safety may be grouped into three main categories: i) driving assistance (navigation, cooperative collision avoidance, lane change assistance), ii) information provision (e.g., on speed limits) and iii) warning (on potential accidents, on obstacles on the road or providing warnings on traffic conditions) (Xiaodong Lin, 2008). All the above imply direct communication between vehicles, allowing for rapid information transmission, with as few delays as possible.

2. Related work

In (Blum, 2004), the authors describe an architectural model of security for VANET designed to counter the so-called "intelligent collisions" (i.e. collisions between messages that were caused intentionally). This is a type of attack, but building a robust architecture requires to envisage measures against possible attacks. The authors also propose using PKI (Public Key Infrastructure). Gerlach, (M. Gerlach, 2005) illustrates security concepts for automotive networks. Hubaux (Y.- C. Hu, 2003) looks on security from another perspective and focuses more on concepts of privacy and secure positioning. He points to the importance of a compromise between accountability and privacy and introduces the notion of Electronic License Plates (ELP), meaning the usage of single electronic vehicle numbers. Parno and Perig in (Perrig, 2005) explain some of the attacks that may occur in VANET sites. El Zarki (Stefan Saroiu, 2009) describes the specific infrastructure for VANET sites and briefly mentions some security issues and possible solutions.

The employment of digital signatures is discussed in (Meinel, 2002). The systems responsible for transportation and generation of data before it is transmitted may present physical security issues in a VANET environment.

[1] Corresponding author: marius.minea@upb.ro

Given the important benefits brought by intercommunication between vehicles and the existence of a large number of vehicles worldwide (around several hundred millions), it is obvious that this type of communication will become extremely popular. Security is one of the challenges that arise in these circumstances; for example, it is essential that information of utmost importance cannot be inserted or modified by an attacker; the system also should be able to determine the degree of responsibility of drivers, and at the same time, to protect the identity of possible drivers and passengers (Ram Shringar Raw, 2013). Although these problems seem similar to those encountered in other types of communication networks, they imply features that make them unique. Thus network size, vehicle speed, relevance of geographical location, sporadic connectivity between vehicles makes security in VANET networks a challenge that needs robust solutions. Vehicles are the interconected nodes in a VANET, provided they are equipped with specific onboard units (OBUs). Vehicles may be private (owned by individuals or companies) or public (e.g., means of transport, police cars, fire trucks etc.). The OBUs may belong to the government or a private sector provider. Considering that most VANET nodes consists of moving vehicles, network dynamics is characterized by high mobility and sporadic connectivity. Unlike traditional ad-hoc networks, in VANET the vehicles provide a large amount of traffic information, with significant bandwidth consumption. The size of VANET networks (M. Gerlach, 2005) is another feature to be taken into account. However, communication will take place locally, thus partitioning the network and making it scalable.

3. Study area and data collection

One of the most common types of charts is aimed at traffic characteristics during a peak period, limited from 60 to 90 minutes.

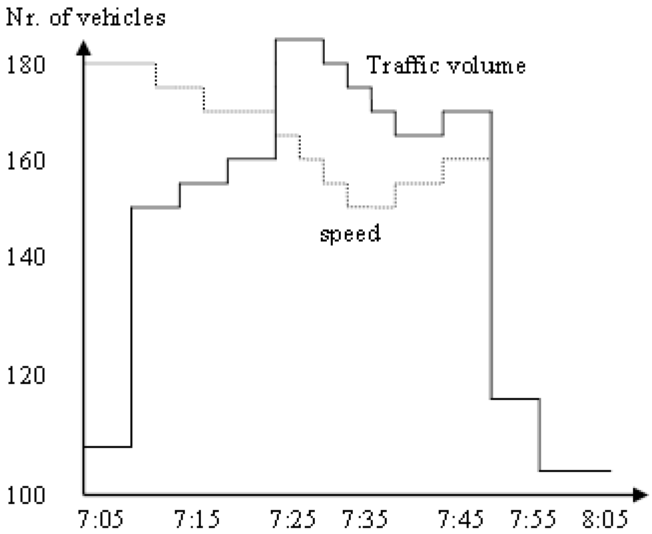

Fig. 1.
Traffic volume and speed variation in a 60 minute time slot located during peak traffic conditions

An inverse correlation between the speed and volume of traffic at speeds over 50 km / h, is generally observed. This is explained by the increased distance between vehicles on call duration due to increase response time due in particular to one of its components, the effective deceleration. Simultaneous growth on very small intervals of time, speed and traffic volume is explained by the existence of a relatively empty road that allows temporary occupation proportionality between these two factors. In current practice it often appears to flow studies the need to assess, on a scientific basis, the number of vehicles arriving in a particular area, at an intersection or into a parking lot. Subordinated to a certain frequency of unforeseen conditions, the number of vehicles arriving at a certain point in a given time, adheres to a Poisson distribution:

- each driver handles the vehicle independently of other vehicles;
- the number of vehicles that reach a certain point in a certain amount of time, is independent from the the number of vehicles passing at any other time intervals.

Distribution that meets these conditions is of a type:

$$P\ (n,q,T) = \frac{(qT)^n \exp(-q \cdot T)}{n!} \tag{1}$$

where: P (n, q, R) is the probability of n arrivals in T seconds, the value of q is the vehicle per second flow;
The working system using the Poisson relationship enables the development of charts for each value $q \cdot T$, representing the average flow, which have in abscissa different values of n (the number of incoming vehicles) and the probability

value P.

4. Proposed Model

Until now, studies on the VANET networks have focused on methods of communication based on the IEEE 802.11p, which forms the WAVE standard. IEEE 802.11p provides data rates ranging from 6 Mbps to 27 Mbps radio transmission over short distances, around 300 m (N. Wisitpongphan F. B., 2007).
Recently, the use of cellular technologies represents an alternative to IEEE 802.11p based on VANET. An important role is standardizing the most advanced broadcast / multicast services. The use of the third generation mobile communications system, called Universal Mobile Communication System (UMTS), has been used in the draft cooperation Cars (Car Co) (Project Cooperative Cars)

Table 1
Illustrates update rate, the minimum distance and maximum delay of messages according to the nature of services

Service	Maximum distance	Maximum delay	Update rate
Safety Recall Notice	400m	5s	-
Vehicle Diagnostics	500m	5s	10Hz
Wrong Way Driver Warning	500m	1s	10Hz
Emergency Vehicle Signal Preemption	1000m	1s	1Hz
Approaching Emergency Vehicle Warning	1000m	1s	-

It can be seen that the warning message for emergency traffic can be delivered in less than a second.
GSM / UMTS - is an international standard for private mobile communications. UMTS enables multi-media mobile communication and data at currently sufficient speeds, representing a good solution for UTC / PTM systems and transport equipment. Currently, UMTS networks can offer "personal navigation". The network service provider is able to precisely locate and provide UMTS terminal location selected services - such as for example the route to the nearest parking lot, gas station etc. Essentially, services are provided by the core network, a PABX digital type which provides data packet switching between different destinations.
Long Term Evolution (LTE) succeeds to increase the speed and capacity of mobile networks so that downlink speed can reach up to 100 Mbps and the uplink up to 50 Mbps, this for a 20 MHz band. LTE technology is a step that precedes 3.5 G and LTE Advanced, the fourth generation of radio technologies (4G). LTE objectives envisaged were: transfer speed, transfer and latency greatly enhanced emphasis on simplicity, flexibility spectrum to which was added to the increased capacity and a lower cost per bit. LTE provides for down-link rates of 300 Mbps, and the maximum up-link rate of 75 Mbps, the latency of less than 5 ms (Noha M. Sadek, 2015)

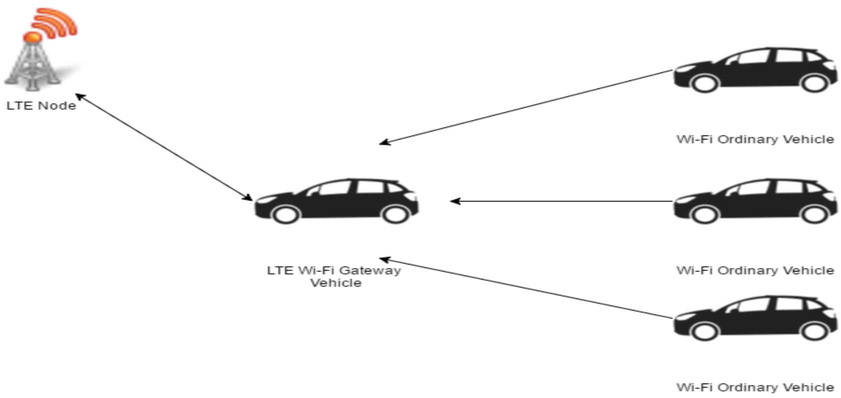

Fig. 2.
VANET-LTE network architecture

GPRS introduces transport services Packet Switched flow rates from 14 kbps to 170 kbps maximum. Basically GPRS is a standalone packet switching network plus the GSM network. GPRS interoperates with the GSM infrastructure at BSS subsystem level base stations and database from the NSS network subsystem (HLR, VLR, AUC). GPRS collects traffic data and GSM voice traffic remains switched by MSC. The data is transmitted via GPRS in fixed-length packets. Each packet contains the destination address in order to be routed to GPRS nodes. Changing the radio interface is given by the introduction of adaptive channel coding. This means that the protection of data varies in time, depending on the state of the radio channel. To a first approximation, the flow of a packet data system using error detection and retransmission is:

$$Throughput = (1 - BLER) * code\_data\_rate \text{ [b/s]} \quad (2)$$

Where BLER is the block error rate and code_data_rate is raw data rate in b / s for the physical channel. However, equation (1) does not take into account complex control procedures and error correction taking place in the RLC / MAC fields (Radio Link Control / Media Access Control) layer of the GPRS air interface (Noha M. Sadek, 2015).
The analysis presented in this paper can be used to achieve rate adaptation algorithms. As in other data transmission systems, the most important variables influencing the choice of coding scheme is measured channel quality of transport-interference ratio (C/I). In addition to the C/I channel, the size of the packet and channel fading characteristics play important roles in the coding scheme selection.
System flow is defined as the amount of data transferred over a period of time t, when t tends to infinity (Noha M. Sadek, 2015), (Konstantinos, 2011) (GHEORGHIU Razvan Andrei, 2015).

$$\mathrm{E[throughput]} = \lim_{t \to \infty} \frac{\mathrm{N(t)} \times \mathrm{packet\_length}}{\mathrm{t}} \; (\mathrm{kb/s}) \quad (3)$$

Where N (t) is the number of packets transmitted in the system, and packet_length is the length of the packet.
The number of packets N (t), divided by the time t is equal to the inverse of the predicted service packages, as t approaches infinity. To calculate the packet transmission delay, total delay segment can be divided into several components from channel assignment to the final confirmation (Noha M. Sadek, 2015):

$$T = T_{assig} + T_{tx} + T_{error\_correction} + T_{final\_acks} \quad (4)$$

Where T_{assig} is the length of time for the assigning procedure channel transmission and processing, TTX is the time of transmission, Terror_ correction is time error correction including retransmission T_{final_ack} is the last ACK (Acknowledgement) and ACK control and processing message transmission time (Konstantinos, 2011) .

Table 2
SNR values

SNR value [dB]	**Signal strength**
> 40	Excellent
25 - 40	Very good
15 - 25	Good
10 - 15	Low
5 - 10	Very low

For this study, 3 major intersections from Bucharest where chosen to simulate the A-VANET algorithm message distribution (Fig.3). The lane distribution was simulated using Synchro 8. In this way, we highlighted the number of lanes in this 1987 m (approx. 2 km) road section.
From left to right, these 3 intersections are highlighted with a specific set of values. These values represent the number of vehicles that cross this specific road segment in 1 hour, on each lane, and on every travel direction. The selected time slot (7:05-8:05) is considered a peak hour, when the morning commute takes place, from the west side of the city to the east side.

Fig. 3a.
Lujerului intersection

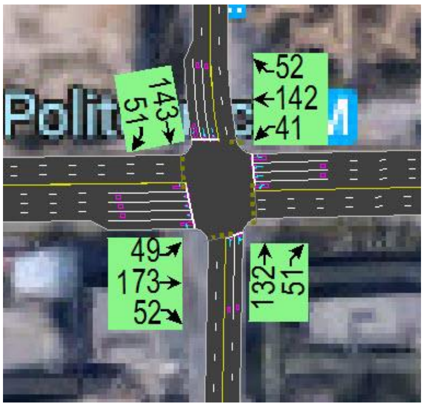

Fig. 3b.
Apaca intersection

Fig. 3c.
Leu Square intersection

The Poisson distribution is commonly used to determine the probable number of vehicles in a guided intersection, presuming the number of vehicles using the left relationship to be stored during a traffic lights operation cycle or knowledge of the number of vehicles arriving within time in a parking area at peak traffic circulation. In the measurements performed in the considered intersections a speed variation depending on traffic density is observed. If the density increases, interference phenomena occur between vehicles and the speed decreases until there are approximately 100 vehicles per kilometer of road or 1 vehicle to 10 meters.

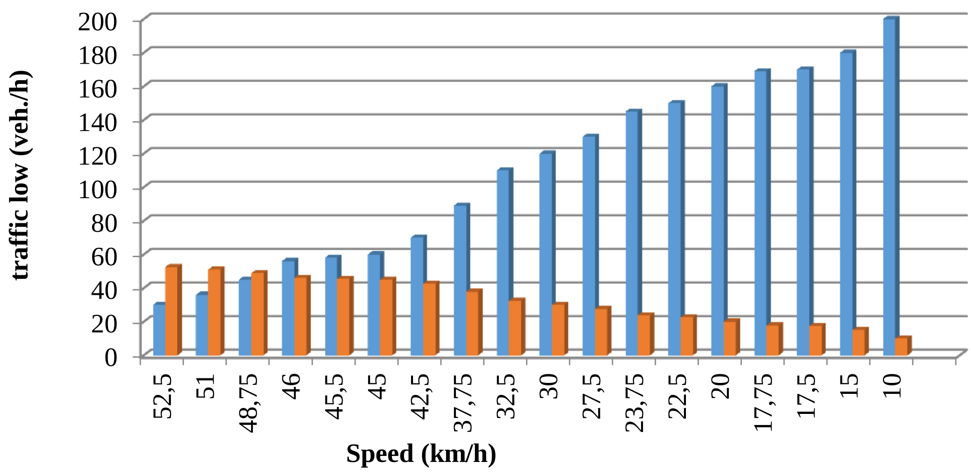

Fig. 4.
Traffic volume and speed variation

In the study conducted, the level of service for each intersection throughput depending on the average speed in a 24-hour period was revealed (Figure 6). The LOS are shown after a color code presented in Table 6. As it can be seen, urban congestion is evidenced by a maximum average speed of 40 km/h, restricted to the lower level B, and a minimum value of 7 km / h, enclosed at level F.
Peak times can be seen, where traffic congestion is present. Large timeframes for crossing the 3 intersections and therefore a much slower travel time of the road section are highlighted. Thus, a chart which shows the necessary travel time to cross the length of the road sector in a 24 hour period is shown (Fig. 7).The morning and afternoon commutes are revealed.

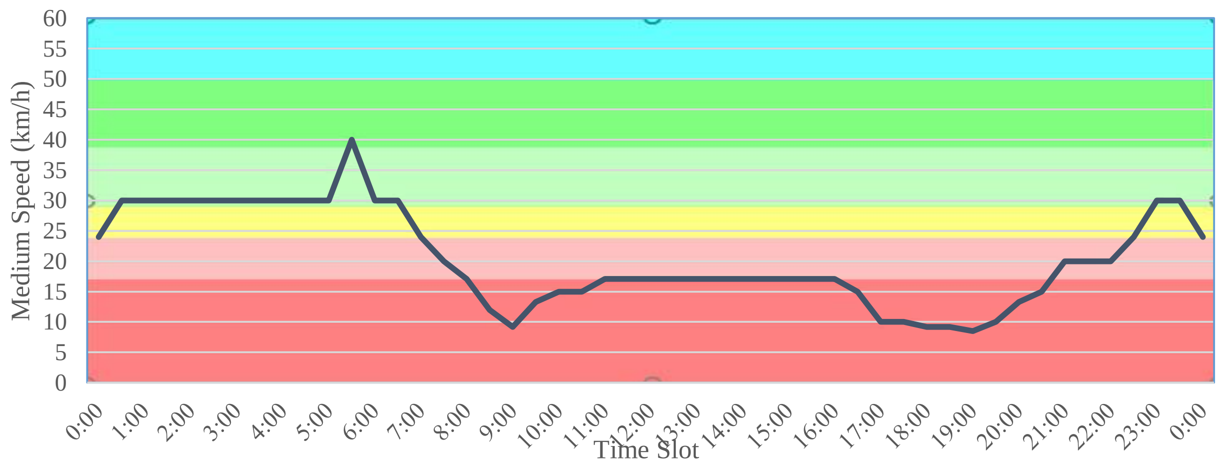

Fig. 5.
Variatia vitezei medie de circulatie in 24 ore cu evidentierea nivelurilor de serviciu

Table 3
Legend LOS

F	E	D	C	B	A
17-1km/h	22-17km/h	28-22km/h	39-28km/h	50-39km/h	>50km/h

Source (Das A. K., 2014)

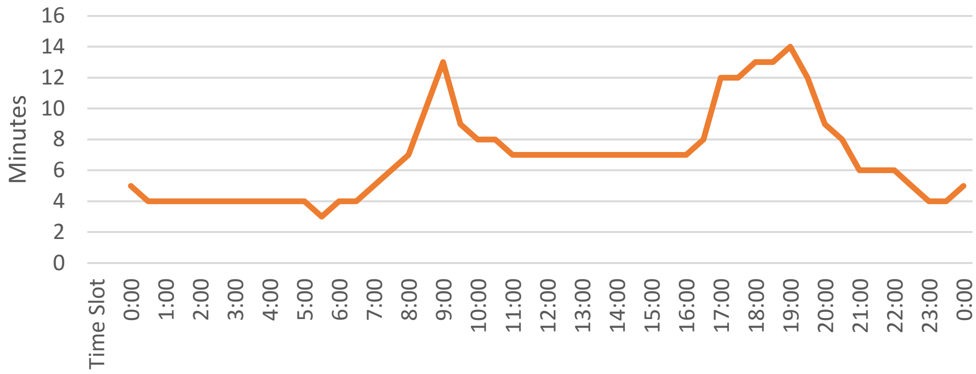

Fig. 7.
Travel time to cross the length of the road sector in a 24 hour period

If the number of vehicles per hour increases over 1400, but due to a traffic jam caused by a single damaged car or a parked car, quite often the case in urban transport, the vehicle row road speed drops drasticly . Especially during peak hours changes are made quite suddenly within relatively short time slots, within even a minute .
The present paper proposes a new model for a message sent over V2X (V2V, V2I) networks. The mode of transmission has been conceived in a secure manner. A roadside unit (RSU) issues a unique key, which is determined by its geographical position. When a node (vehicle) travels through the operating range of the RSU, a message containing a query field (ID area) will be sent to the RSU (table 3).

Table 4
The message structure

ID user	**ID area**	**Timestamp**	**Sensor data**

- ***ID user*** – identifies a user - for example, a vehicle (4 bytes);
- ***ID area*** – identifies geographic area based on GPS coordinates (6 bytes = 3 bytes alt. + 3 bytes long.).
- ***Timestamp* –** Represents the time at which the sensor reading was retrieved. To ensure time synchronization between different devices, the time is set to the existing ITS infrastructure for data coming in block (8 bytes).
- ***Sensor data* –** represents any kind of measurements performed on any sensors from the road infrastructure (1…n bytes).

The simplicity of this format allows for data storage over most types of databases. The message structure can be improved, depending on the chosen protocol, by adding predefined fields: number of packets sent, number of packets received, number of unsent packets and the residual capacity of the channel for ISM band (table 4) (A.J. Ghandour, 2013), (S. Ibrahim, 2015).

Table 5
Time and packet components

Timestamp	**TTL**	TX_r^c	RX_r^c	TNX_r^c	C_r

Where Timestamp – 8 bytes; TTL – 10 bytes; TX_r^c – 10 bytes; RX_r^c – 10 bytes; TNX_r^c – 10 bytes; C_r - 8bytes*nr.Selected channels.
Nr. of total transmitted packets (A.J. Ghandour, 2013):
$TX_r^c = \sum_{i=1}^{N} tx_{r,i}$ (4)
Nr. total received packets (A.J. Ghandour, 2013):
$RX_r^c = \sum_{i=1}^{N} rx_{r,i}$ (5)
Nr. of total unsent packets (A.J. Ghandour, 2013):
$TNX_r^c = \sum_{i=1}^{N} tnx_{r,i}$ (6)
The channels residual capacity or ISM band (A.J. Ghandour, 2013):
$C_r = C \cdot (1 - \omega_r)$ (7)
where ω_r - workload for channel from the ISM band

Confidentiality and data integrity is ensured by secured connecting devices used in the communication between users. In order to provide access control to the database to reach the information of interest, the user must authenticate as showed in Figure 1. Availability is ensured by creating authentication keys for each user, accessible at any authorized manner. The authenticity of the transmitted information is determined by the presence, or absence of authorized signatures. The scheme shall meet the following criteria:

1. The receiver shall verify the identity the transmitter claims to have;
2. The transmitter shall not deny that it is the author of the message;
3. The message shall not be prepared by the receiver.

Next, a final form of the message structure, depending on the communication protocol, is reached. In order to avoid saturation of an AP with authentication messages and information exchange, a TTL (Time To Live information) is included in the message structure. It represents a mechanism that limits the lifespan of the message, until it is received and aproved. When a RSU (source) or vehicle (source) identifies more callers in the vehicular network, it will redirect them to the closest neighbors, depending on the type of message (emergency cooperative, multimedia) (Fig.3). The final message structure is presented below table 6 (A.J. Ghandour, 2013), (S. Ibrahim, 2015):

Table 6
Message structure

Communication Protocol	**Message Type**		**Message Certificate**		**Digital Signature**
Timestamp	TTL	TX_r^c	RX_r^c	TNX_r^c	C_r

Where Communication Protocol – 1 byte; Message Type – 1 byte; Message Certificate – 125 bytes; Digital Signature – 56 bytes; Timestamp -8 bytes; TTL – 10 bytes; TX_r^c – 10 bytes; RX_r^c – 10 bytes; TNX_r^c – 10 bytes; C_r - 8bytes*nr.Selected channels.

The currently presented algorithms focuses on the idea that information is transmitted between cluster or groups of vehicles, rather than individual vehicles. In each group, one or more vehicles, chosen based on their positioning will transmit data to their neighbors (who are still groups). A defining criterion in forming groups is geographical positioning. Thus, considering the information received from the GPS system and dividing the area into cells, a vehicle can determine whose group belongs to at time (area division in cells is predetermined in advance). Each vehicle processes all events locally, both those directly observed and those reported by other vehicles, before taking a decision on the event. In each group there are one or more leaders who distributes messages. One way to check the received data is to compare it to other received information from other sources about the event. Thus, to test the validity of messages, and that of the source, it is required that during the message routing, intermediate nodes must sign over the signature of the previous transmitter. A invalid signature at any time will invalidate the message reaching the final receiver.

The main aspects that underlie the exposed solution are: vehicle position when transmitting messages, the time at which the emission is happening and existing certification authorities in the area at the start of the transmission. If a validity request regarding a message that has reached a particular vehicle is processed, the next fields are checked: the message type and the attached digital signature. If the message has been validated by the RSU, it will return a response to the destination vehicle. If the signature is valid, the answer is positive; otherwise, the answer is negative (rejected).

To prevent an attack, this confirmation message contains a digital signature. If an attacker disrupts a message, the vehicle may notice this purpose, and then verification is performed with a public key emitted by the RSU, based on the received digital signature. (Fig.3). Certificates are temporally / spatially limited, which allow them to be used in a certain geographical area or in a pre-determined period of time. The basic idea is that if a user wishes to actively participate in a VANET network, he/she must make use of an area identification device in the OBU. Each device is an assigned identifier and a certificate. During initialization, the device will be recorded with the user's account; user information shall be maintained at the service provider and shall not be stored in the onboard unit. When a user enters a region and wants to use services from that area, he/she uses the earlier mentioned device. The request message will be encrypted using the providers' public key, thus obscuring the device's identity for occasional "unauthorized listeners". Users get a certificate only when they need a service. The certificate revocation is done automatically when the message lifetime expires or when they exit the zone borders. For each new certificate the service provider checks if the previous certificate has been revoked. If so, the new certificate may be issued.

Due to the dynamic property of VANET networks, message queues can form. For example, signing messages is via the access point in close proximity, but when the vehicles travel at a high speed or change their route, the signed message will not be able to get back to the vehicle which issued it because it emerged from the coverage of the access point. However, the message will be sent, so it will be stored in a message queue, and will subsequently be sent when the vehicle that issued it is in the coverage of another secure access point. The message routing can be done in two ways:

- directly, in case the destination is within range of the source;
- through intermediate nodes (vehicles), if the destination is not in the source coverage area.

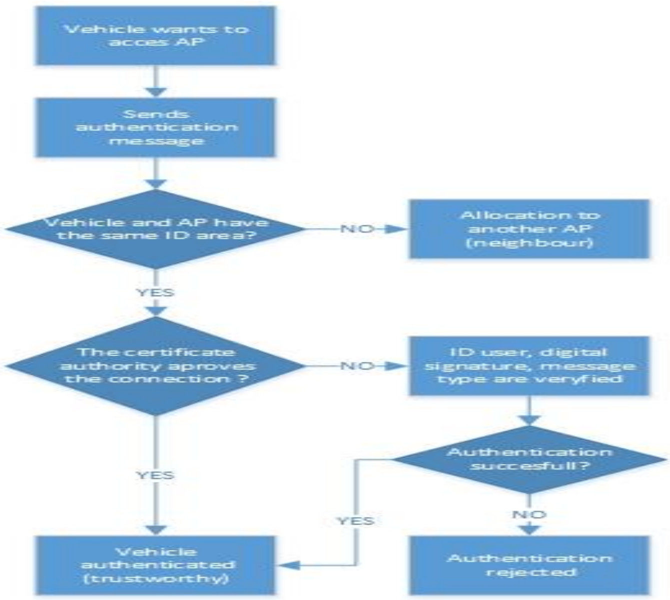

Fig. 6.
Vehicle authentication flow

5. Conclusion

The study focuses on the idea that information is transmitted between groups rather than between individual vehicles. In each group, one or more vehicles, selected on the basis of their positioning will transmit data to their neighbors (who are all groups). A defining criterion in forming groups is geographical position. Thus, considering the information from the GPS system and dividing the area into cells, a vehicle can determine the group that belongs to at a certain time (dividing cells is a predetermined area in advance). Each vehicle processes local events, both those directly observed and those reported by other vehicles, before taking a decision on the event. In each group there are one or more leaders who distribute messages. One way to check the data received is a comparison to other information received from other sources about the event. Otherwise, to test the validity of messages and the source it is required that during the message routing, intermediate nodes signature to sign over the previous transmitter. A signature invalid at any time will invalidate the message reaching the final receiver. The main issues that underlie the solution presented are: the vehicle position when transmitting the messages, the time at which the emission is happening and existing certification authorities in the area at the start of transmission.

Compared to a simple unsecured message transmission (section 4, tables 4 and 5), the proposed solution (section 4, Table 6) will require an additional network load. The additional amount of data introduced by the proposed security algorithm is due to added digital signatures and counting received and undelivered messages. The secure transmission of messages between vehicles in traffic is made depending on whether an entity for certification is present in the area, and depends on distance between vehicles which want to communicate, if the destination node is within the transmission range; otherwise, there is need to select a route that includes several hops in the transmission of messages (Section 4, Fig.3).

The next steps will be to implement the algorithm and to test it in a simulated, or experimental environment, in order to determine the quality of service parameters in the newly, more secure format. This will ensure the algorithm does not affect messages that need rapid delivery to destination.

BIOMETRIC IDENTIFICATION SYSTEMS IN FUNCTION OF TRANSPORT SAFETY BY APPLYING CVQ COMPRESSION METHOD

Mirko Čorić[1], Anita Gudelj[2], Tomislav Bubalo[3]
[1,2] University of Split, Faculty of Maritime Studies, Ruđera Boškovića 37, 21000 Split, Croatia
[3] University of Zagreb, Faculty of Transport and Traffic Sciences, Vukelićeva 4, 10000 Zagreb, Croatia

Abstract: Generally, fingerprint, face and iris recognition occupy a large place in biometric identification, and they are among the most popular biometric methods. Popularity of biometric identification is growing in all areas of transport, such as maritime, air and road transport. All these biometric methods operate following the same principle: creation of unique digital templates that are extracted from data such as iris, face and fingerprint images. Specially designed algorithms are used for creation of unique digital templates. Future tendencies and politics suggest usage of real fingerprint, face and iris images instead of templates. Biometric identification systems in transport often require storage and transmission of images, and therefore images should be compressed in order to save resources. This paper explores and analyses effects of Classified Vector Quantization (CVQ) compression method against fingerprint, iris and face images. Grayscale images from public databases are used in the experiment. Results show that CVQ is not equally effective against all three types of images at the same bit rate level because some types have different image properties in terms of image edges and abrupt transitions between pixel values. Advantages over ordinary Vector Quantization (VQ) are pointed as well.

Keywords: biometrics, identification, CVQ, compression, transport, safety.

1. Introduction

Biometric identification is used in security and access control applications in order to identify persons based on their physical characteristics that can be checked on automated basis. Biometric identification technologies occupy larger and larger place in many areas of transport and traffic security lately, especially since the 9/11 event (Amoore, 2006; Wikipedia, 2016). Fingerprint, face and iris recognition are considered to be among the most widespread and most studied biometric modalities (Woodward et al., 2003; Daugman, 2004; Biometrics.gov, 2016; Bača et al., 2012). Biometric technologies are being adopted in different areas of transport constantly. Governments and international organizations are focused on evaluation of the transportation related security risks. Many of these initiatives require integration of biometrics to authenticate the identities of individuals with access to critical cargo, secure areas of transportation facilities, different traffic areas and associated information technology systems. For example, The Tocumen International Airport in Panama operates an airport-wide surveillance system using hundreds of live facial recognition cameras to identify wanted individuals passing through the airport (ihsairport360.com, 2014). Few years ago, Spanish has installed multi-biometric identification system in two of its largest airports to identify persons on the airport access-control kiosks (findbiometrics.com/spanish-airports-install-multi-biometric-security-systems/, 2010). Furthermore, Canadian National Railway (CNR), the fifth largest railroad in North America, is integrating fingerprint biometrics into its Speedgate control system which was designed to monitor commercial truck access to CNR's inter-modal transfer facilities located throughout North America (Bragdon, 2011). Another example is American Coast Guard which is using portable iris scanners in order to quickly identify smugglers or suspected migrants at sea (Securing our borders: Biometrics at sea. Coast Guard Compass, 2011). There are numerous other examples of the use of biometric identification in various transport areas. In fingerprint, face and iris identification systems (further in text referred just as biometric identification systems), large amounts of biometric data needs to be stored in databases, as well as often sent via different communication channels (e.g. Internet) in order to exchange data with other parts of the systems. Majority of existing biometric identification systems do not operate with real biometric data (real fingerprint, face and iris images), but instead use unique features that are extracted from real biometric data using specific algorithms. These unique features are often called digital templates or codes, and they uniquely represent each and every individual (Jain et al., 2007). Simpler and more desirable solution would be the use of real biometric data (real fingerprint, face and iris images) instead of digital templates since intermediate steps that include involvement of specific algorithms are avoided in that case. Moreover, different politics advocate for the use of real biometric data instead of digital templates in order to achieve interoperability and vendor neutrality (National Institute of Standards and Technology. U.S. Department of Commerce., 2013). Also, storage of extracted features (digital templates) is considered to be non-reversible biometric data, meaning that the original iris, fingerprint or face image cannot be restored from extracted features (Wayman et al., 2005). Because of these flaws using only digital templates on the one hand, and the fact that storage and transfer of real raw biometric data (fingerprint, face and iris images) consumes a lot resources on the other hand, a solution can be found in the use of real but compressed biometric data (compressed fingerprint, face and iris images). Experiments already showed that this solution is possible, and that recognition accuracy is not significantly affected (Funk et al., 2005; Daugman and Downing, 2008; Mascher-Kampfer et al., 2007). Previous studies showed that Vector Quantization (VQ) compression approach stands side by side with other standard techniques used for compression of biometric data images, and even outperforms them (Elad et al., 2007; Mascher-Kampfer et al., 2007; Kekre et al., 2010; Matschitsch et al., 2007). In this paper more advanced type of VQ is used

[1] Corresponding author: mcoric@pfst.hr

called Classified Vector Quantization (CVQ) where the classification of blocks of pixels (vectors) is based on edges (Ramamurthi and Gersho, 1986). Compared to ordinary VQ, CVQ is much faster in terms of coding time, which directly affects the overall recognition procedure (Čorić et al., 2016). If compared with each other, mentioned biometric data (iris, face and fingerprint images) are quite different in terms of image properties (different levels of transitions between neighbouring pixel values, different contrast levels, etc.). This work explores and analyses differences in image quality between iris, face and fingerprint images after being coded and compressed using CVQ . The paper is organized as follows. Next chapter briefly describes CVQ compression method, third chapter describes methodology and results, and the conclusion is given in the final chapter.

2. CVQ approach

Generally, VQ is a technique in which the block of pixels (vector) from the original image is replaced with the closest matching block of pixels (vector) from the codebook. In other words, approximation is done. It is not necessary to search the entire codebook to find the most similar approximation vector during VQ of the input vector. It is possible to select and consider only one subset of the codebook when choosing approximation vector. In other words, it is possible to classify the input vector, i.e. determine to which subset of the total codebook it belongs. Described method is called CVQ (Fig. 1).

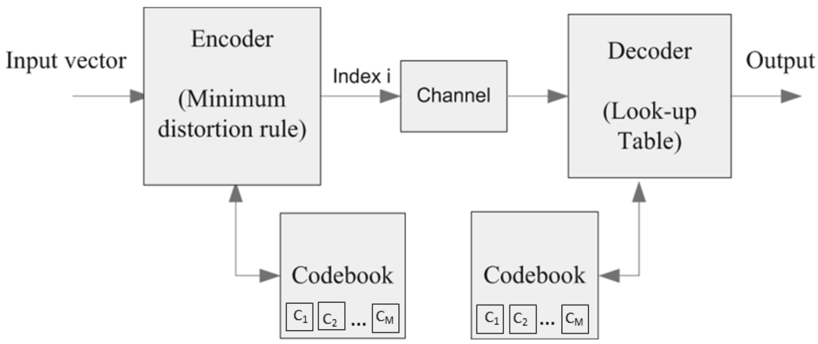

Fig. 1.
CVQ general description
Source: (Ramamurthi and Gersho, 1986)

In CVQ index (address) of the vector from the codebook consists of two parts. The first part, generated by classificator, determines the codebook C_i in which the search for approximation vector is performed. The second part of the index is the address of the code vector within each codebook. Codebooks C_i are generated so that the overall training sequence T is divided into M subsequences $T_j(j=1,2,3,\ldots,M)$ after it passes through the classifier. Afterwards, every codebook L_j of size $m_j(j=1,2,3,\ldots,M)$ is generated using one of the algorithms (algorithms designed for development of codebooks) for the appropriate subsequence only. LBG algorithm (Linde et al., 1980) is used in this work. Overall codebook is composed from all codebooks L_j. Classification of vectors from original image can be performed based upon different image properties. In the case of image compression, classification based on edges is the most common. This work uses CVQ based on the method called comparison of locally thresholded image vectors with a predefined set of binary edge templates (Quweider and Salari, 1996).

3. Methodology and results

3.1. Basic idea

VQ essentially involves replacement of the original blocks of pixels (vectors) with the closest blocks of pixels (vectors) that are placed within a codebook/s. This is called approximation. Ordinary VQ treats equally all parts of the image, while CVQ pays special attention to the edges that are located within the image. It means that edges are approximated better than the rest of the image if CVQ is used. It is one of the most important feature of CVQ since edges within the image play the most important role for the human visual impression and resolution of details. Edges can be described as lines, curves and all the image parts where sudden transitions between neighbouring pixels occur. Average images from everyday environments do not have a tendency to contain as much edges as fingerprints and iris images do (dense network of lines and curves are present within these images). On the other hand, face images tend to be more similar to average images considering their properties and amount of edges. CVQ can take advantage of this feature (increased amount of edges within images) in order to achieve better results, especially for fingerprint and iris images. Generally, codebooks contain approximation vectors that are derived from training set of vectors extracted from training original images representing the environment with which images to be compressed are related. In the case of CVQ, training vectors are classified into different edge classes first (using method from Quweider and Salari, 1996 in this work), and the separate codebook is developed for each and every training set of vectors for each and every edge class. If there is a lack of edges within the training original images, then the lack of training vectors is present within training sets of vectors belonging to these edge classes. Furthermore, if there is a lack of training vectors within a training set of vectors, codebook derived from that set of training vectors is not good enough. This is not an issue in the case of mentioned biometric images since these images contain more edges than average images.

3.2. Methodology

The same procedure was performed for all three kinds of biometric data, meaning that there were 3 test cases (fingerprint, iris and face images test case). Gray fingerprint, iris and face images were taken from available public databases on internet (advancedsourcecode.com/fingerprintdatabase.asp, 2012; pics.psych.stir.ac.uk/, 2010; phoenix.inf.upol.cz/iris/, 2009). In the fingerprint test case, 22 fingerprint images of size 248x338 pixels were taken as a training images for extraction of training vectors of size 4x4 pixels, meaning that a total of 115 258 training vectors were extracted. Extracted training vectors were classified (distributed) among 30 different classes. 28 classes refer to different types of edges, one class (mixed class) refers to all edges that are not covered by these 28 classes, and one class refers to all the vectors that are not classified as edges. Afterwards, LBG algorithm was used in order to develop separate codebooks for each of these 30 classes. Codebooks of different sizes (4, 8, 16 and 32 codewords per class) were developed for each class, therefore input vectors from original fingerprint images can be coded at different bit rates (ranging from 0.43 - 0.625 bits per pixel) using CVQ. Finally, few randomly selected fingerprint images from database were coded (i.e. compressed) at mentioned bit rate levels. Mean Squared Error (MSE) (en.wikipedia.org/wiki/Mean_squared_error, 2014) was used as a measurement of quality of coding (i.e. compression). All the steps are performed using Matlab scripts designed for this purpose. Results are presented in the next subsection. As for the iris test case, the same methodology was applied over the iris images, provided that 6 iris images of size 640x480 pixels were taken as a training images in order to achieve approximately the same number of training vectors (115 200 training vectors) as in the fingerprint test case. Again, vectors extracted from these 6 training iris images were classified among 30 classes, separate codebooks were developed for each class, and a few randomly selected iris images were compressed using the same bit rate levels as in the fingerprint test case. And finally as for the face test case, the same procedure was applied again, provided that 11 face images of size 352x480 pixels were taken as a training images in order to achieve approximately the same number of training vectors (116 160 training vectors) as in the fingerprint and iris test case. Other steps are performed as in the previous two test cases. Results for the iris and face test case are presented in the next subsection as well. Fig. 2. shows samples of training images for all three test cases.

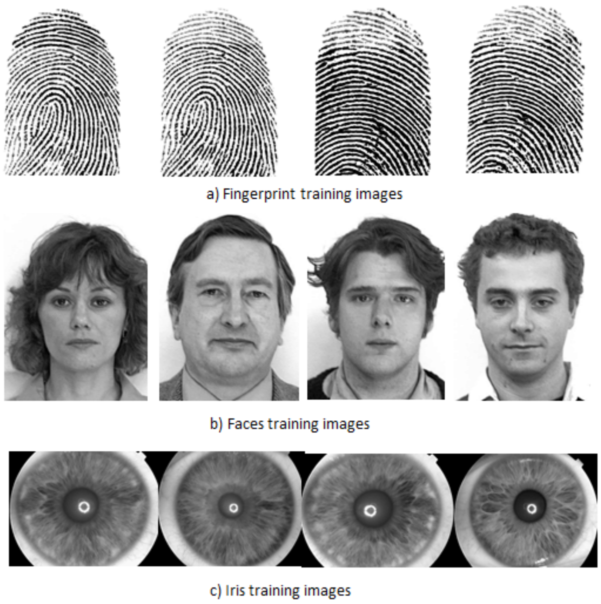

Fig. 2.
Samples of training images for each test case
Source: Public internet databases

3.3. Results

Statistics of extracted and classified vectors for all three test cases is shown in Table 1.

Table 1
Classified vectors statistic for each test case

Fingerprint test case			Iris test case		Face test case	
class	number of vectors	% of vectors	number of vectors	% of vectors	number of vectors	% of vectors
1	1406	1.23	259	0.22	209	0.18
2	3017	2.63	3146	2.73	2042	1.76
3	2392	2.09	3829	3.32	1718	1.48
4	1758	1.53	698	0.61	412	0.35
5	2983	2.60	4565	3.96	2903	2.50
6	3029	2.64	2458	2.13	1958	1.69
7	1478	1.29	211	0.18	252	0.22
8	3347	2.92	3318	2.88	2450	2.11
9	2833	2.47	3250	2.82	2362	2.03
10	1530	1.34	636	0.55	326	0.28
11	3293	2.87	4783	4.15	2731	2.35
12	3560	3.11	2391	2.08	2364	2.04
13	3854	3.36	361	0.31	63	0.05
14	800	0.70	226	0.20	85	0.07
15	1088	0.95	1478	1.28	526	0.45
16	16805	14.67	5352	4.65	1758	1.51
17	820	0.72	304	0.26	129	0.11
18	464	0.40	303	0.26	151	0.13
19	1067	0.93	1796	1.56	704	0.61
20	7564	6.60	3657	3.17	2142	1.84
21	3520	3.07	551	0.48	430	0.37
22	1828	1.60	1432	1.24	737	0.63
23	1560	1.36	1987	1.72	806	0.69
24	3094	2.70	1282	1.11	486	0.42
25	2900	2.53	1268	1.10	680	0.59
26	1543	1.35	2155	1.87	1277	1.10
27	1483	1.29	880	0.76	574	0.49
28	3258	2.84	504	0.44	409	0.35
mixed	8357	7.29	12171	10.57	9230	7.95
non-edge	23945	20.90	49949	43.36	76246	65.64

As it can be seen from the table, in the fingerprint test case 79.1 % of vectors are classified as edges, in the iris test case 56.64 %, while in the face test case 34.36 % of vectors are classified as edges. Since classes in the fingerprint test case contain more edge vectors then classes from the other two test cases, codebooks developed for the fingerprint test case contain better approximation vectors. Therefore, quality of compressed fingerprint images is better than the quality of compressed images from the other two test cases at the same bit rate levels. Several images per each test case are coded, and the average coding results for each test case are shown in Table 2.

Table 2
Average MSE for each test case

bpp	MSE for the fingerprint test case	MSE for the iris test case	MSE for the face test case
0.437	32.54	33.87	38.12
0.5	17.68	20.71	29.53
0.562	8.04	11.16	22.61
0.625	4.36	7.59	18.06

Results after compression show that iris images have reduced MSE compared to face images, and fingerprint images have reduced MSE compared to face and iris images. This means that compressed fingerprint images achieve better quality than other two types of images at the same bit rate levels. They are followed by iris images, while face images take last place in terms of image quality.

4. Conclusion

This paper examines the effect of CVQ compression method when applied over three different types of biometric data, namely fingerprint, iris and face images. In general, CVQ compression method takes advantage of large number of edges in order to enhance the quality of all the parts of the image containing the edges. Results show that among the mentioned biometric data, fingerprint images are the most suitable candidates for CVQ compression method since fingerprint images contain more edges (valleys and ridges within fingerprint images) than other two types of images. Different areas of transportation and traffic security can benefit from this research, especially ones that use fingerprint biometric systems. The value of this research increases even further due to the fact that multimodal biometric systems are the future, and that exactly fingerprint, iris and face biometric systems are the basis for the multimodal biometric systems.

[2,5] University of Ljubljana, Faculty of Maritime Studies and Transport, Ljubljana, Slovenia
[3] University of Belgrade, Faculty of Transport and Traffic Engineering, Belgrade, Serbia

Abstract: The Adriatic-Ionian macro region is one of the four Mediterranean sub-regions, recorded approximately 5.2 million of cruise passengers and 17 million ferry passengers in 2013. The study performed within the WP4 of EA SEA-WAY project covered twenty ports in six countries of the Adriatic-Ionian region and their hinterland connections assessment. The primary objective of each database is to enable a comprehensive view of data making it easier to focus on analysis. Database should have functionalities such as systematization, timelines collection and data entry into one place by using user friendly interface. For developing big databases, such as database for EA SEA-WAY project, there is a need for making a model to provide the integrity and interconnectedness data. Relational databases have dominated the software industry for a long and ERD (*Entity-Relationship Diagram*) and it is used to visually represents the relationship between database entities. Also, it is very important to decide which DBMS (*Database Management System*) to use in creating database. In this paper is presented a solution for EA SEA-WAY project database as a useful assessment tool for the ports and other stakeholders in the Adriatic-Ionian macro region.

Keywords: EA SEA-WAY, database, assessment, port, hinterland.

1. Introduction

EA SEA-WAY (European Adriatic Sea-Way) is the project co-funded by the European Union, Instrument for Pre-Accession Assistance. The general objective of EA Sea-Way Project is to improve the accessibility and the mobility of passengers across the Adriatic area and its hinterland. This improvement should be done through the development of new cross border, sustainable and integrated transport services and the improvement of physical infrastructures related to those new services. One of main challenges was to explore a better integration of urban and regional connections between ports, airports and main tourist destinations/urban areas. According to this several studies have been done.
Most experts and project partners spend the majority of their time searching relevant data and the hardest part of delivering studies was lack of information. It is the reason why project team prepared and delivered different kind of databases according to the different results to be reached through work packages. The main goal of EA-SEA Way database is to enable more comprehensive view of data related to the project activities. There is a need for easy manipulating of data and storing them into one place. That will enable quick processing and analyzing data.

2. EA SEA-WAY Project

2.1. Objectives of the EA SEA-WAY Project

The general objective of European Adriatic Sea-Way (acronym EA Sea-Way) is to improve the accessibility and the mobility of passengers across the Adriatic area and its hinterland, through the development of new cross border(CB), sustainable and integrated transport services and the improvement of physical infrastructures related to those new services (EA Sea-Way, 2016). The EA SEA-WAY consists of six Work Packages (WPs) and main objective of WP4 is assessment of the Adriatic port system and its integration with hinterland.
The EA SEA WAY project is a part of the IPA Adriatic Cross Border Cooperation Programme 2007-2013 co-financed by the European Union. The general objective of the project was to improve the accessibility and the mobility of passengers across the Adriatic area and its hinterland, through the development of new cross - border, sustainable and integrated transport services and the improvement of physical infrastructures related to those services.
The project was divided into 6 work packages which have involved:

- 20 partners,
- 16 associates,
- 8 countries (Adriatic-Ionian region).

2.2. Assessment of the passengers traffic flows in the Adriatic-Ionian area

The fourth work package (WP4) foresees the assessment of the Adriatic port system and its integration with hinterland, based on data collected on the applicable legal acts, studies, analyses and implemented projects (WP4, 2015). The study performed within the WP4 covered twenty ports in six countries of the Adriatic-Ionian region.

Fig. 1.
Adriatic-Ionian ports as a scope og WP4 research

The Adriatic–Ionian region in 2013 the region recorded approximately 5.2 million passengers and 17 million of cruise and ferry passengers, respectively (Čokorilo et al., 2015). The Fig.2 presents the current situation of Adriatic-Ionian port system integration with hinterland regarding the different modes of transport infrastructure.

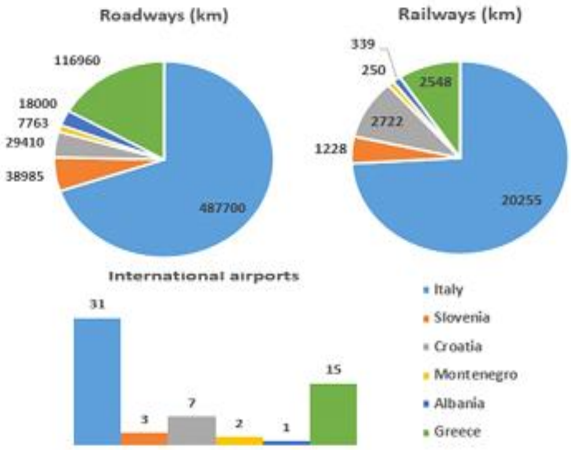

Fig. 2.
Adriatic-Ionian port system integration with hinterland

There was a significant gap in the density and degree of development of inland infrastructure in the countries of the Adriatic – Ionian region. In particular, the poor state of infrastructure, and hence the low quality of transport services, is characteristic for the Western Balkans countries.
Ports cannot expect significant progress in the future without good hinterland infrastructure. Rail and air transport represents a great opportunity for the seaport competitiveness and can considerably improve mobility within ports and their hinterland area.

3. EA SEA WAY Database

3.1. EA SEA-WAY Database functionalities

Development of database was one of challenges in order to do analyse of passengers behaviour and maritime traffic flows in the Adriatic basin. Developed database had great role to create scenarios linked to the development of: passenger traffic, transport modal choices, physical infrastructures and services.
Database is a software structure intended for storing, analyzing and searching a group of related and associated data. The easiest and fastest way of developing EA SEA-WAY database was to use Microsoft Access while this DBMS (Database Management System) allows to create user friendly interface through different forms for inserting and searching data as well as different reports for a comprehensive view of data. Microsoft Access enables easier database design, implementation, management and use. Microsoft Access 2016 provides a rich platform for developing database management solutions with easy-to-use customization tools (Microsoft, 2016). Also, due to some other technical features and benefits it was used this DBMS and version 2007 was selected due the widespread usage of this version. Developed database is desktop based version that allows flexibility for each user to perform the necessary changes and adapts to the database to specific needs.
EA SEA-WAY database provide the following basic functions:

- Data sorting in the corresponding tables and the corresponding data types,

- Creating a user friendly interface for easy manipulation of data,
- Enabled different reports that allow review of the data in summary form,
- Enabled to search data according to different criteria,
- Enabled options for printing data directly from the database,
- Enabled to converting reports in different formats, for example *.pdf.

EA SEA-WAY database facilitate development of studies and assessment of integration of the Adriatic port system with the hinterland**.** That could help improvement of Adriatic port system, its integration with hinterland and strengthening of intra-Adriatic connections.

3.2. Database model

EA SEA-WAY database consists many different data types. Many experts from different expertise fields included in making concept of database (Database Software and Applications 2016). Database consists indicators on passengers' behaviour and maritime traffic flows in Adriatic basin, current traffic volumes related to existing infrastructure and services, as well as to identify the weakness and bottle-necks in the Adriatic port system. This assessment should enable the creation of sustainable basis for traffic modelling. There are data for assessment of current and potential integration of Adriatic port system with hinterland, regional/local airports, rail network and main tourist destinations. There are some data that helps assessment of regulations related to passenger traffic and assessment of the scenarios linked to the development of: passenger traffic, modal choices, infrastructures and assessment of infrastructure development plans and its impact on traffic flows. Alternatively, the assessment should be adjusted to a finally accepted traffic model for the evaluation. According to these facts database covers several areas (sections) of data as follows:

- Port general information,
- Passengers port maritime traffic,
- Passengers' area and comfort facilities,
- Multimodal connections,
- Environmental issues,
- Demographic and socioeconomic data,
- Data for transport network,
- Data for generalized cost,
- Transport data,
- Infrastructure construction plan,
- Expected traffic flows after infrastructure investments,
- Swot analysis (for ports).

Data modelling helps to facilitate interaction among the database developer and the end user. It was made the relational database model and through the precise determination of the data types there are aligned data types to avoid inconsistency. Part of relations model is shown in Figure 1.

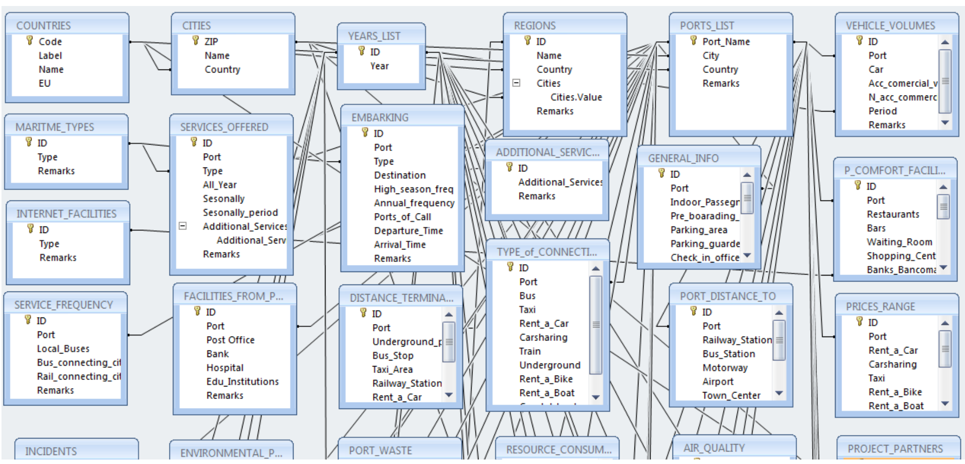

Fig. 3.
Part of Database Relations model

As we can see the relational data model is very sophisticated but DBMS hide the complexities of the relational model from the user and the user sees the database as a collection of tables that can manipulate and query the data. By using DBMS an user friendly interface was designed, customized and developed to allow the end user to interact with the data on easy way.

3.3. Database interface and reports

Due the huge number of collected data users should have user friendly interface with easy navigation through database sections. Microsoft Access forms (Microsoft Access 2016 Runtime, 2016) enable to display records in nice layout that will give users the comfort in controlling data processing tasks and user-friendly environment make EA SEA-WAY database easy to use . Database dashboard is shown on Figure 2.

Fig. 4.
User Friendly Interface (dashboard)

All data are stored in sections according to project objectives and experts who use this database can easly search data and find needed information. Dashboard consists “tabs” for quick access to all data and “Worksheets info” tab give a navigation and section description.

Fig. 5.
EA SEA-WAY database worksheets

To access data there are user friendly forms that opens when choose some worksheet. For example, worksheet 4.1.2 (Passenger Port Maritime Traffic) look like on Figure 4.

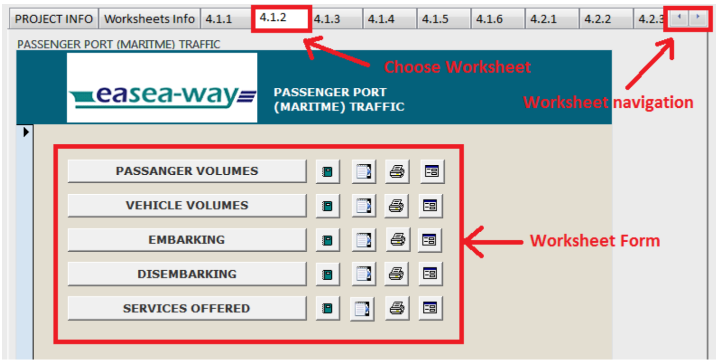

Fig. 6.
Part of Shortcuts Form

Microsoft Access enable users to can take a peek at additional relevant information in the database without changing screens, so they have the right context when reviewing or entering information (Microsoft Access 2016 Runtime 2016). In figure below it is shown one form for inserting and editing data. Forms enable to search data, insert new and edit existing data.

Fig. 7.
Form example for inserting and editing data

Another useful feature of this database are reports that enable the presentation of data. The final appearance of reports adopted to the needs and requirements of the users. Users of database can easily print and export reports in different formats directly from database. By using this database the user can create fully functional reports and can customize it by choosing among many options of style features. Example of database report is shown in figure 6.

Reports in Access can be easily created and that save time for more useful tasks.

4. Database beneficiary and usage

Database stakeholders includes: Project Leader and other Partners (FBs), Ports Adriatic-Ionian Area, Ministries and Regulatory Agencies, Project Manager, Project Office Manager, Project Review Group, Project Teams, Project Team members, etc. Database beneficiary includes (Europe - Adriatic SEA-WAY, 2016):

- Users will be able to get the relevant and systematized information
- Quick search of information required for project activities,
- Access to various statistical data relevant to the project,
- Search for the information needed for a particular analysis on one place,
- View of differences in the relevance of the data for individual ports and regions,
- Users will have access to data gaps in certain ports,
- Reports made in Access Database provide end user with an effective analysing and presentation of data,
- Useful data for further similar research.

EA SEA-WAY database is collection of information that helps in research and project deliverables of different studies such as:

- Assessment of passengers behaviours and maritime traffic flows, traffic volumes & infrastructures and services,
- Assessment of integration of Adriatic port system with hinterland, airports, rail network and main tourist destinations,
- Assessment of the legal framework related to maritime passenger traffic and harmonization proposals in the partner countries,
- Report of common needs and priorities identified related to passenger maritime transport and its integration,
- Report on scenarios and investment needs linked to the development of passenger traffic, modal choices and infrastructures,
- Guidelines for more sustainable passenger mobility.

Developed database could be used in similar projects and by all interested stakeholders while it is available on EA SEA-WAY project web site.

5. Conclusion

EA SEA-WAY database was developed to enable comprehensive view of data that are necessary for project activities as well as the need for storing data on one place and simply manipulation of them. Database has been developed with the aim to have a use-value not only to the EA SEA-WAY project but it can be used in other studies and similar projects that need data related to the Adriatic port system and its integration with hinterland. Database allow subsequent modification, upgrade and customization for future needs.

VISUALIZATION TOOLS IN SUPPORT OF ROAD ASSET MANAGEMENT

Salvatore Cafiso[1], Sławorir Heller[2], Giuseppina Pappalardo[3], Fabrizia Trovato[4]
[1,3,4] *Department of Civil Engineering and Architecture, Via S. Sofia 64, 95123, Catania, Italy*
[2] *Heller Ingenieurgesellschaft mbH, Otto-Hesse-Straße 19/T9, 64283, Darmstadt, Germany*

Abstract: Managing data of the Asset, such as inventory of geometric features, road sides, signs and markings, road structure data, pavement condition data, traffic volume, accident data, is one of the main issue of a transportation agency in order to apply an effective road asset management. In this framework, road agencies are increasingly reliant on rapidly growing data resources to provide the bases for making critical decisions about how best to allocate available resources to build, operate, and maintain safe, efficient, and sustainable road network. Technologies for collecting data have advanced dramatically, potentially enhancing the availability, accuracy and reliability of data while increasing demands on agency to ensure that their data can be effectively used.
In order to achieve the above goal, road agency at first needs to have software and visualization tools properly developed and applied. The combined use of GIS technologies and innovating software to create strip maps, can be helpful to show, compare and combine inventory and condition data within a strategic process. On the one hand, GIS technologies enable the management, analysis, and display of geographically referenced information at network level, on the other hand strip maps can present several groups of object data which are very important to the decision making process. The paper reports a set of successful "state-of-practice" of maps and strip maps for visualization road asset and pavement condition data and the use of high speed system to provide the condition of infrastructure by a safe, accurate, reliable and cost effective understanding.

Keywords: visualization tools, maps, road asset management.

1. Introduction

Road agencies are responsible for maintaining and improving physical assets to ensure safe, efficient, and reliable travel to the road users. As a result, one of the main functions of a transportation agency is collecting and managing data of the asset, such as inventory of geometric features, road sides, signs and markings, road structure data, pavement condition data, traffic volume, accident data. It is in order to apply a road asset management plan.
In recent years, there has been a substantial increase in both the performance and efficiency of the procedures for collecting data about road infrastructure. On the one hand, the information density as well as the accuracy of individual data are constantly increasing. On the other hand, the costs for data collection and evaluation are drastically decreasing.
Consequently, a rapid rise of databases has been recorded. The sole storage of data in databases and other files is by far not sufficient to support decision making processes. The available data must be provided in such a manner so that decision makers are able to integrate the data efficiently.
The visualization of road data is one of the most important forms of data provision. Appropriate visualizations (by using GIS technology and smart visualization tools) provide support during all phases and levels of the decision making process, i.e. from the operational and the strategic level through to the political level.
This paper presents a set of successful "state-of-practice" of maps and strip maps for visualization road asset and pavement condition data and the use of high speed system to provide the condition of infrastructure by a safe, accurate, reliable and cost effective understanding.
It is divided into three main sections:

- Background information on GIS in road asset management;
- Use of high speed system and Big Data to collect data of asset;
- Innovative data visualization tools to create graphical reports.

2. Background information on GIS for RAM

A geographic information system or GIS helps to store, manage, analyze, manipulate and display data (i.e. road inventory data) that are linked spatially. GIS relates database records and their associated attribute to a physical location, thereby creating a "smart map". Visualization of discrete parts of these data on a GIS map and spatial analysis are possible by layering the data into different "themes". GIS applications can then display the intersection of various "themes", as well as the spatial relationships between various features.
GIS enables integration of disparate data entities using location as the common denominator, visualization of multiple data layers for a selected area or network location, map-based data access for viewing and editing, and spatial analysis involving queries of information based on proximity, route, or geospatial feature. In addition, GIS technology (including global positioning systems or GPS) provides a cost-effective means of collecting geospatially-referenced data in the field of inventory, inspection, and work recording. It also allows the innovative "crowd-sourcing" approaches in which citizens can report locations of asset deficiencies via mobile devices or desktop tools.
As reported in NCHRP Report 800[2] the use of GIS is yielding a variety of improvements in asset inventory control and maintenance management, condition assessment and monitoring, database management. It also helps transportation agencies to manage and carry out Transportation Asset Management.

[1] Corresponding author: dcafiso@dica.unict.it
[2] NCHRP Report 800 *"Successful Practices in GIS-Based Asset Management"*

Transportation Asset Management or TAM is a strategic and systematic process of operating, maintaining, upgrading, and expanding physical assets effectively throughout their lifecycle. It focuses on business and engineering practices for resource allocation and utilization, and the aim is a better decision making based upon quality information and well defined objective. There are five core asset management processes: identifying the state of the assets, assessing and managing risk, identifying needs and work candidates, developing programs and managing and tracking work.
In this framework, the use of GIS by transportation agency provides three essential ingredients that enable agencies to effectively carry out TAM processes. These are information integration, analysis, and communication; Figure 1 illustrates how they can be applied within an asset management context.
Asset management is by nature data driven and GIS capabilities help agencies to understand what they own, what their needs are, and the best process to apply available resources to meet these needs in a holistic manner.

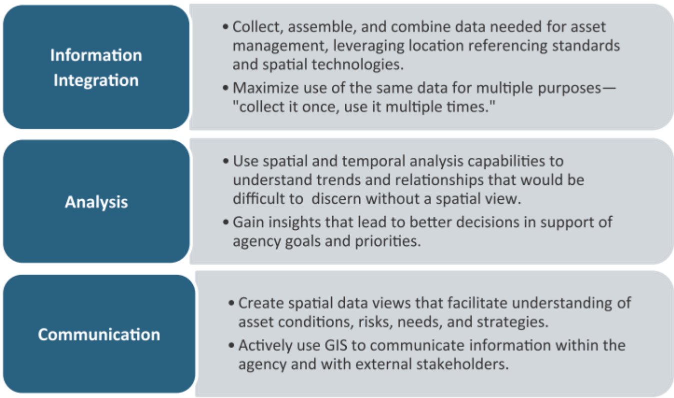

Fig. 1.
GIS capabilities for transportation asset management
Source: (NCHRP) REPORT 800 "Successful Practices in GIS-Based Asset Management".

In order to implement TAM, there is no single way to utilize GIS. However, it is useful to distinguish different levels of implementation in recognition, there are some "basic" capabilities that need to be in place before an agency can move on to more advanced applications.
In general, basic capabilities involve using GIS to visualize some information, such as asset location and condition for pavement and bridge management. Advanced capabilities involve the use of spatial data integration and analysis, specialized GIS enabled applications that support workflow, and more formalized and automated processes for creating, using, and sharing geospatial data across business units.
There are four business process for transportation agency. The first business process for transportation agency is to understand the state of the assets and it is perhaps the most common basic area within which GIS is currently being used. In fact, agencies collect spatially-referenced asset inventory and condition data using various technologies and they use GIS capabilities for inspection planning, data quality assurance, and data display. As soon as the data collection is completed, transportation agencies go into more advanced capabilities of GIS, such as standardized and consolidated data collection efforts across assets, leveraging additional GIS capabilities for data quality assurance and inspection routing optimization, standardizing and automating processes for communicating information about the state of the assets. The second asset management business process involves the understanding of various asset failure mechanisms, assessing their likelihood and consequences, and developing mitigation strategies.
The third asset management business process involves the developing asset maintenance, rehabilitation, replacement, and improvement strategies that address risks and optimize life-cycle costs. Finally, the last asset management business process involves scheduling, delivering, and tracking maintenance and construction work.
In all the business processes transportation agency use both basic and advanced capabilities of GIS, in order to integrate additional data, utilize spatial analysis capabilities for calculating risk scores and involve real-time applications for asset monitoring.
As mentioned above, it is clear that GIS, as a professional software, can help agencies to apply a rational and efficient approach to asset management. However, while some of them have made substantial progress in using GIS for asset management, many challenges still remain related to the development of complete, quality geospatial data, standardization and synchronization of location referencing information across individual asset and maintenance management systems, implementation of data governance structures and processes, and automating spatial data integration and analysis tasks.
In order to face up to some of these challenges, it is important to define some standards starting from the phase of asset data collection. Nowadays, the substantial increase in both the performance and efficiency of the procedures for collecting data regarding road infrastructure has become evident. On the one hand, the information density as well as the accuracy of individual data are constantly increasing. New high speed systems, such as Automatic Road Analyzer, have been developed in order to meet the rigorous data collection requirements of the road infrastructure. On the other

hand, the costs for data collection and evaluation is decreasing drastically due to the introduction of new ways of collecting, managing and analyzing vast quantities of data (big data) collected from and about transport.
The above arguments will be discussed in the following paragraph.

3. Use of high speed system and Big Data to collect data of asset

Data collection and processing are an important and difficult phase in road asset management. It should be performed with specific device or should be carried out as a result of a careful review of open data that are enabling the use of big data in transport asset management.
Different types of data are required for managing transportation infrastructure. Data collection technologies and data needs vary depending on the type of infrastructure element which is evaluated. In general, there are three main types of asset management data

- Inventory data: data that describe the physical element of the road system and road assets and are mostly static in nature;
- Road structure: data that contain information about bridges, tunnels and retaining walls;
- Condition data: data that can describe the condition of assets and these data changes over time.

Typically, road data are collected by technologies and equipments that should guarantee reliability, efficiency and ability of the system to secure the data collected. It will be advantageous if the equipment or methods employed in data collection can collect road data in a single operation so that the collection will be cost-effective and consistent in referencing. Moreover, in order to carry out transportation asset management, it is important to collect other data such as traffic volume, accident data and weather data that can be available in road agencies archives or as open and free data.

3.1. Automatic Road Analyzer

Automatic Road Analyzed 9000 (Fig. 2), a high speed system with a productivity of 200km/die that allow to collect more than fifteen different data streams continuously and at varying capture rates in a single pass at traffic speed.

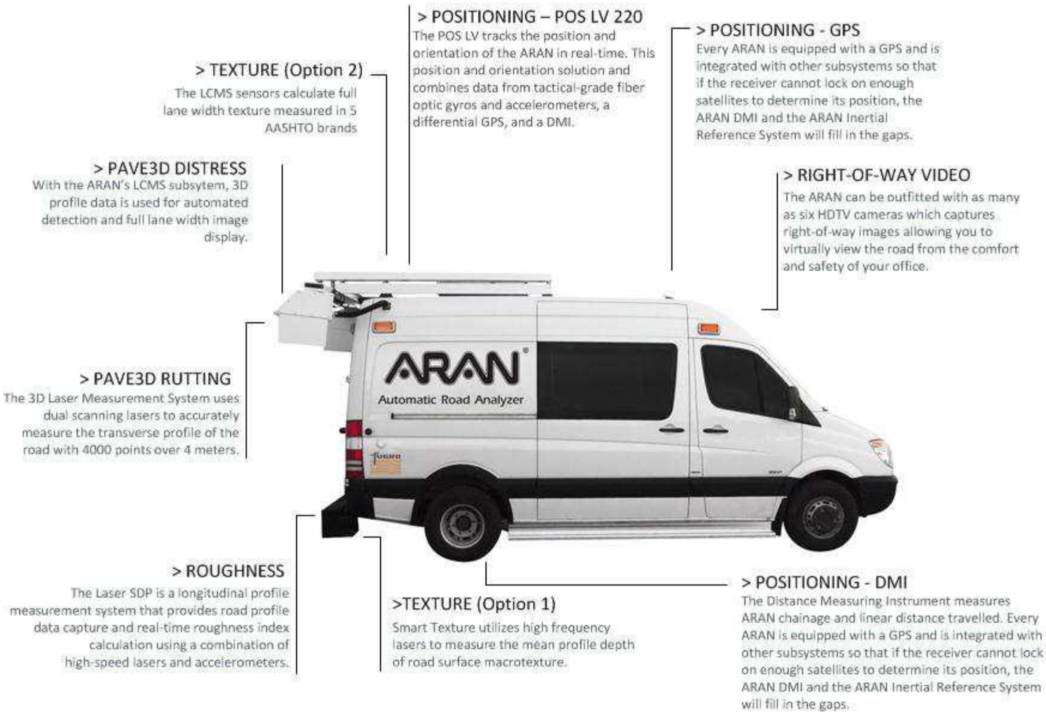

Fig. 2.
Automatic Road Analyzer 9000

ARAN 9000 has recently been acquired by the University of Catania that is currying out an extensive research program for system calibration and output adaptation to a performance based inventory of the road infrastructures.
The ARAN, fully integrated into a high roof chassis, is an advanced pavement data collection vehicle equipped with precision survey system and software able to perform the collection of road's geometric data (cross section, gradients, horizontal and vertical alignment), pavement unevenness, detection and classification of distress and road asset inventory data. It also takes care of the acquisition and filing of the images of accessory elements (for signals, advertising, rights of way, etc.).

All the data returned are accurately located using any geographical reference system (e.g. Gauss-Boaga or UTM) with the help of a satellite differential correction receiver (DGPS), coupled with an inertial platform and they are associated with chainages coming from odometer (DMI), as well.
The pavement detection is carried out by a system which collects continuous 3D images of all type of road surface. The system is composed by Laser Crack Measurement System (LCMS), SmartTexture and SDP Lasers. LCMS is a high speed and high resolution transverse profiling system capable of acquiring full 4m width 3D profiles of a highway lane at normal traffic speed. SmartTexture is a laser that measures the macro texture of the road at speeds of up to 90 kmph. SDP consists of lasers and accelerometer, coupled and installed under the respected wheels paths. The system complies with the ASTM E950-09 standard for the detection of longitudinal profile and International Roughness Index (IRI) post-calculation.
Because of the high rate of acquisition from the LCMS, automatic cracking detection, macro-texture evaluation and rutting measurements are possible. The collected raw 3D pavement data from the LCMS hardware is then derived to more useful information such as texture, cracks and distresses, lane width, transverse profile and rut. The detected cracks are analyzed using a dedicated software (Fig.3) that includes pattern recognition algorithms to determinate the types of distress. Cracking data can then be reported by roadzone, severity level and by aggregating the data to determine length of cracking, width, number of cracks, area of cracking and extent (length of road affected).

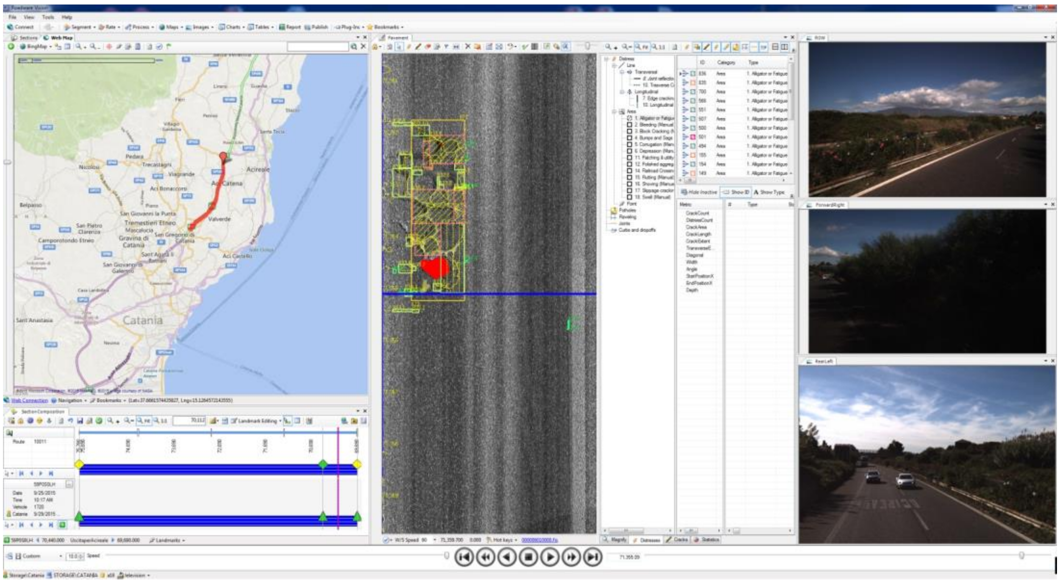

Fig. 3.
Vision software user interface

The automatic crack detection and classification (Fig.4) was calibrated on field data and adapted to provide useful information for post elaboration of performance indices able to characterize the pavement serviceability and maintenance needs (e.g. PSI, PCI). Figure 4 shows improvement in the detection and clustering of different defects after calibration (e.g. density=1.8) from the default values (e.g. density 1.2)

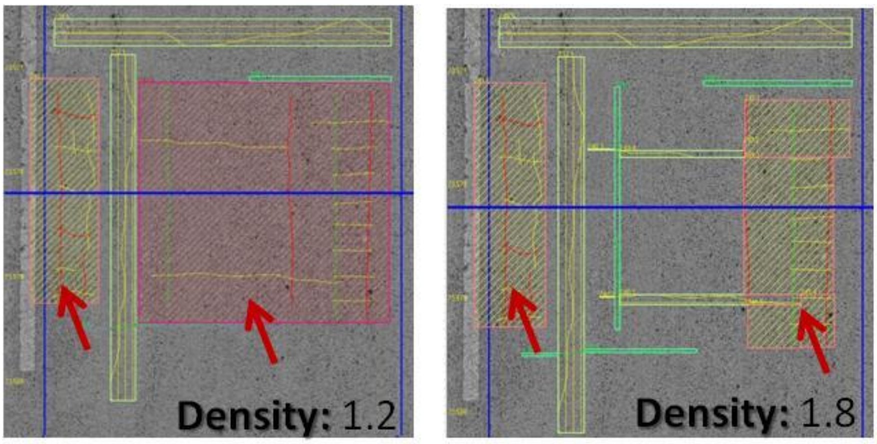

Fig. 4.
Automatic crack detection with density analysis

The asset inventory detection is carried out by using the ARAN surveying vehicle in combination with the HD Videolog system and the Surveyor asset extraction software. The high quality of the two front cameras and one rear

cameras with a resolution of 2750x2200 pixel, ensuring a complete detection of road environment in a field of view of 240°. The Videolog and GPS systems work in sync to provide the geo-referencing of digital images; moreover, the inertial aided navigation system ensures that GPS accuracy is maintained even during long satellite blackouts with sub-meter precision.
The images analysis for extracting road inventory assets is carried out by using a software tool that allows to displays, measures and inventories any road features located along the road and displayed in the image (e.g. lane, shoulder width, sign, marking, roadside, safety barriers, …). More specifically, after calibration of the camera system, it is possible to locate and measure the main dimensions (length, height) of any object along the roadway. Figure 4 reports an example of carriageway measurement and the collection of additional information about pavement and barriers.
A compressive asset inventory was defined able to include not only the base information required by the national guideline for road cadaster (D.M. 2001) but more data needed for checking the compliance with design standards (e.g. geometric design, safety barriers, signs and markings) and finally to estimate the safety performance of the network.

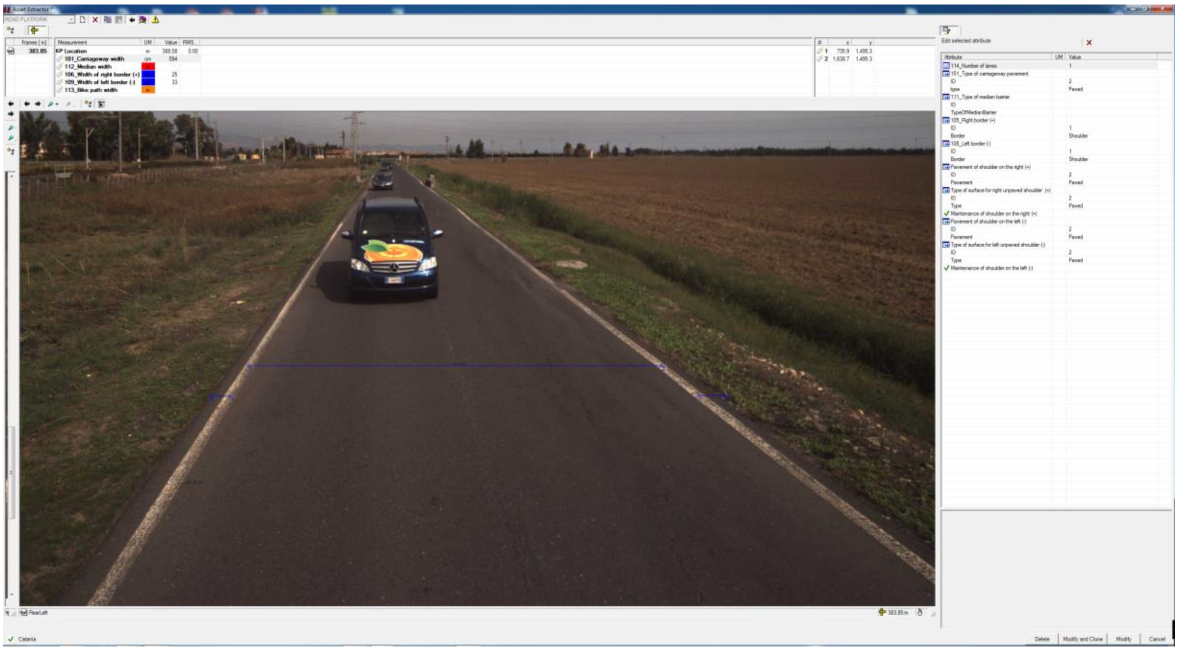

Fig. 4.
Surveyor software user interface

After the HD images have been analyzed all the asset recorded can be extracted as a database file and imported into any GIS tool for the Asset Management System (AMS).

3.2. Big Data

Big data consist of data on a scale or of a complexity that makes it challenging to use. The main features of the scale and complexity of 'big data' include the 3V features:

- high volume – large quantities of data that can range from terabytes up to petabytes in size,
- high velocity – data that must be collected and analyzed rapidly to be useful
- high variety – data consisting of many different forms, often brought together from varying sources

The transport sector has always collected and analyzed large quantities of data, such as data from timetables, traffic news and air schedules. However, recent developments in the quantity, complexity and availability of data ('big data') collected from and about transport, together with advances in computing technology, are presenting new opportunities and challenges to create more efficient and smarter transport systems for people and freight. Using big data can increase efficiency and can reduce the costs to infrastructure and service operators, and can provide better levels of services to users in asset management. Big data offer new opportunities to identify problems more quickly and to reduce costs. Already applications exit where smartphones have been used to crowd-source information about the state of road assets and this information was used to provide insights into traffic conditions on local road networks. These applications provide real time data and can be used to fill the lack of fixed sensors. Transport data are also likely to be further integrated with data from other sectors and an increasing variety and volume of user-generated content. This may enable more efficient and sustainable transport networks as well as more efficient road asset management in the future.
In this framework, it is possible to introduce the project idea of WIKI Roads Map, startup project of the University of Catania, founded by Ministry of Educational: the creation of a collaborative system that uses an organic and innovative data stream originating from road infrastructure and the surrounding area by applying semantic analysis technology for the extraction, collection, integration and publication of data to allow users, both public and private, the acquisition of a greater knowledge, an analysis of the issues relating directly and indirectly connected to it.

4. Innovative data visualization tools to create graphical reports

The data acquired by using high speed systems and collected as big data need to be managed in order to became useful in a road asset management process. The sole storage of data in databases and other files is by far not sufficient to support decision making processes. The available data must be provided in such a manner that decision makers are able to integrate the data efficiently and specifically in their decision making process. The visualization of road data is one of the most important forms of data provision. Appropriate visualizations provide support during all phases and levels of the decision making process, i.e. from the operational and the strategic level through to the political level.

In most management tools, roads are represented as space objects that are visualized primarily on maps along with their attributes by using a set of coordinates. Unlike the spatial representation, the method of linear referencing is easy to understand, does not require sophisticated technology and it allows the user to reference locations in the field using physical markers and identifiers. The progressive standardization and unification of management software in the last years have led to uniform visualizations for all space objects. However, such a universal "GIS-approach" limits the number of possibilities to visualize road specific features in a way that the needs of road professionals can still be taken into account optimally. In fact, GIS visualization can present just a limited groups of data by layering and it serves well to present data and decision results at network level. During both the planning phase as well as the maintenance phase, the road is usually considered as a linear object in the space. Therefore, the localization of all road events and attributes mainly takes place in relation to the road axis, and not by means of geographic coordinates. Information such as traffic load, areas with speed limits, administrative areas, accident sites or road construction is always described in relation to the road, i.e. with help of road millage. Thus, it becomes possible to combine data of a different nature and therefore gain more complex findings relevant for the management. In modern systems, focused on the support of the Transportation Asset Management, roads are represented as linear objects (Fig. 5).

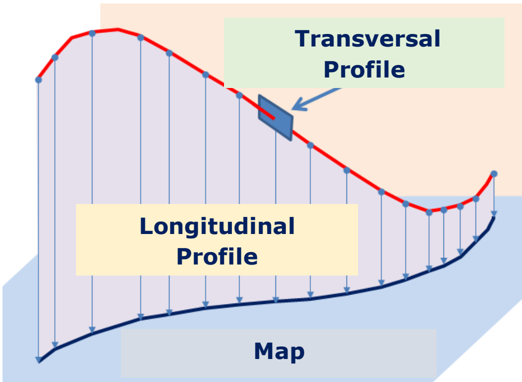

Fig. 5.
Road as a linear object with the three most important perspectives

Therefore, the visualization of the attributes takes the following three perspectives into account: map (Fig.6), cross section (Fig.7) and profile (Fig. 8).

Fig. 6.
Example of a thematic map with condition data of road surface

Thematic maps of road surface condition are the most commonly used graphical reports in Pavement Management Systems. In Fig.6, pavement condition is indicated by four different colors. This provides a very good overview and uses a display technology that presents the condition of all lines on one plot.

In Fig. 7 a strip map with cross-section and surface construction is shown. For planning and management issues, the actual extension of the road usually is irrelevant. Therefore, all presentations operate with several distorted geometric objects in order to focus the attention on what is essential and to supply the information in the desired combination.

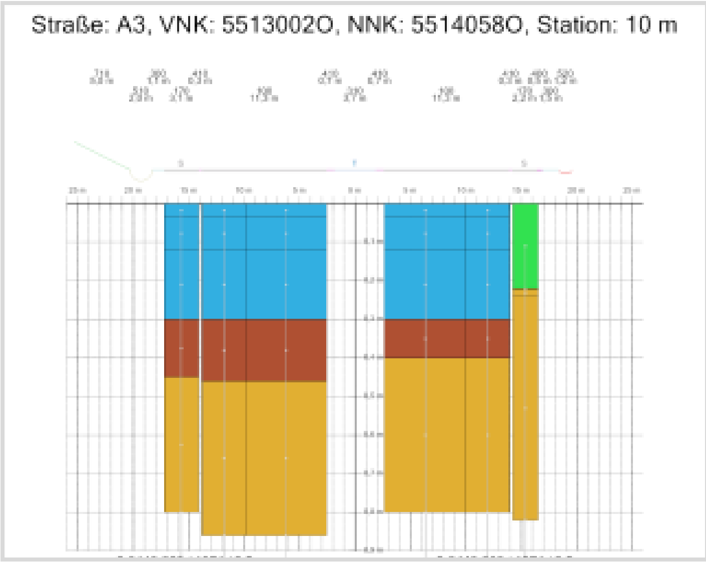

Fig. 7.
Example of a cross section

Fig.8 is an example of strip maps that presents many groups of data within one road section. Such strip maps are useful for the visualization of elementary data (e.g. pavement surface condition). For PMS purposes, road agency need a profile that can show a condition data of short road sections is aggregated to longer sections, as in the profile below.

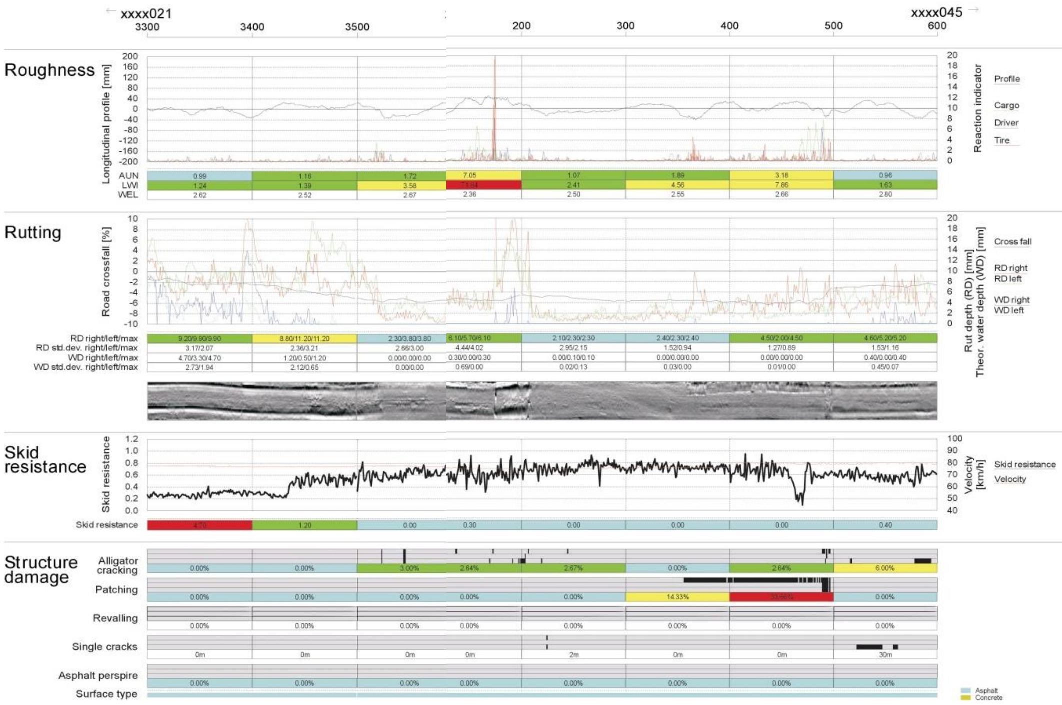

Fig. 8.
Example of a profile with condition data (right side)

It is of great importance that all visualizations correspond with their respective applications at all times. The systems creating the graphics need to be flexible in order to enable adaptations to the users' needs. Furthermore, it is also important to offer an interactive screening of the relevant data in all dimensions. Such visualizations, that are often provided as online services, enable a “virtual ride” through the road network. All elements of visualization, i.e. the map, the profile and the cross section, are being constantly synchronized (Fig. 9).

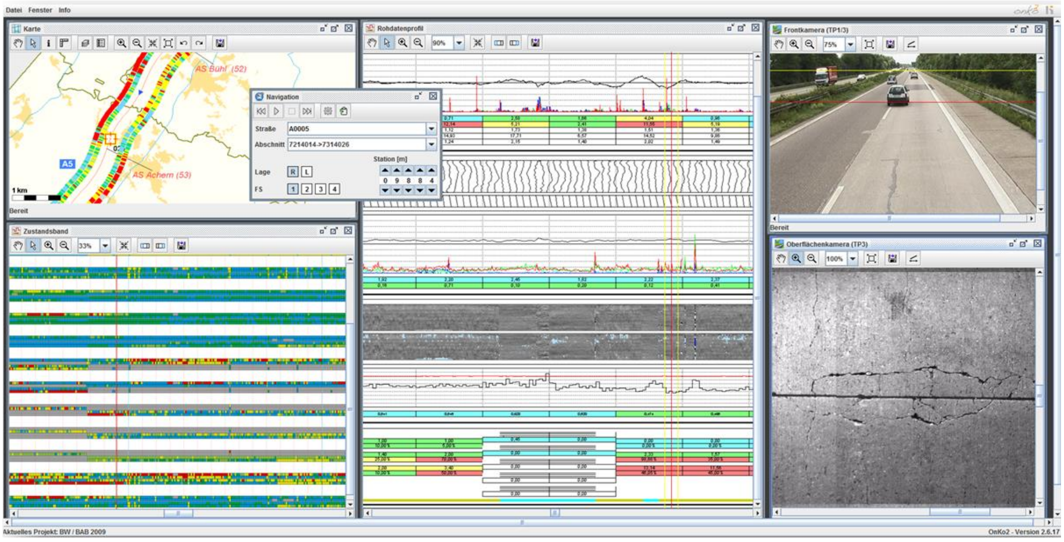

Fig. 9.
Interactive and synchronized representation of road information provided online for the operational level

5. Conclusion

The paper has highlighted present and future opportunities for enhancing the data collection and acquisition from different sources. Apart of the potentialities offered by the new technologies in terms of data quality (high speed collection systems), volume, variability and velocity (Big Data), there is a need to transform data into information useful for Road Asset Management. Appropriate algorithms have to be developed to combine data coming from different sources and visualization tools have to be provided to the decision makers.
A wide range of opportunities for leveraging visualization tools in support of road asset management have been proposed.

- Visualization tools can help road agency in the communication with customers, stakeholders, and decision makers.
- Visualization tools can be used to show the data collected by using high speed system to support an effective Pavement Management program.
- Innovative data visualization tools allow to show a wide group of data such in only one plot, in simple and understandable way.

Acknowledgements

The ARAN was acquired in the context of the RESET Project, founded by Sicilian Region Authority to strength regional research laboratories. The research was founded by WIKI RoadS Map, national start up project founded by Ministry of Educational.

[1,2,3,4,5] *University of Belgrade Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, Belgrade, Serbia*

Abstract: Failure to comply with speed limits and speeding belong to the most common unsafe behaviors of traffic participants. Therefore, the speed control represents one of the most effective mechanisms for raising the level of road traffic safety. The velocity analysis must come before the process of road speed control. Nowadays, most of the data on vehicle speeds on public roads in the Republic of Serbia is received from the automatic traffic counters (ATC). If we want to analyze the speeds obtained from 391 counters in the Republic of Serbia, on an annual basis, it is necessary to process over one billion records. This paper proposes an original model of processing data on vehicle speeds that are received using the ATC, in the Big Data technological environment. Big Data technology was developed with the aim to enable an efficient processing of massive quantities of heterogeneous data that arrive faster than the speed of processing, and cannot be handled with the help of conventional tools. The proposed model has been tested on the Apache™ Hadoop® Big Data platform by analyzing vehicle speeds that have been registered by ten traffic counters, positioned in the city of Novi Sad and its surroundings during the year 2015. The indicators were calculated for each counting place using HiveQL query language and Hadoop platform's service, in total and for each direction, annually, as follows: average vehicle speed, vehicle speed standard deviation, median and mode vehicle speed, maximum and minimum vehicle speed, 85. percentile of vehicle speed, distribution of the number of vehicles per speed categories, the number of occurrences of each registered speed at the counting site, percentage of distribution of vehicles by the levels of speeding - for all vehicles or particular category, etc. All calculated parameters were presented graphically and geo-referenced using modern business intelligence tools. Testing has shown that Big Data technology enables more efficient data processing of vehicle speeds compared to the conventional software tools.

Keywords: big data, automatic traffic counters, analysis of vehicle speed, data visualization.

1. Introduction

Observation of road traffic includes the following activities: vehicles detection, traffic counting, length and/or speed measurements, vehicles categorization, etc. Speed management has the task to provide conditions for efficient, cost-effective and safe modern traffic (Subotić et al., 2014). Vehicle speed detection involves the use of various sensors, which almost continuously generate data. The highly developed detection technologies can be classified into three categories: in-roadway detectors, over-roadway detectors, and off-roadway technologies (Martin et al., 2003). In the current play of events, transportation industry cannot meet the rapid growth of data. Also, the traditional data processing systems are becoming inefficient with sporadical failures. On the necessity of solving the problem of processing large amounts of data in transport speak director of Analytics for Urban Insights in the following way: "One of the biggest challenges facing the global transportation industry today is the massive amounts of rich data being gathered but underutilized by urban transportation enterprises" (Rosado, 2014). Traffic engineers accepted the Big Data analytics when they understand that scientific data processing can replace costly projects of construction or reconstruction of roads (Leopold, 2014). Big Data refers to information resource in terms of volume of data, the variety of formats and speed of arrival, that exceeds the possibilities of traditional database management systems (DBMS) (Janković et al., 2016). Currently, the most widely used data sources in traffic are traffic surveillance systems (Shi et al., 2015). Big Data systems are suitable for monitoring the system behaviour, collecting and analyzing defects. These systems offer monitoring of the whole system and its operation in detail which was previously impossible. Intelligent Transportation Systems (ITS) use Big Data with the aim to increase energy efficiency, improve traffic safety, reduce air pollution, relieve traffic congestion, and improve homeland security (Ni, 2015). The advantages of Big Data concepts are improving the safety of traffic and the efficiency of the transportation industry in general (Zeng, 2015).
We have recognized the sensory data, which is widely used in traffic, as a category of data that makes sense to cultivate using the Big Data technologies. Therefore, in this paper we propose a methodology for managing sensor traffic data by using Big Data tools. The methodology includes models of storage, as well as processing, analysis and visualization of data on speeds on the roads in the Republic of Serbia, which are collected by automatic traffic counters. All proposed models are based on the use of Apache™ Hadoop® Big Data tools. Our research includes vehicle speed analysis from nine selected locations on the roads in Novi Sad and its surroundings in 2015. Realized case study showed that Big Data tools are more efficient in managing and processing of sensor data compared to traditional DBMS. Also, it was found that Big Data tools have a feature for simple import or export data to the traditional DBMS.

2. Speed Detection Technologies

Vehicle speed detection is very important for traffic monitoring and it also demonstrates traffic condition. There are cases where the driver does not obey the traffic rules or the speed of the vehicles is beyond the road speed limit. The vehicle that moves faster from the defined speed limit is very dangerous and increases the chances for the accidents. In

[1] Corresponding author: s.jankovic@sf.bg.ac.rs

this section we will present the following speed detection technologies: speed measurement with wireless technologies, radar, laser, laser scanner, pressure sensors and multiple beams. These technologies are applied depending on the existing road infrastructure and environmental conditions.

2.1. Speed Measurement with Wireless Technologies

Intelligent transportation systems use this technology for traffic monitoring as well as to calculate the average speed of the vehicle. (Libelium, 2016). Libelium has launched platform for traffic monitoring which enables system integrators to create intelligent monitoring systems for the urban environment. Figure 1. shows traffic monitoring through waspmote devices. In this case a Bluetooth technology is used for communication of sensor device to make inquiries and detect nearby devices. The sensor data is transferred by a multi-hop ZigBee radio, via an internet gateway, to a server. Meshlium network device running on Linux operating system enables different radio interfaces such as: WiFi 2.4GHz, 5GHz WiFi, 3G / GPRS, Bluetooth. In order to detect a vehicle, WiFi or Bluetooth interface in the vehicle must be set to be visible. These systems can be used to calculate the average speed of vehicles passing between the two sites.

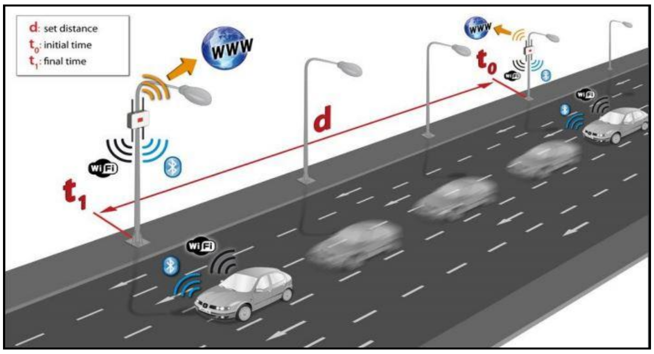

Fig. 1.
Traffic monitoring
Source: Libelium, 2016.

2.2. Speed Measurement using Radar

Radar in traffic is very often associated with speed enforcement system. In all radar devices, speed measurement is based on the Doppler effect. As we can see stationary autonomous speed measurement with radar is shown in Figure 2. The radar antenna transmits a narrow radar beam at a fixed angle to the orientation of the roadway. If a vehicle enters the radiation field from the antenna, part of the radiation is reflected and received back to the antenna. Due to the vehicle’s motion, the frequency of the radiation changes proportionally with the the speed of the vehicle. Therefore, based on the frequency difference between the transmitted and reflected radiation, the vehicle’s speed can be calculated.

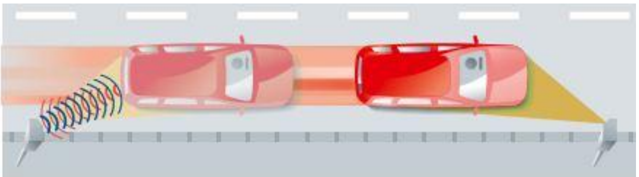

Fig. 2.
Stationary autonomous speed measurement with radar
Source: METAS, 2013.

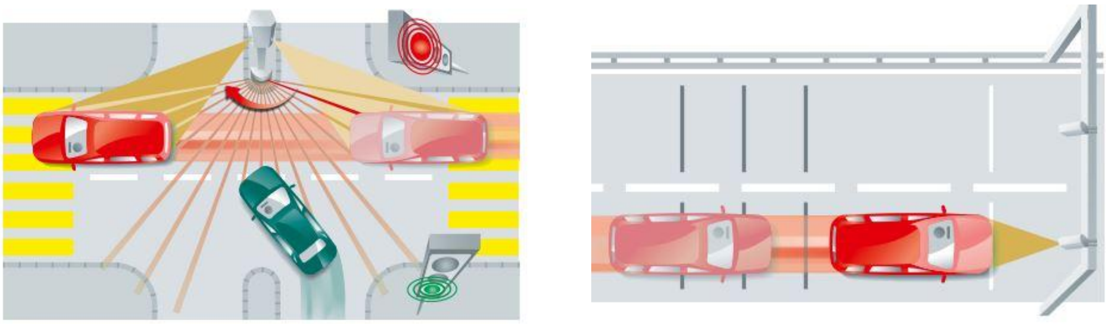
Another generally used technique involves speed measurements using radar device that is worked at a fixed location over a longer period of time. The measurement equipment either uses a fixed installation or it is housed in a transportable measuring booth. This system operates autonomously without any supervision. The recorded speeding violations are either saved locally or transmitted directly to an evaluation centre (METAS, 2013). The disadvantage of such measurement is the use of expensive digital signal processors and complex Fast Fourier Transform (FFT) techniques (Hagargund et al., 2013). This method of measurement is very suitable for speed measurements in intelligent traffic systems.

2.3. Speed Measurement using Laser

When measuring speed using laser, the delay between individual infrared pulses from the transmitter to the vehicle and back to the receiver is measured. Based on this delay, it is possible to compute the distance between the laser device and the vehicle. The distance travelled between two infrared pulses divided by the associated time interval is equal to the vehicle's speed. In theory, it would be possible to perform a speed measurement in this manner using only two laser infrared pulses. In practice, this results in errors, for instance, if the intended target point changes. In order to eliminate erroneous measurements, more series of delay measurements is performed and saved as a part of a measurement procedure. Using a mathematical operation, the vehicle's speed is finally computed from the measured values. The measurement data, date, time of the day and traffic situation at the time of measurement are recorded using analogue or digital image documentation systems (METAS, 2013).

2.4. Speed Measurement using Laser Scanner

Laser scanners have been used for a long time in different monitoring scenarios, for example, at industrial sites or in museums. They are able to detect and record events and trigger an alarm if necessary. Using appropriate evaluation software, it has become possible to measure speeds using laser scanners. This type of devices can be used to monitor a larger traffic area. It is possible to make all types of instant installations such as stationary, supervised, autonomous, fixed and. Laser scanners can also be combined with red light monitoring. Furthermore, they facilitate front and rear shots of the particular vehicle from a booth mounted on a mast. The application of laser scanner as a multifunctional system and speed measurement with pressure sensors are presented in Figure 3a).



a) b)

Fig. 3.
a) Laser scanner as a multifunctional system
b) Speed measurement with pressure sensors
Source: METAS, 2013.

2.5. Speed Measurement using Pressure Sensors

Measurement systems based on pressure-sensitive piezo-electric sensors are used exclusively for speed measurements on highways. In Figure 3b) it can be seen speed measurement with pressure sensors on two-lane highway. They are commonly combined with variable traffic sign controllers. These systems are often used on the road sections where different speed limits are applied in phases to control the flow of the traffic (METAS, 2013).

2.6. Speed Measurement using Multiple Beams

Wavetronix company has developed speed measurement based on the multiple beams. With the two beams generated by SmartSensor HD transmit parallel to each other, create speed trap similar to a dual loop system. This speed trap allows more accurate measurement compared to the radar traffic detectors. Algorithms measure the time it takes a vehicle to move from one beam to the other. This results in highly accurate speed measurements and more precise vehicle classifications (Wavetronix, 2016).

3. Methodology for Vehicle's Speed Data Processing

In this research, we have developed a methodology for processing data of vehicles speed on the roads in the Republic of Serbia, based on the use of Big Data tools. Our methodology includes methods for solving the following tasks: collecting data on vehicle speeds on roads in the Republic of Serbia, storing of collected data, processing the data in order to find useful information and analysis speeds on roads, graphical presentation and geolocation of data.

3.1. Data Collection

To create constructive conclusions about the speeds on the roads, it is necessary to include the speed of all vehicles that were moving on the observed section of the road for at least one year. Automatic traffic counters (ATC) based on inductive loops have an important role in the traffic monitoring. Currently, in the area of Serbia 391 ATC are used (Lipovac et al., 2015). While vehicle passes the induction loop, ATC generates numerous data including the vehicle speed. To count the traffic at the specified locations, among other, the counters type **QLTC-10C** were used (Microbit, 2009). These traffic counters were produced by Slovenian company Mikrobit. Each counter, during the course of the day, "writes" the data into a text file, so that during one year each counter generates 365/366 files. The name of the text file contains a date and the current year when traffic counting was performed. Txt file size is determined by the volume of the traffic in one day at the observed counting place. For each vehicle registered by a counter, one record is created in the text file. Record in the text file, contains the following information:

- Index: a daily number of the vehicles per traffic lane,
- Date and time: in the following format: dd.mm.yy hh:mm:ss,
- Channel: it may have the values from 0 to 3 depending on the order in which the vehicle encounters a loop,
- Lane: it can have values: 0 (a vehicle is in the lane marked as 1) or 1 (a vehicle is in the lane marked as 2),
- Vehicle class: vehicle category,
- Vehicle speed: expressed in km/h,
- Vehicle length: length without the correction factor, expressed in cm.

3.2. Data Storage

In order to store the huge traffic data, we have chosen the Big Data platform - Apache™ Hadoop®. Hadoop is an open-source framework used for storing and processing Big Data in a distributed environment (White, 2015). It contains two modules: MapReduce and Hadoop Distributed File System (HDFS). MapReduce is a parallel programming model for processing large amounts of structured, semi-structured, and unstructured data on large clusters of commodity hardware (Hayes, 2015). HDFS is a part of Hadoop framework, used to store and process the datasets. It provides a fault-tolerant file system to run on commodity hardware.

One of the substantial HDFS features is the ability to upload text files. We should recall the that the data generated by automatic traffic counters are kept exactly in the text files. Therefore, there is no explicit limitation related to the file size! Another important feature of Hadoop platform is that it allows the transfer of data from a text file to its database tables.

This feature can be used only if the data are structured in the text file. Since the data are stored in the text format, we suggest automatic upload of these files to the HDFS. However, for the purpose of analyzing vehicle speed during an entire year, each traffic counter should upload 365 or 366 of these files. It is obvious that this kind of storage is inefficient for large amounts of data. To solve this problem we have created a Windows application in MS Visual Studio 2015. The application provides saving all the data collected from one counter during a year in just one text file. After that, these large text files can be uploaded to the HDFS.

The next step is to create Apache Hive database which will easily import data from uploaded text files. Table in the database should be created for each text file that is uploaded to a HDFS. The table structure must be identical as the structure of the text file. Thereafter, it is necessary to create an Apache Hive query for each table with the command LOAD DATA INPATH. After MapReduce module executes a query, the data from selected text files is transferred to the specified table in the database. When all text files, uploaded to the HDFS, finish import to the Apache Hive database tables, the process of storing data at Big Data platform is completed.

3.3. Data Processing and Analysis

Apache Hive is a data warehouse infrastructure tool designed to process structured data in the Hadoop. It resides on the top of Hadoop to summarize Big Data, and makes querying and analyzing easy. The Hive is built into the “SQL like" query language Hive Query Language (HiveQL, HQL) which allows the manipulation of data in the Hadoop through queries that are almost identical to standard SQL queries. This tool is easy to integrate within the existing tools such as Microsoft Office Excel.

Processing and analyzing of data related to vehicle speeds implies writing and executing of numerous Apache Hive queries. The results of these quiries should include information that may be very useful for the traffic experts in performing an analysis of the speed on the roads. Some of these information are:

- Average speed of vehicles,
- Standard deviation of the vehicle speed,
- Coefficient of variation of vehicle speed,
- 85th percentile of vehicle speed,
- Percentage of vehicles that exceed speed limit,
- Percentage of vehicles that exceeded speed limit with more than 10 km/h,
- Average speeding, etc. (lipovac et al., 2014).

All listed indicators of traffic safety can be calculated for each category of the vehicle. ATC classifies each registered vehicle into one of 10 categories. Additionally, analysis of the aforementioned indicators could be used depending on the day of the week or time of the day.

3.4. Data Visualization

Analysis of vehicle speed means observing dozens of indicators at all measuring points on the roads. We must bear in mind that almost four hundred ATC is placed on the public roads across Serbia. For this reason, it is obvious that a tabular presentation of calculated indicators is not good enough, information would be more usefull if displayed on the road maps. In order to allow the visualization and geo-location of the query results, we propose to make available tables and views from Hadoop database in Microsoft Office Excel 2013. This can be usingMicrosoft Query Wizard. Analysis and graphical presentation of the data can be enabled with the help of Excel's add-ons, Power View and Power Map.

4. Analysis of Speeds on the Roads According to the Proposed Methodology

In the conducted research we have used data obtained from nine automatic traffic counters, that were set in Novi Sad and its surroundings. Presented data are the result of traffic counts during 2015, by automatic traffic counter type of QLTC-10C. Each of the nine counters had 365 files and each text file kept between 4000 and 14000 records. This led us to the following question: how to handle more than 30 million records and draw any useful information from such a large number of data? According to the methodology presented in section 3, we realized the following activities:

1. "Clean up" text files of counters from any invalid records,
2. For each counter, consolidate the content of all 365 text files into a single large text file,
3. Upload each one of the 9 text files into the hadoop big data platform hdfs,
4. Create a database *traffic* in the hadoop platform and use it to store data from the 9 uploaded txt files,
5. Create useful queries against a previously created database in the hadoop platform,
6. Make available the query results that are stored in a database on hadoop platform in a conventional environment for analysis and data visualization with microsoft office excel 2013,
7. Analyze the data and graphically present them in excel.

Activity 4: for each uploaded text file we generated one table in the *Traffic* database. Example of HiveQL query that creates one of those tables in the database *Traffic* are shown in Figure 4.

```
CREATE TABLE bocke(counter_ID STRING, counter_name STRING, X_coordinate STRING, Y_coordinate STRING,
ordinal_number STRING, d STRING, t STRING, loop_number STRING, direction STRING, vehicle_category STRING,
vehicle_speed STRING, vehicle_length STRING)
ROW FORMAT DELIMITED
FIELDS TERMINATED by '\t'
stored as textfile:
```

Fig. 4.
HiveQL query that creates a table bocke in the database Traffic on the Apache Hadoop platform

We “filled” the tables with the data from text files that are stored on HDFS using the HiveQL queries such as one shown in Figure 5.

```
LOAD DATA INPATH '/user/admin/Bocke.txt' OVERWRITE INTO TABLE bocke;
```

Fig. 5.
HiveQL query that transferred the data from text file Bocke.txt on HDFS to table bocke in the database Traffic

After that, we created a table named *all_counters* in the *Traffic* database in which we were able to move all the data from all 9 tables (of the database) with the help of HiveQL (Figure 6).

```
CREATE TABLE all_counters(traffic_counter_location STRING, longitude STRING, latitude STRING, direction STRING,
vehicle_speed STRING)
ROW FORMAT DELIMITED  FIELDS TERMINATED by '\t'
stored as textfile;
```

Fig. 6.
HiveQL query that creates a table all_counters in the database Traffic on the Apache Hadoop platform

On Figure 7 is shown one of the queries that copy the data from one of the tables in database *Traffic* to table *all_counters* in the same database.

```
INSERT INTO TABLE all_counters SELECT counter_name, X_coordinate, Y_coordinate, direction, vehicle_speed FROM bocke
WHERE CAST(TRIM(vehicle_speed) AS TINYINT) > 30;
```

Fig. 7.
HiveQL query that copy the data from table bocke to table all_counters in the Apache Hadoop database Traffic

Figure 8 shows a query that calculates some of the indicators, such as: the mean, maximum and minimum value of the vehicle speed during the 2015. year at a counting place Bocke.

```
SELECT traffic_counter_location, longitude, latitude, direction, ROUND(AVG(vehicle_speed), 2) AS AVERAGE_SPEED,
MAX(vehicle_speed) AS MAXIMUM_SPEED, MIN(vehicle_speed) AS MINIMUM_SPEED,
FROM all_counters WHERE traffic_counter_location="Bocke" AND vehicle_speed > 30
GROUP BY traffic_counter_location, longitude, latitude, direction;
```

Fig. 8.
HiveQL query that calculates the mean of the vehicle speed during the year at a counting place Bocke

By executing the appropriate HiveQL queries on the Apache™ Hadoop® platform, for each traffic counter location, road safety performance indicators related to the speed were calculated. Results of these queries are shown in Table 1. For example, known equation (1), that is used to calculate the standard deviation, we are transformed into the appropriate HiveQL query by which we calculated the standard deviation of the vehicle speed.

Table 1
Road safety performance indicators related to speed by traffic counter location in 2015. year

Traffic counter location	Average speed (km/h)	85th percentile of speed (km/h)	Standard deviation of speed (km/h)	Coefficient of variation	Percentage of vehicle speeds above limit (%)	Percentage of vehicle speeds above limit for more than 10 km/h (%)	Average speeding (km/h)
Alibegovac	52,77	57	8,86	0,17	57,29	18,29	8,58
Bocke	60,72	68	9,38	0,15	89,04	48,49	12,52
Bulevar Evrope 3	72,40	87	15,18	0,21	91,61	76,59	24,73
Klisa	65,11	76	11,32	0,17	92,36	64,14	16,64
Paragovo	65,46	77	12,89	0,20	91,59	62,95	17,35
Šančevi	64,12	75	11,45	0,18	89,32	61,66	16,32
Somborski bulevar	44,07	50	8,62	0,20	19,32	4,24	7,08
Tunel	74,54	88	14,05	0,19	86,44	78,50	27,82
Vojvode Stepe	54,71	62	8,41	0,15	68,45	24,91	8,95

$$\delta = \sqrt{\frac{1}{N}\sum_{i=1}^{n}\left(x_i - \overline{x}\right)^2} \tag{1}$$

Where; σ: standard deviation of all measured speeds of the vehicles at one counting place during one year (km/h), N: the total number of the measured speeds of vehicles at one counting place during one year, x_i: measured speed of one vehicle (km/h), $\overline{x}$: the mean value of all measured speeds of the vehicles at one counting place during one year (km/h). HiveQL query for the calculation of standard deviation of speed at counting place named Bocke is shown on the left side of Figure 9. On the right side of Figure 9 is shown the results of the mentioned query.

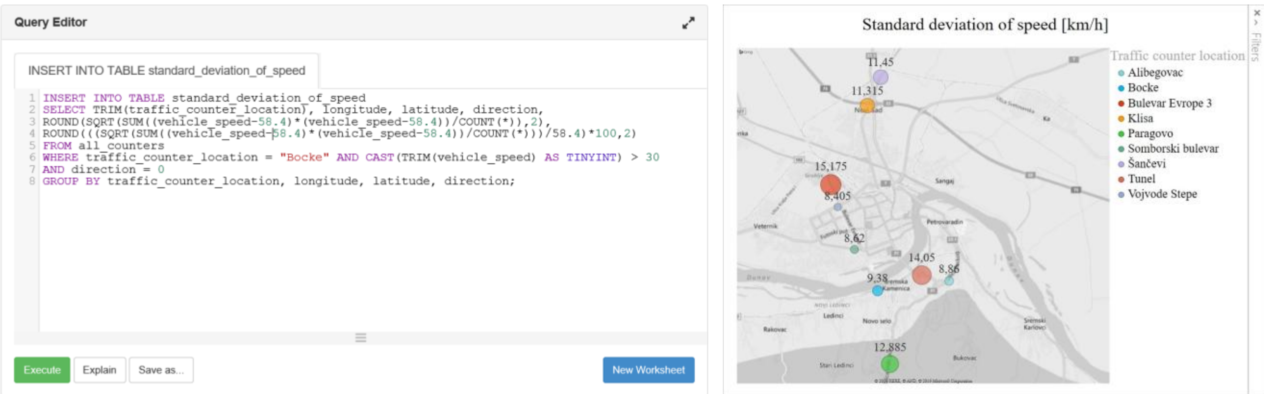


Fig. 9.
HiveQL query for the calculation of standard deviation of speed and his results geolocated on the road map

Figures 10, 11, 12 shows Microsoft Excel Power View worksheets that graphically represent the calculated values some of the road safety performance indicators related to the speed.

5. Conclusion

In order to become familiar with Big Data technologies in the field of speed analysis, we have developed Big Data solutions that enable the storage, processing and graphical visualization of data generated by traffic counters on the roads and streets in the Republic of Serbia. We used the Apache Hadoop Big Data platform to store and process all the data which could not have been performed using the Excel. Then we displayed the results of data processing, which we made using Big Data technology, specifically the tabular and graphic representation in Excel. In this research, we have been convinced in the power and efficiency of Big Data technologies, especially when it comes to the conduction of "SQL-like" queries over massive amounts of data. In addition, we have been assured in the ability to connect Excel worksheets with the Big Data sources, as well as an enormous capability of Microsoft Office Excel 2013 tools in the field of visualization and geo-location of data. Due to the fact that traffic generates huge amounts of data, which is often necessary to graphically display and geo-locate, the best solution is imposed by Big Data technologies in cooperation with the Excel.

INTEGRATED REAL-TIME SATELLITE POSITIONING AND COMMUNICATION SYSTEM FOR RAILWAY APPLICATIONS

Bogdan Pavković[1], Lazar Berbakov[2], Cristian Ulianov[3], Paul Hyde[4]
[1,2] Institute Mihajlo Pupin, Belgrade, Serbia
[3,4] NewRail Centre for Railway Research, Newcastle University, Newcastle upon Tyne

Abstract: An integrated satellite positioning and communication system has been developed within the EU FP7 funded project SPARTACUS, to provide live tracking and coordination of critical assets in a variety of different operational environments. This paper describes the system and the integration of its components to meet the specific requirements of operating in rail transport environment. The functions of each integrated component, as well as the operation of the overall system is presented. The technologies used to generate accurate positional data from the Global Positioning System (GPS) and inertial navigation (for when there is no satellite reception for the GPS system) are described. The article also describes the generation of the positional data, the technologies for communicating the positional data from each monitored asset via wireless propagation of the information between adjacent vehicles to a collection and communication unit on the train. The technologies for the continuous communication of the collected positions of the monitored assets in the train with remote logistics databases using terrestrial, cellular mobile networks, and satellite communications, with a "Smart Link" feature to automatically select the most efficient mode of data transfer are further presented. The integration of these technologies to produce a system to meet the specific requirements for operation within the rail transport environment is discussed. Potential applications of the system in rail sector are proposed and discussed.

Keywords: satellite positioning, GPS, tracking, communications, railway assets.

1. Introduction

In many areas of governmental and legislative policy making there is a general move to encourage modal shift from road transport of goods to rail transport. The main reason behind this is to obtain the environmental benefits of rail transport, which is more energy efficient than road transport in terms of the energy required to transport a given mass of goods, particularly where a collection of consignments can be consolidated onto a single train for a significant portion of a long distance journey, rather than a large number of road vehicles. Consolidating a large number of consignments onto a single train for a long distance journey can be more cost effective, as well as being more energy efficient than individual road transport journeys, at least as far as the cost per kilometre of the transport. However, transporting goods by rail is less flexible than using individual road haulage trucks for the entire journey, and usually involves transhipment costs, especially when either shipper or receiver lack direct access to railway. These transhipment costs might be a significant proportion of the total transport cost and be of a similar order of magnitude to the costs of operating the train itself. Practices such as containerisation aim to minimise the transhipment cost. With containerisation, the transport industry got rid of the manual sorting of most shipments and the need for warehousing. Containerisation also reduced congestion in ports, at the same time significantly shortening shipping time and reducing losses from damage and theft.

In order to manage a transport network effectively, it is necessary to be able to track and trace the consignments within the system; currently, this is generally only done by registering the passing of a container through certain points in the system (such as transhipment yards) and by association with a transport asset, the precise location of which may or may not be known. In order to further improve and optimise the handling of containers and integrate the transport process with the logistics and inventory systems of customers, it is necessary to precisely track of the location and current condition of containers, as well as regularly reporting of all the relevant data over communication networks in real time. Considering the scope of real-time tracking and tracing of goods, there are many potential applications within the railway industry for real-time tracking and positioning of railway assets, including the following:

- Tracking of assets for logistical purposes:
  - Freight customers; integration with business logistics systems;
  - Fleet management; locate fleet precisely without dependence on Infrastructure Manager, precisely track vehicle mileage and usage, and driver performance;
- Traffic management:
  - Locate trains without need for expensive and extensive lineside infrastructure;
  - End of Train Device to locate rear of train and ensure train integrity and track behind train clear.
  - Authorise train movements based on known locations and tracking of all trains: Optimise track flexibility;
- Asset management and condition monitoring (offline CM for traceability, online with communication):
  - Rail industry - location of track/infrastructure features/defects detected by trains;
  - Freight customers - location and condition of sensitive freight; temperature alarms for perishable items, tamper alarms for valuable freight;
- Safety and Emergency intervention and location:
  - Locate trains reporting an incident;
  - Alert assets in area of incident or hazard;

[3] Corresponding author: cristian.ulianov@ncl.ac.uk

- Locate hazardous freight (possible inclusion of condition monitoring).

The problem of precise tracking and tracing of freight trains has already been investigated by different research groups. In paper (Reason, 2010), the authors offer an overview of a concept for implementation of intelligent telemetry system for railway environment, and describes a small scale test implementation of the concept. The authors present details and a set of preliminary proof-of-concept tests of the following functionality: real-time tracking and telemetry of sensorial readings (temperature, humidity, open state), and tackle the issue of ghost wagons – railway elements misplaced in the vast space covered by the railway network of the USA. The paper proposes a reactive system for wireless detection of ghost wagons where the presence of those wagons in circulating trains would detect when passing by certain locations, and the presence of the lost wagons reported to authorities.

The FP7 funded project SPARTACUS (http://www.spartacus-project.eu/) had a goal to provide a complete solution for overall security in emergency management through efficient Location Awareness and Logistic tools that can be deployed during disaster, and which have other applications. The aim of the SPARTACUS project was to design, develop, and demonstrate in real-world scenarios a system for tracking and tracing relief goods, critical transport assets, and first responders in order to assure their safety and efficient crisis management operation. SPARTACUS aimed to provide anytime and anywhere localisation of assets through combined use of existing GNSS and innovative inertial navigation systems. SPARTACUS solutions merged geo-referenced multimedia and situation reports with satellite maps to provide a Situation Awareness and a Decision Support System, and enabled real-time updates and information exchange through a portable and independent communication unit (3G/4G/WiFi/TETRA-alike) with satellite back-hauling.

The paper describes the system architecture, the integration of its components, and the customisation of the system to apply the technologies developed to the rail transport environment and to meet the operating requirements of that application. The technologies that are used to generate accurate positional data from the Global Navigation Satellite System (GNSS) and inertial navigation (when there is no satellite reception of GNSS) are presented. In particular, the paper describes the generation of the positional data, the technologies for communicating the positional data from each monitored asset via wireless medium between adjacent vehicles to a collection and communication unit on the train. The integration of these technologies to produce a system to meet the rail operational requirements is discussed. Finally, present some results obtained during the demonstration campaign at Faurei railway testing centre in Romania.

2. State of the art of intelligent railway tracking and telemetry systems

2.1. State of the art on communication systems

Current state of the art communication solutions supporting railway tracking could be divided in the following groups according to the communication topology deployed:

Infrastructure based: solutions from this group rely partially or entirely on communication infrastructure installed along railway tracks. Available infrastructure enables discrete communication interactions when railway composition enters the limited communication range for short intervals upon train passages. Optionally, continuity of communication can be provided with additional remote communication technologies (cellular and/or satellite). Two types of systems have been mostly described in the literature, i.e.:

a) ***GS1 RFID railway standardised technologies*** (Halas, 2014): GS1 recommends the use of short-range RFID technology (up to 10 m) to dually provide identification and precise discrete position of all railway elements. GS1 RFID system has two parts: RFID readers (provided along railway tracks at limited number of locations with power supply and wired communication available) and RFID miniature end-devices (passive tags, harvesting and reflecting energy from RFID readers) deployed on moving railway elements. When a railway composition passes nearby RFID reader, all elements are uniquely read, identified, and transferred to control centre with the fixed position of the reader. Train timing and position can be inferred from consecutive reader reports.

   *Proficiencies**:***
   - Efficient identification: RFID reader identifies all railway elements even at high speeds
   - Robust: Position independent identification of arbitrary number of tagged elements (up to certain limit) Reduced energy footprint: RFID tags are passive battery-powered; RFID reader is grid powered.
   - Miniature size: RFID tags are size of a tiny sticker ensuring easy placing on railway elements.

   Constraints (SPARTACUS design avoids them):
   - Infrastructure based: RFID readers are provided at many locations, even when tracking is not needed; On the contrary, SPARTACUS provide portable/mobile units to be deployed on demand.
   - Limited tracking resolutions: RFID readers are built at limited number of locations, thus limiting resolution of tracking. SPARTACUS provides any-where any-time real-time continuous tracking.
   - Limited tracking history: passive RFID tags have scarce storing / logging capabilities where SPARTACUS solution provides dedicated memory for necessary logistic and tracking logs.

b) ***RAJANT Railway MESH*** (Hellhake, 2016): RAJANT deploys bridging devices (combined wired and wireless) at fixed positions along a railway track. Devices provide connectivity to both wired backbone and wireless mesh deployed on railway composition. Bridge devices enable tracking and status information upon train passage. Conversely, when bridge devices are unavailable, the rest of MESH deployed at railway composition operates seamlessly, preserving connectivity.

Proficiencies:
- High bandwidth: accommodate advanced applications (tracking data collection, audio, video, etc.)
- Efficient M2M and data collection: devices interconnect mutually, with automatic reconfiguration and reporting path healing in case of node disconnection, thus ensuring robustness.

Constraints (SPARTACUS design avoids them):
- High battery consumption: with greater bandwidth comes increased power consumption
- Limited tracking resolutions: similarly to GS1 RFID the resolution of tracking depends on the density of deployed bridges. Mediated with deployment of additional GNSS and INS equipment on railway composition.

Infrastructureless: solutions from this group are independent from any kind of communication or power infrastructure that makes them excellent match for EM scenarios. Solutions offer independent portable modules that can be deployed on request in different missions or on regular basis for regular railway tracking and logistic.

Tracking device meets remote communication: each tracking device (GNSS with or without INS) features a long distance communication unit (RF, cellular, and/or satellite). Network forms a star topology converging at a central remote collection centre where each tracking terminal serves as communication reporting end-point. Direct local communication (M2M) is not enabled, and eventual exchanges always transit through central communication hub. Currently there is an abundance of solution readily available on the market in variety of forms, such as (listed by the increasing order of available features and/or integration):
- A standalone communication device granting possibility for expansion with external GNSS module;
- Chipsets directly integrating GNSS and cellular capabilities (Kaul, 2014);
- Furthermore, numerous vendors offer terminals for deploy-out-of-the-box with colour displays and graphical interface integrating GNSS with cellular (Cats, 2016), or satellite communication (Dold, 2015) (Niehaus, 2015);
- Finally, a complete solution strives to provide integration with logistic software (web interface and cloud storage) (Amsted, 2016) with eventual integration with sensors (Waukesha, 2015);

Solutions from this group offer standalone devices with independent means of communication for each tracking unit - a high-end solution that is highly adapted for individual and important assets tracking. Nevertheless, they are not necessarily well adapted to massive railway container shipping since similar solutions do not scale well due to their overall price, higher power consumption and battery maintenance. SPARTACUS tackles these challenges by decoupling independent remote communication from low-power local wireless sensor collection.

2.2. State of the art on tracking systems

Train and container localisation/positioning is a crucial task for railway transport, especially in relation to safety-relevant issues or safe-critical operation (either automated or not) of special assets and goods. Nowadays, train positioning along the railways net is accomplished by ground fixed installations, typically track-side equipment, in combination with positioning sensor systems placed on-board the trains (for details see the description of the European Train Control System, ETCS, Level 2 in (Terry, 2012)).

The functioning principle of these types of systems (Bailey, 1995), (Albrecht, 2013) is basically based on wireless exchange of data and is the following: beacons, devices that behave like transponders, are placed along the track at known pre-established positions. They can be considered as Radio Frequency IDentification (RFID) devices and can be either of passive type, working as inductive transponder without need of electrical power supply, or active devices powered by batteries. When the train crosses a beacon, its on-board equipment triggers the beacon’s transponder which transmits a radio data flow to the train containing its position fix and other information. By receiving these data, the train equipment can determine its position at the time of data reception, within a certain accuracy depending on the train speed and the accuracy of the beacon known position. In addition, the passage of the train over the beacon, hence the train position, can be acquired by the train traffic control system via the wired link connecting each beacon to the train control centre network.

The positioning of a train via beacon, as described, has three main disadvantages:
- it is intrinsically discrete in time, hence no continuous position of the train is available;
- it is affected by data latency depending on the train speed, so reducing the accuracy of positioning;
- it requires a ground infrastructure.

As to the first point, the adopted method to obtain a continuous position solution of the train is to use the data from an on-board odometer (wheel counter) to propagate in time the position estimate between two fixed balises. The accuracy of the propagated position typically decreases with time (or distance between two fixes) due to possible wheel slips or the drift caused by the imperfect knowledge of the circumference of the wheel.

In order to completely overcome the three listed drawbacks, some interesting alternatives have been proposed (see PiLoNav project in (Mahlknecht, 2007)) - the main one is the introduction of a train positioning system based on only on-board available data and independent by any external ground infrastructure. This system is designed on a multisensor on-board positioning system that performs a data fusion between GNSS data, Inertial Measurement Unit (IMU) data, and additional sensors such as an optical sensor and a laser scanner.

The optical sensor is based on LEDs that illuminate the railheads during the train motion: diffraction gratings processing allow for a quite accurate and slip-free train speed measurement; speed numerical integration provide the run distance. The laser scanner is used in order to determine transversal (lateral) position of the train with respect to the direction of motion, so providing an automatic rail track identification, together with side signals recognition. This sensor redundancy has a twofold aim: 1) to improve the position accuracy by a calibrated data fusion algorithm that weights in an optimal way the information provided by each sensor in order to get the best position solution; 2) to increase the reliability and robustness of the system. In addition, a map matching process can be accomplished to force the train position solution to fit to the real rail shape, so further improving the accuracy of the positioning. The disadvantage of the map matching consists in the difficulty to equip each train with a georeferenced, detailed, updated and accurate map of the rail net, whose availability is not always guaranteed.

On the other hand, single container positioning is not a much exploited field. The most up-to-date widespread solution consist of RFID passive tag installed on the wall of a container that provides to an operator passing in front of it some status data such as Identifier, Temperature, and so on. More advanced devices also include a tracker based on low cost GNSS receiver that can provide a rough container position estimate, in case of GNSS signal availability.

The container and train positioning system proposed in this paper is based on a *multisensor framework* too, together with a *data fusion process*. Nevertheless, in the proposed system no pre-stored maps are needed nor external infrastructure or additional on-board sensors in addition to those already envisaged by current projects as PiLoNav. As opposed, a data fusion between a high quality on-board freight train positioning system and low cost container tracking units carried by the wagons of the train is performed. This data fusion exploits the kinematics constraints of the train geometric configuration, used as an additional source of information, and aims to provide better, refined and more accurate positions of both the already accurate locomotive position (which integrates good quality GNSS data and odometer/IMU data) and that of the containers (that is not good when considered singularly).

One of the main features of the proposed system is that the increased accuracy derived by the multisensor-kinematic-constrained framework increases also the robustness and the integrity of the position solution and the system safety.

3. SPARTACUS system architecture

This section presents the SPARTACUS system architecture. Figure 1 shows a holistic overview of the main composing building blocks, their mutual relationship, and points of interaction with intended end-users. SPARTACUS system architecture should serve as a clean graphical overview and a simple starting point to understand how the system is conceived and how information flows without going to the detailed technical specifications. Bidirectional information exchange flows along both wireless and wired networks and links. Specific technologies, standardised protocols, and supported interfaces are concealed in the SPARTACUS overall architecture and are presented in more details in the subsections dedicated to the specific SPARTACUS subsystems.

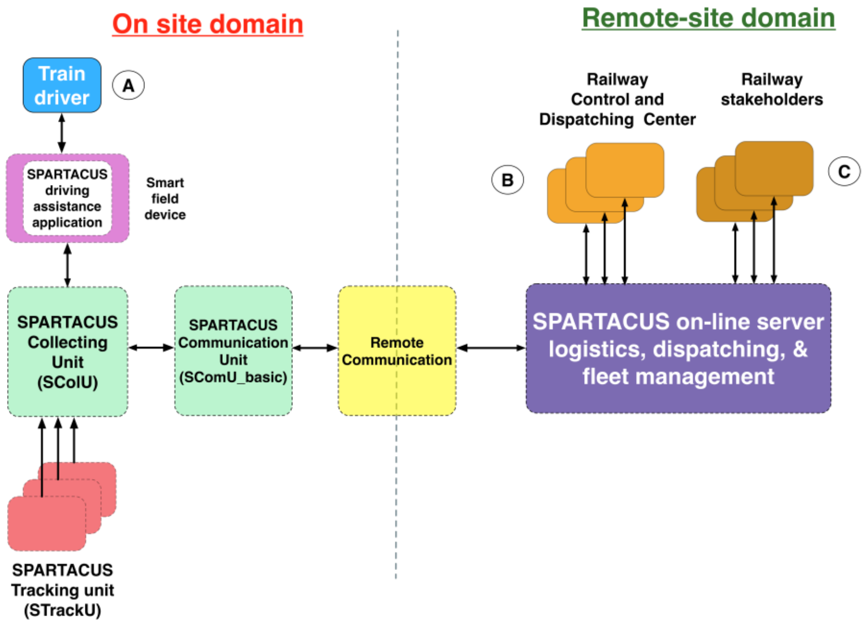

Fig. 1.
SPARTACUS system architecture

SPARTACUS architecture was kept as general as possible to be easily upgradable and to respond to applications with similar needs. SPARTACUS architecture follows modular design, where each building block regroups technologies providing complementary or similar functionalities.

SPARTACUS system architecture takes into account a clear differentiation between on-site and remote site domain as defined by user profiles. On-site segment can be seen as the sensing and acquisition of information about transport and disaster site environment itself. On-site segment includes local and remote communication means along with low-bandwidth clients for visualisation and direct situation feedback. Remote site can be seen as a centralised point for information collection, further analysis, processing, and information fusion for situation awareness and decision support.

3.1. Local communications subsystem

The communication architecture of the SPARTACUS Collection Unit (SColU) is shown in Figure 2. The focus is on communication channels offered by SColU and interconnection points with other units in the SPARTACUS system.

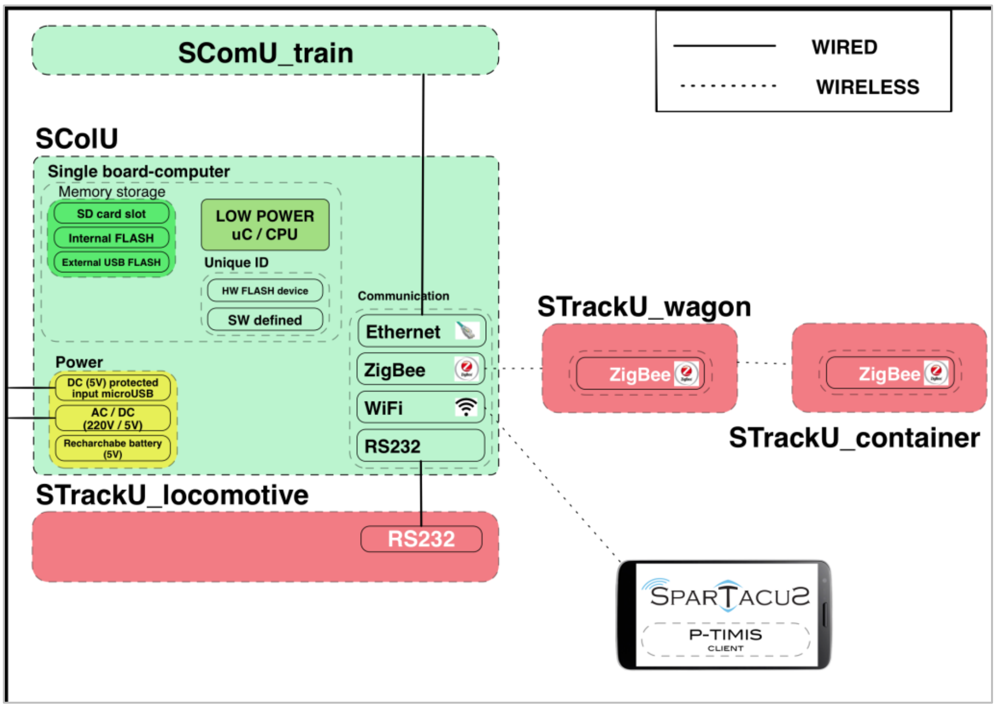

Fig. 2.
SColU communication architecture

The aim was to build, collocate, and interconnect in the same protective suitcase/box several units - SComU, SColU, and STrackU (SPARTACUS Communication, Collection, and Tracking Unit respectively). Particular design choice stems from the strategic importance of the locomotive as the principal element in the transport composition holding a train driver. SColU provides several means of communication to interconnect with the rest of the system. SColU connects over wired link to the elements in its physical vicinity. Bidirectional information exchanges between SComU and SColU will be carried over a standard Ethernet connection supporting transfers of potentially large volumes of collected tracking and tracing data. On the other side, SColU interfaces to STrackU_locomotive (developed as a stand-alone unit, and produced by *SBG Systems*, a partner in SPARTACUS consortium), over a standardised RS232 serial link. Serial wired link (RS232) provides sufficient bandwidth to accommodate periodic samplings of tracking and tracing information at maximal rate of 200Hz. Lower rate readings can be directly configured at the unit. On demand asynchronous access (triggered request) is equally available. SColU provides as well wireless interfaces for elements that are either physically located further away or when it is more favourable and practical to connect over wireless channel.

Highly dynamic railway environment with frequent changes of transport asset composition (wagons and containers leaving / joining) is ill-suited for wired cable connections. SColU provides both a standardised WSN (ZigBee) and WLAN (Wi-Fi) connections. SColU accommodates a ZigBee PAN coordinator (gateway / sink) that serves as a central point for collection of tracking and tracing data from STrackUs (wagon and containers) equipped with ZigBee modules accordingly configured as ZigBee routers and ZigBee end-devices, respectively. Low-power, low-bandwidth ZigBee technology offers a sufficient throughput (a nominal 250kbit/s) to accommodate a periodic tracking and tracing reporting from STrackUs located on wagons and corresponding containers. Frequency of STrackU on wagons and containers will be at lower frequency compared to those on the locomotive. SColU can provide a secured Wi-Fi - IEEE 802.11 b/g/n.

When SComU is available and connected to SColU through a primary Ethernet link, a WLAN AP will be provided only by SComU for energy conservation reasons. Otherwise, it will be provided by SColU, configured and limited for exclusive communication between authorised railway personnel and local server hosted at SColU. A primary user, e.g., the train driver, will be able to monitor the state of the railway composition in real-time through the mobile application on COTS smartphone. Furthermore, WLAN AP provides an efficient way for any authorised personnel to securely access and download a local historical copy of collected tracking and tracing data stored on SColU, both when deployed on a train and post-mission. Furthermore, SColU will provide a backup wireless link to connect to SComU if primary Ethernet link is not available or not working. It could be equally performed either through an additional Wi-Fi interface or by using the same physical interface but enabling a virtual interface. A trade-off between energy consumption (several independent physical interfaces) and bandwidth repartition (single shared physical interface) needs to be further established during the implementation phase.

3.2. Remote communications subsystem

The network architecture of the SPARTACUS Communication Unit (SComU) is depicted in Figure 3.

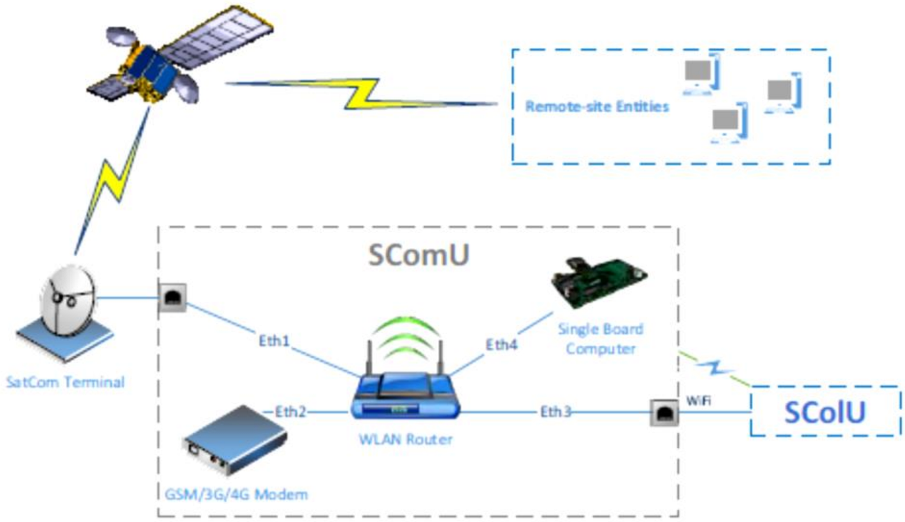

Fig. 3.
SComU remote communication subsystem architecture

The SPARTACUS Communication Unit (SComU) consists of several network elements that all aim at interconnecting units together and also allowing the support of different networks. The communication towards the remote-site entities is made through remote communication based either on a terrestrial network when available, or on a satellite network. The connection to the terrestrial network is done using a Long Term Evolution (LTE) modem which simply acts as a client in the 4th Generation (4G) network, exactly like a 4G smartphone would do. This LTE modem allows interconnecting other devices via Ethernet such that it is possible to access the 4G network. In our case it is foreseen to connect the LTE modem to a router such that the 4G connection is shared with the other devices connected to that router. In the same way, the satellite communication (SatCom) terminal consists of a satellite modem and of an antenna also allowing sharing its connection via Ethernet. This way, the SComU can access the “outside world”, also named the Wide Area Network (WAN), using either the satellite connection or the terrestrial 4G connection. It is foreseen, in the framework of the rail application, to make use of the Broadband Global Area Network (BGAN which is an Inmarsat service) for the satellite connection. BGAN offers the possibility to benefit of a bandwidth in the magnitude of 256 kbps (upload and download) while using relatively small satellite modem and satellite antennas (patch antenna in the L-Band). In terms of communication, the SComU shall also provide a local wireless network based on the conventional and well spread Wireless Fidelity standards (Wi-Fi). The SComU also supports local wired connections based on Ethernet (conventional RJ45 cables). Both Wi-Fi and Ethernet are provided by a Wireless Local Area Network (WLAN) router which acts as a central node of the star network topology.

3.3. Positioning subsystem

Positioning subsystem (STrackU) fulfils the following roles: continuous tracking and tracing (combined use of GNSS and INS readings), communication with SColU, and finally acquisition of local sensor readings (container monitoring e.g., temperature, humidity, or detection of a door open status).
STrackU will dispose with both wired (RS232/RS433) and low-power wireless (ZigBee) communication means. Both means offer security mechanisms to encrypt and securely transfer data. Wired connection will be used for the case where STrackU and SColU can be collocated in the same casing. Majority of communication functionalities described for SColU (periodic reporting and triggered requests) will apply as well for STrackU to complete bidirectional communication flow. Entire WSN ZigBee network will follow a convergecast tree topological structure, specifically optimised for collecting periodic reports from potentially large number of end-devices (STrackUs). Additional

advantage of convergecast topology is an intuitive aggregation strategy - intermediate levels, (STrackU_wagon) could decide to fuse tracking and tracing readings when they do not differ substantially. Instead of simply forwarding of each single packet from STrackU_container, energy and bandwidth savings could be achieved by intelligently combining several packets and forwarding them conjointly. Different "flavours" of STrackU are building a convergecast topology by fulfilling a specific device role defined by the ZigBee standard.

- STrackU_locomotive with SColU, as a collecting gateway is configured as a ZigBee PAN coordinator and fulfils several roles: apart from collecting tracking and tracing readings from the entire WSN, it authorises the joining process for other new coming devices and remotely polling other subordinate nodes;
- STrackU_wagon was configured as ZigBee Router, and it serves as an intermediate device, relaying end-devices with a gateway. Additionally, it could provide aggregation feature for sub-network nodes;
- STrackU_container was configured as a ZigBee End-device due its logical belonging to the end of reporting chain. It generates periodic reports of both tracking readings, as well as of available environmental data provided by external sensors (not inherent part of STrackU, optionally provided by end-users).

4. Test implementation of the SPARTACUS system in railway environment

The application of the technologies developed within the SPARTACUS project to the railway environment has been initially tested by a trial installation carried out at a full scale railway test site. These tests are described in the paper "Testing and Evaluation of Real-time Satellite Positioning and Communication System in Rail Transport Environment" by Hyde et. al., which was presented along with this paper at the ICTTE 2016 Conference. That paper describes the successful installation and testing of a railway vehicle positioning and position communication system using the technologies described in this paper. It also describes how, after the adaption of the system to railway conditions and environmental characteristics, and refinement of the system hardware and software configuration, it was shown that the system was able to communicate the position of all of the vehicles in the train to a remote location in near real-time. In those tests, the accuracy of the positioning data was demonstrated to be sufficient for the overall aims of the project, which is to achieve critical asset tracking for logistical purposes in a variety of applications.

5. Full scale demonstration of the system

Since the initial testing and adaption of the system, which was described in the paper referred to in the previous section, a further test installation and demonstration of the system has been carried out, and some preliminary results are available. The demonstration of the system was performed in September 2016 at Romanian Railway Authority (AFER) testing centre, in Faurei, Romania. The system was tested on the big ring of the testing centre, which has a total length of lines of 13.7 km. The train composition consisted of a diesel locomotive and two wagons, where the system components have been installed as follows:

- SComU+SColU have been installed in the locomotive cabin with satellite and GPS antenna mounted on the roof;
- 4 STrackU have been installed on wagons (by using magnetic pads), where three of them were configured as STrackU_wagon and one configured as STrackU_container (as shown in Figure 4).

Locomotive and 2 wagons used for testing

SComU and Ellipse module
installation in the locomotive

Installation of the STrackU on the roof
with magnetic pads

Fig. 4.
Testing setup at full scale demonstration at Faurei test centre

Before the testing, all the devices have been switched on, and both local ZigBee and remote connection over LTE were automatically established. Once the train started its ride, the train path could be observed on the CTAT web portal, as shown in Figure 5.

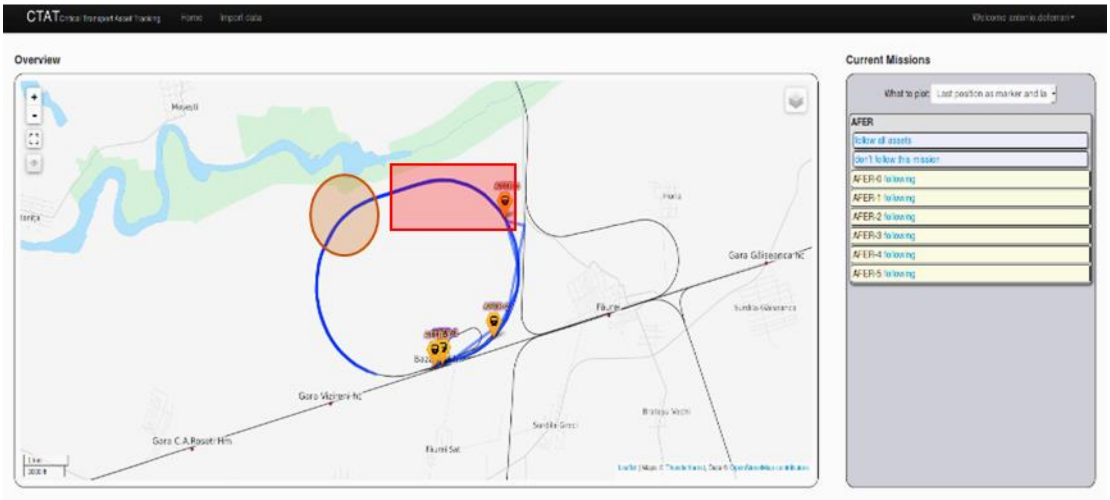

Fig. 5.
Train path observed on CTAT web portal

During the ride, a GNSS signal outage was simulated by disconnecting the antenna for two minutes where the train was correctly tracked during the whole outage period (red rectangular zone in Figure 5). An outage of the LTE network between two base stations (orange circular zone in Figure 5) was also for a short period, during which SComU automatically switched to satellite link, providing uninterrupted network connection between on-site and remote-site domains. As can be seen from Figure 5, the track perfectly followed the railway track even in periods of GNSS signal outages.

6. Conclusion

An integrated tracking and communication system to be used for continuous railway assets tracking was developed, and is presented in this paper. The tracking is provided by intelligent sensor fusion between GNSS and INS that provides tracking even in locations with GNSS signal outage such as urban canyons and tunnels. The communication is divided into local and remote domain in order to provide a good balance among energy efficiency, cost and robustness. The system has been tested at Faurei railway testing centre in Romania, where it proved to be highly robust to GNSS and network signal outages, at the same time providing high accuracy and continuity in train tracking.

TESTING AND EVALUATION OF REAL-TIME SATELLITE POSITIONING AND COMMUNICATION SYSTEM IN RAIL TRANSPORT ENVIRONMENT

Paul Hyde[1], Cristian Ulianov[2], Bogdan Pavković[3]
[1,2] NewRail Centre for Railway Research, Newcastle University, Newcastle upon Tyne, UK
[3] Institute Mihailo Pupin, Belgrade, Serbia

Abstract: A satellite positioning and communication system has been developed within the EU FP7 funded project SPARTACUS, to be applicable to different use cases where live tracking of critical assets and a detailed and accurate operational picture is essential to the operation of those assets. This paper presents the testing of the satellite tracking system in rail transport environment. The test program was designed to verify the core functionalities of the system and its performance, and also to verify that the system could be effectively customised and deployed to the real-time tracking and coordination of critical assets in railway environment. The tests were carried out in controlled conditions in a full-scale railway environment to represent an operational railway. The functionalities tested included the ability of the system to communicate the rail vehicles' positions, determined from the Global Positioning System (GPS) and inertial navigation, via terrestrial and satellite communications from a collection unit on the locomotive, and the system capability to continuously update the data in real time. Another tested feature was the ability of the system to wirelessly communicate the positions of each of the vehicles in the train, via propagation of the information between adjacent vehicles, to the communication unit on the locomotive, so that the positions of all of the tracked assets on the train could be communicated. In addition to the tracking of rail vehicles, the system communication capability, to provide rail personnel in a control centre and on the field with live updates of the vehicles' position, was also tested. The tests showed that the system customisation was effective in enabling the prototype system to be installed and operated in a controlled railway environment, and that the system is able to perform the functions of real-time tracking of monitored assets and communication of data to operational personnel.

Keywords: railway assets, testing, satellite tracking, GPS, communications.

1. Introduction

There are many potential applications within the railway industry for real-time tracking and positioning of railway assets, including the following:

- Tracking of assets for logistical purposes:
  - Freight customers; integration with business logistics systems,
  - Fleet management; locate fleet precisely without dependence on Infrastructure Manager, precisely track vehicle mileage and usage, and driver performance.
- Asset management and condition monitoring (offline CM for traceability, online with communication):
  - Rail industry - location of track/infrastructure features/defects detected by trains,
  - Freight customers - location and condition of sensitive freight; temperature alarms for perishable items, tamper alarms for valuable freight.
- Safety and Emergency intervention and location:
  - Alert assets in area of incident or hazard,
  - Locate trains reporting an incident,
  - Locate hazardous freight (possible inclusion of condition monitoring).
- Traffic management:
  - Locate trains without need for expensive and extensive lineside infrastructure,
  - Authorise train movements based on known locations and tracking of all trains: Optimise track capacity and flexibility,
  - End of Train Device to locate rear of train and ensure train integrity and track behind train clear.

A number of projects in the past have attempted to develop satellite tracking for railway industry applications. Some of the earlier of these projects (GLORIA,2002; GADEROS, 2004; LOCOPROL, 2004) demonstrated the potential uses of satellite tracking, however the performance, reliability and dependability of the positioning given by the systems developed was often insufficient, particularly for safety critical traffic management. More recently the SATLOC (2014) project has developed and tested a rail traffic management system based on satellite positioning, compatible and compliant with the requirements for traffic management; however it is too early to assess the acceptance and uptake of this system by the rail industry.
The aim of the real-time satellite tracking system which is the subject of this paper was developed in the SPARTACUS (2016) project and was not intended to provide tracking of trains for traffic management, but to provide supplementary tracking that could be used for fleet logistics and customer freight tracking, as well as providing localisation of the train in emergency situations to support the response of emergency services and the railway operator. The objective of the EU FP7 funded project SPARTACUS was to develop tracking/positioning solutions for critical asset tracking and crisis

[2] Corresponding author: cristian.ulianov@ncl.ac.uk

management; this development was divided into three application areas, with the technical solutions being relevant to each application area and customised to suit the specific needs of each. The application areas are:

- To track, trace, and localise critical transport assets especially in times of crisis and in case of major failure of existing networks,
- To track the flow of relief support goods from the sending side to the receiving/end place,
- To support and ensure the safety of first responders in crisis management operations.

This paper concerns the testing of the technical solutions customised for the first application, specifically live tracking, tracing, and localising of railway assets in real-time.
The architecture of the satellite positioning technology and communication technology used in the SPARTACUS system to provide satellite tracking is as follows:

- *Tracking Units:* Tracking units are fitted to each rail vehicle in a train (and potentially cargo units such as containers as well), these consist of as Global Navigation Satellite System (GNSS) antenna which is connected to a navigation system with inertial sensors, a miniature computer to receive the position information, a ZigBee wireless transceiver module to create a low power wireless network on the train, and a battery power source. The inertial sensors in the navigation system give the tracking unit a dead reckoning capability when GNSS signal is lost,
- *Collection Units:* The Collection Unit is fitted to the locomotive and has a ZigBee wireless transceiver module and a miniature computer to collect the position data from the Tracking Units in the network (that is, the train). The position data collected from the Tracking Units is stored and sent to the Communication Unit on the locomotive which it is hard wired to,
- *Communication Unit:* The Communication Unit transmits position data to a database to enable real-time tracking of the train. The Communication Unit consists of a computer controller linked to a terrestrial 4G phone network and via satellite communications module with antenna, a smart link selection function selects most efficient data link (terrestrial or satellite) to ensure maximum communication coverage.

The tests described in this paper fit within the overall testing and validation strategy for the whole system in its different applications. The overall strategy included a three stages testing programme, including:

- 1st stage: the testing of functions of the individual components and sub-systems,
- 2nd stage: testing functionality of the integrated systems,
- 3rd stage: applying the system to realistic use case scenarios, as well as more extended tests.

The tests described here were part of the second stage and were intended to test the functionality of the integrated positioning and communications systems to verify that the system could be deployed in a real railway environment and the GNSS derived position of the transport assets (vehicles in the train) transmitted to remote servers allowing the train to be tracked in real-time.

2. Testing of Live Tracking Title

2.1. Test Installation

The railway environment represents many challenges to a system such as developed in the SPARTACUS project, e.g., the components must be sufficiently rugged, the separation between routes is limited (compared to aircraft for example) therefore the accuracy required to distinguish between them is high, trains can pass very close or inside structures which might interfere with communication and GNSS reception, etc. In addition to these precision location and general challenges, the electronic and wireless communication components must operate in an environment containing other systems and often surrounded by large amounts of metal. To represent the conditions and challenges of a real railway environment and test the functionality of the system under realistic conditions, the tests installation of the system on a real train was carried out at the testing facilities of NewRail at Barrow Hill Railway Centre U.K. The test installation consisted of a locomotive fitted with Tracking, Collection and Communication unit, and four tracking units fitted to wagons (represented by passenger carriages), the dual fitment of one vehicle with two tracking units was considered as representing a wagon carrying a shipping container, each with their own Tracking Units communicating their positions with the wireless network.
Figures 1 and 2 show the fitting of the Tracking, Collection and Communication unit to the locomotive, the satellite communications antenna being the white dome prominent on the roof of the locomotive in the middle of Figure 1, with the GNSS antennas either side. In Figure 2 the communication unit can be seen on the cab floor configured to be installed within a strong plastic flight case for protection, the integrated Collection and Tracking unit, including miniature commuter, navigation system and ZigBee network module can be seen on the far right, for the purposes of the test the system on the locomotive was powered from a 12V truck battery contained in the clear white plastic box on the left of the figure.

Fig. 1.
Photograph of the system installation on the locomotive showing the roof mounted antennas (satellite communications antenna in the centre and GNSS antennas either side)

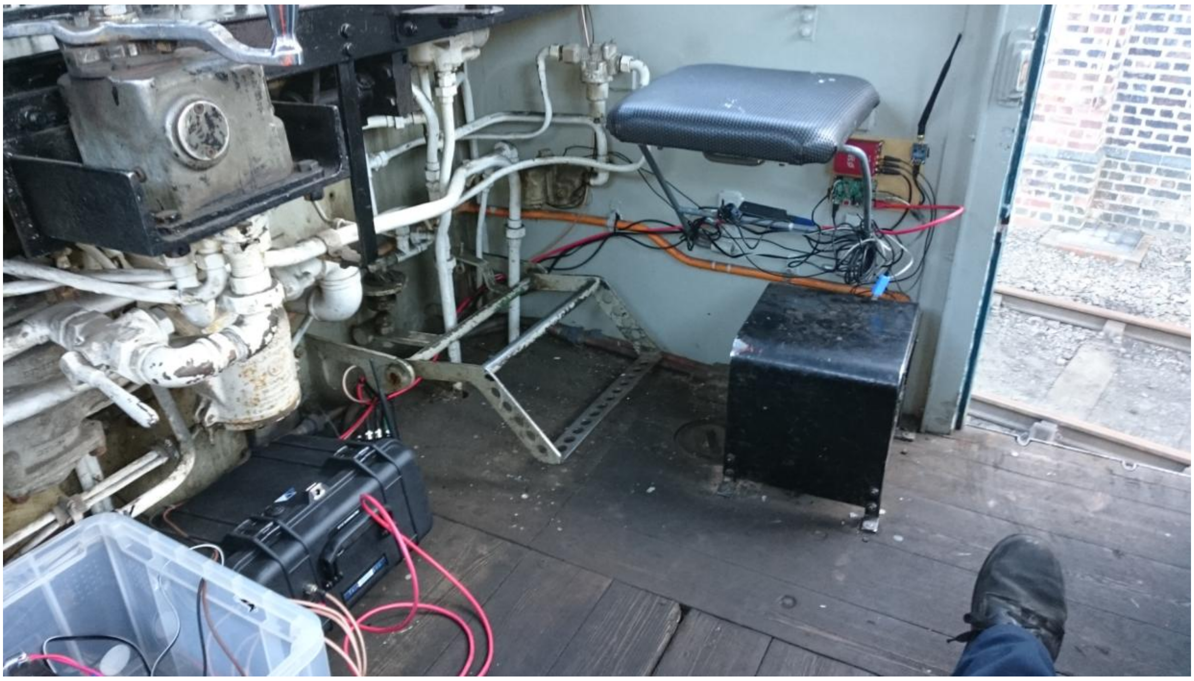

Fig. 2.
Photograph of the system installation on the locomotive showing the inside of the locomotive cab with the black communications control case under the locomotive control desk (on the left) and the tracking unit on the cab wall (on the right)

Fig. 3 shows the test train configuration with the locations of the units identified with labels, i.e., L for the Locomotive unit (as shown in **Error! Reference source not found.** and Fig. **2**.), W1, W2, and W3 relate to the position of the Tracking Units on wagons 1, 2 and 3 respectively, and C for the position of the Tracking unit fitted to wagon 3 (representing a Tracking unit fitted to a shipping container). The single GNSS antenna for the tracking units installed on the wagons (units W1, W2, W3, and C) were installed on the roof of the vehicles above the tracking units' location with a clear view of the sky.

2.2. Test Procedure

The test procedure involved initialising the tracking system by turning on the Tracking, Collecting and Communication units and driving the train along a sequence of passes on different tracks on the site. The routes consisted of a main running line from which two other routes branched off. The total distance of all of the routes travelled by the test train was 1.6km, with the longest continuous run being 1km and the maximum speed 32km/h. The test was repeated a number of times, each time the sequence of train movements being carried out twice, once with the system set to send the position data of all of the vehicles using the terrestrial mobile phone network, and once with the system set to send the position data using the satellite communication link. The selection of the communication mode was carried out manually by overriding the smart link selection feature, as the conditions were such that the terrestrial mobile phone network would always have been selected, and it was desired to test the satellite communication mode as well.

Fig. 3.
Test Train Configuration showing location of units and the fitting of a Tracking unit to a rail vehicle (see text for meaning of labels)

3. Results

The test procedure was repeated a number of times, as the initial results indicated that various refinements to the system were required; although the units had been tested under laboratory or workshop conditions, the challenges of the railway environment and operating conditions required modifications to be made in order of the system to perform as required. One issue encountered was that the initial installation position of the Tracking units on the wagons (on the floor on the centreline) the signal strength of the ZigBee wireless modules was not sufficient to provide a stable network to send position data to the Collection unit. The position of the Tracking units was changed to that one shown in Fig. 3 (on a side window with the ZigBee antenna directed outside); this enabled a stable network to be created and the positions of the tracking units to be passed to the Collection unit. Another of the issues encountered was that the navigation system within the Tracking unit required a certain direction of travel and speed threshold to be reached for the system to initialise and collect GNSS positions. Initially the results showed that the accuracy of the position was poor; for example it was observed that the position data would start off at coordinates which coincided with the route of the track on the map, but when the train moved the position trace showing the position history of the vehicle showed it moving in a path with a similar shape to rails but diverging from the mapped location of the rails. In some cases the position reported for the vehicle would be as much as 20m from the mapped location of the railway track before a GNSS fix meant the position reported by the system snapped back to one that corresponded to coordinates along the railway track. The cause of this error was identified as a combination of three factors associated with the navigation system:

- The first of these factors was that the system has a set minimum speed threshold that the train must achieve for the system to initialise correctly. The test train was not able to reach the set speed threshold quickly enough, as the locomotive did not have enough power due to the initialisation direction requiring the train to climb a steep gradient.
- The second factor was that the inertial navigation component of the system has priority over the GNSS component for updating the position, except when the GNSS signal is very good.
- The third factor was that the motion profile of a train is significantly different from those in aviation, automotive and maritime transport (which the inertial navigation component was developed for). The principal difference is that the rates of acceleration in all directions and axis of rotation is significantly less in rail transport, therefore the errors in measuring these acceleration become more significant when it comes to calculating the heading and motion of a train.

The result of the combination of these factors was that initially the inertial navigation system was not accurately measuring the motion and heading of the train, as shown by the left image in Fig. 4. The bias towards the inertial navigation system for updating the position of the train meant that GNSS position was only being used when the signal was good, even if a lower signal strength might have provided a more accurate position than the inertial navigation system. This issue was resolved satisfactorily by reconfiguring the navigation system with a lower initialisation speed threshold, so that the system was able to initialise correctly during the first movement of the train and provide accurate position data (the right image in Fig. 4). The results from the final configuration of the system showed that it was possible for the position of the locomotive and wagons to be measured accurately, and for that data to be collected and communicated to the databases (both by terrestrial and satellite communication networks), so that the position of the train could be remotely displayed on a map and recorded. Both the terrestrial mobile network and satellite communications system were able to provide a good communication pathway to transmit the collected position data to the remote servers across all of the locations and speeds the test train travelled.

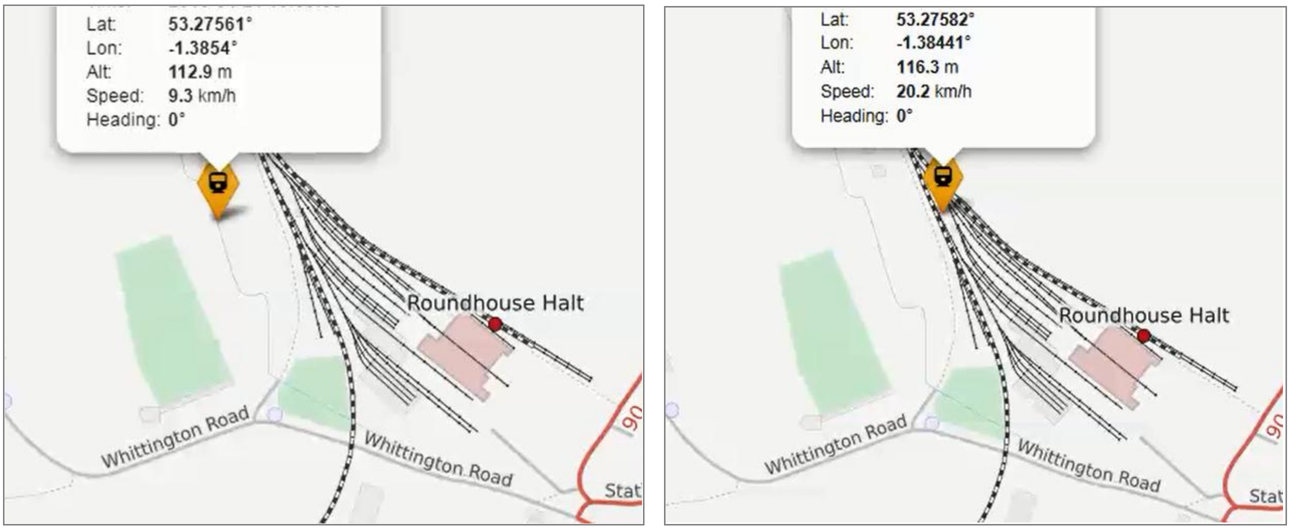

Fig. 4.
Screen shots from the asset tracking portal for visualising the live position data; the left image shows an inaccurate position from an early system configuration, and the right image shows an accurate position

The plot of the position trace recorded for the locomotive with the final system configuration for the sequence of movements along the track on site is presented in **Error! Reference source not found.**, which shows that the position of the locomotive matched very closely the mapped position of the railway tracks it was running on. The lateral positioning error for the locomotive along a portion of the route is shown in the chart in **Error! Reference source not found.**.

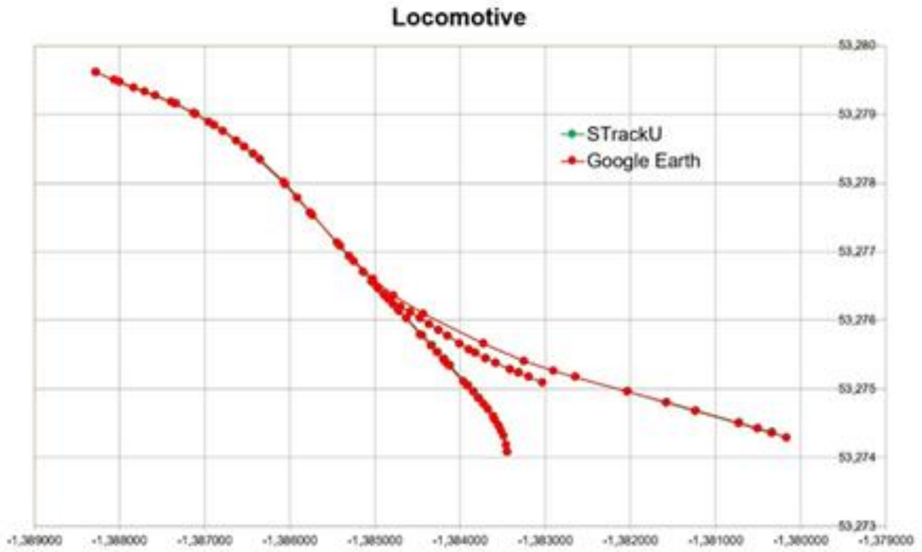

Fig. 5.
Plot of the position trace recorded for the locomotive; maximum length of the trace is approximately 1km

The positioning error statistics for the lateral positions of all of the tracking units, compared to the mapped route of the railway tracks for a complete sequence of movements along the route, are shown in **Error! Reference source not found.**.

It should be noted that the position error and position error statistics shown in **Error! Reference source not found.** and Table 1 respectively, give the accuracy of the positions relative to the route of the rail network traversed during the tests as measured from Google Earth, therefore the results are potentially affected by errors in the coordinates used for the actual position of the railway track. The results show that the accuracy of the positioning data for the final configuration of the system is accurate enough for logistics purposes and are approaching the accuracy required for operational train control. However the assessment of the lateral accuracy of the position data received has been compared to the position of the tracks shown on Google maps satellite imagery. For a more detailed and accurate assessment of the accuracy of the position data, an accurate GPS survey of the actual coordinates of the railway tracks would be required.

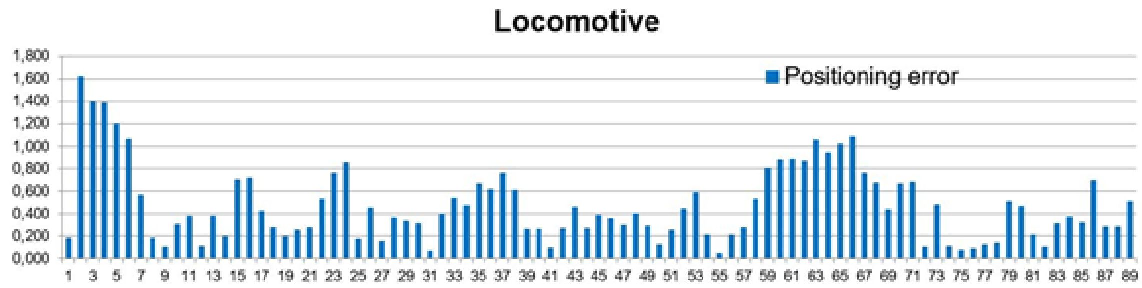

Fig. 6.
Error in the lateral position of the locomotive (measured in mm) during the movement of the train (measured in seconds)

Table 1
Positioning error, deviation from the mapped track centreline

Vehicle	Average (μ)	Standard deviation (σ)	Maximum
Locomotive (L)	0.469m	0.334m	1.263m
Wagon 1 (W1)	1.170m	0.566m	2.864m
Wagon 2 (W2)	1.366m	0.847m	4.196m
Wagon 3 (W3)	1.425m	0.722m	3.446m
Container (C)	0.803m	0.511m	2.009m

4. Conclusions

Installation of a railway vehicle positioning and position communication system was achieved and successfully tested in a full-scale railway environment. After adaption of the system to railway conditions and environmental characteristics, and refinement of the system hardware and software configuration it was shown that the system was able to communicate the position of all of the vehicles in the train to a remote location in near real-time. The accuracy of the positioning data was demonstrated to be sufficient for the overall aims of the project, which is to achieve critical asset tracking for logistical purposes in a variety of applications. However, more accurate reference position of the rail vehicles and tracks would be required to fully assess the accuracy of the positioning system.
The system was installed in conditions representative of an operational railway environment. This indicates that similar results could be expected if the system was applied to a national railway network, although a series of trials would be required to verify this and identify any additional issues. Therefore, the tests showed that the SPARTACUS system is potentially capable of providing real time tracking data for railway vehicles and freight assets in a railway environment, which could be utilised by train operators for logistical purposes and providing rail freight customer's real-time tracking of their goods, allowing them thus to be integrated into their logistics systems.

SESSION 4: INLAND WATERWAYS TRAFFIC AND TRANSPORT RESEARCH

THE RECENT DYNAMICS OF THE NAVIGATION AND MAIN HARBOR OPERATIONS IN THE AREA OF THE MARITIME DANUBE

Carmen Gasparotti[1], Alina Modiga[2], Leonard Domnisoru[3], Eugen Rusu[4]
[1,2,3] *"Dunarea de Jos" Faculty of Naval Architecture, Dunarea de Jos University of Galati, Galati, Romania*
[4] *"Dunarea de Jos" Department of Mechanical Engineering, Dunarea de Jos University of Galati, Galati, Romania*

Abstract: The Rhine-Main-Danube navigation system, known also as the Seventh Pan-European transportation corridor, represents the main inland navigable waterway in Europe that crosses the entire continent and links Sulina at the Black Sea with Rotterdam at the North Sea. Since the river transportation still represents the cheapest way for the commercial traffic, the importance of this waterway is expected to be enhanced in the near future. In this context, the target of the present work is the maritime sector of the Lower Danube, which links the Romanian harbors between Sulina and Braila. This work is mainly focused on the cargo traffic in the low Danube region. The most important ports in this area are Galati, Braila and Tulcea in Romania, Reni and Izmail in Ukraine and Giurgiulesti in the Republic of Moldova. The Romanian Ports on the Maritime Danube, Galati, Braila and Tulcea have a long lasting tradition as inland ports, which offer access to both the Black Sea and the North Sea, through the Rhine-Main-Danube navigation system. The present work gives some relevant insights concerning the navigation and the possible sources of hazards in the maritime sector of the Danube, where usually navigate both sea and river ships.

Keywords: maritime Danube, river traffic, harbor operations, harbor dynamics, navigation risks.

1. Introduction

Danube River is an important waterway that runs over 2400 km from Bavaria to the Danube Delta, passing through eleven countries. It is a part of the Rhine-Main-Danube waterway that links the North Sea and Black Sea, representing the VII Pan-European transportation multimodal corridor, being also a link to other corridors. Danube represents one of the most advantageous transport routes in Romania, due to the low costs and high volume of cargo transported (Rusu, 2010). The development of the VII Pan ‐ European Corridor, Danube ‐ Rhine ‐ Main regions, allows to all the states in Europe a connection with the sea harbors (Zanopol et al, 2014).

An important role for the navigation on the Danube has the Danube-Black Sea Channel. This ensures a direct link between the main harbor of Romania, Constanta, at the Black Sea, and the Danube, thus avoiding the difficult navigation in the Danube Delta. The Danube-Black Sea Channel splits in two. So, the main channel goes to the south towards the harbors Constanta and Agigea and the North Channel reaches the Black Sea at the Midia harbor. The connection of the Danube-Black Sea Channel to Europe's inland network of channels, including Rhine-Main-Danube, reduces the distances between Rotterdam and Constanta, from 6000 km on the old maritime line to 3000 km (Sobaru et al, 1998). The Danube - Black Sea Channel has been designed to facilitate the transit of long convoys, consisting of 6 barges, up to 3000 tons each. The ships up to 5,000 tons, which comply with the maximum dimension of channel, can navigate on the channel (Gasparotti and Rusu, 2014).

Much of the total tonnage of the cargo represents the international traffic. So, the Danube - Black Sea Channel and the Danube River, represents international waterways, which provides to the inland countries access worldwide (Gasparotti et al, 2013). The peak year for the traffic on the Danube-Black Sea Channel was in 2005, during which there were operated over 15 million tons, and also in 2013. The Danube operates 9% of total freight transport in Romania (National Institute of Statistics, 2011), from the total of cargo tons. The maritime sector of the Danube is for the river and sea shipping, extending between Braila and Sulina harbors, with a total of 175 km, from which the Sulina channel has a length of 62.6 km. The Sulina channel has the following ships' maximum dimension: 200 m length, 28 m breadth, 7.32 m draught, and a capacity up to 40,000 dwt. At the entrance of Sulina channel the water depth is restricted to 7-9 m, thus requiring continuous dragging operations to keep the channel open.

The advantages of the river transport compared to other modes of transport, the demand for the development of the link between river and sea harbors has raised the question of finding ways of connecting the Danube River with the sea-harbors in the region (Ivan et al, 2012). The features of the Danube River waterway, the distances between the main harbors in the region and the characteristics of the Danube harbors, are the basis for the implementation of inland and maritime shipping along the Pan-European corridors. The main harbors located on the Danube allow the shipping extension to the Black Sea region, as follows:

- Braila, Galati, Sulina – to Moldavia, South of Ukraine, South of Russia and Georgia,
- Constanta Harbor – to Turkey, Georgia, Greece, and other countries through the ocean,
- River Danube harbors (Giurgiu, Oltenita, Turnu Magurele, Drobeta Turnu Severin) – to Serbia, Bulgaria, Greece, Turkey.

The following waterway sections can be found on the Ukrainian Danube (Figure 1):

- Maritime Danube Reni harbor (km 172) – Black Sea,
- Reni harbor – Izmail harbor,
- Chilia Channel,

[2] Corresponding author: alina.modiga@ugal.ro

- Danube – Black Sea Bystroe Channel.

The Izmail harbor is located on the International Transport Corridor No. 7 (Doubrovsky, 2005). From this perspective, the present work is mainly focused on the cargo traffic in the low Danube region together with the main harbors operations. In order to obtain a complete picture of the river shipping systems that can be used on the Danube - Black Sea and the Danube - Rhine – Main waterways, this work contains the main harbors of the Lower Danube region, harbor operations and the dynamic of harbor traffic.

2. Main harbors in the maritime Danube region and critical navigation conditions

The maritime sector of the Danube starts from Sulina to the Braila harbor, with a minimum depth of the waterway 7.2 m, required by the maritime ships. The maritime Danube includes the Romanian harbors Galati, Braila and Tulcea. The fourth harbor is Giurgiulesti, located at mile 72.2 on the Danube, which operates since the 26-th October 2006.
The Romanian harbors on the maritime Danube have constantly increased their maritime ships traffic. This requires constant dragging operations to keep the Sulina Channel open to the maritime ships (Rusu and Guedes Soares, 2011). Total cargo traffic between Romania and Danube countries is estimated at 20666 million tons per year, of which the river traffic is of 13896 million tons per year.

2.1 Main harbors in the maritime Danube

The harbors located in the maritime Danube region are shown in Figure 1.

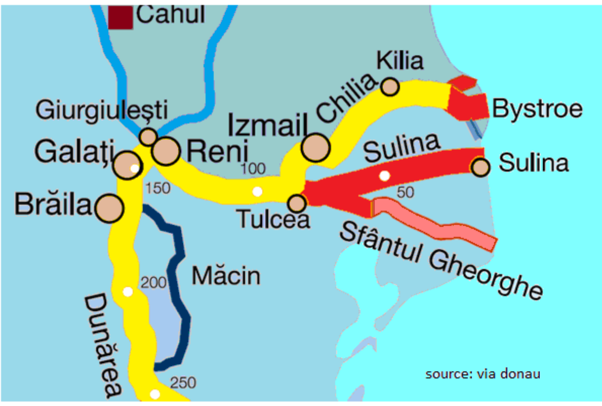

Fig. 1.
The maritime harbors on the lower Danube
Source: (Maritime Danube ports - maritimedays.odessa, 2013)

Galati Harbor Galati Harbor is the largest Danube maritime harbor, located on the left bank of the Danube River, at the eastern border of the European Union with the Republic of Moldova and the Ukraine. Galati is the second largest maritime harbor granting access to the Black Sea, with a rail link to inland countries from the Central Europe (Rusu et al, 2014).
Galati harbor ensures the cargo trans-shipment from barges to maritime ships, for the other Black Sea harbors. The harbor has four terminals: Docks Terminal for general cargo and containers, New Basin Terminal for general cargo, Oil Terminal for oil products and Mineral Terminal. Galati harbor provides the trans-shipment services for all modes of transport and temporary storage, customs clearance, free zone regime, service and ship repairs, services for the collection of waste from ships. There is the only harbor that can operate the direct trans-shipments from the maritime and river ships to the rail system. The technical facilities of Galati harbor include 56 berths, 31 gantry cranes, 10 truck cranes and 9 floating cranes, a forklift and conveyor belts for the transportation of great quantities of coal and iron ore, and also cargo storage on open platforms and closed stores. The surface of the harbor enclosure is of 864131 m^2, from which the open storage area is of 538320 m^2 and the covered storage area is of 7200 m^2. Galati Harbor has two parts: minerals harbor and commercial harbor. The Minerals harbor is operates bulk cargos and also steel rolled products. It has a quay of 1700 m length with 26 shore cranes and 18 shore cranes of 16 t. There are also two conveyors for ore and limestone on the quay. There is an anchorage area at the Minerals harbor at the right side of the Danube River, for maritime ships and barges. The maximum capacity of the ships that can operate in this harbor is of 25000 dwt, with an average depth at quay of about 9 m and the minimum depth of about 7.3 m.
The Commercial harbor is composed from several zones, as follows:

- The old docks, for maritime ships, placed upstream,
- New basin, for maritime ships, placed upstream,
- The ore and steel products zone, for maritime ships,
- The shipyard “damen” galati,

- The road for transit operations,
- The anchorage zone for the maritime ships downstream.

The river traffic of containerized cargo at Galati harbor is underdeveloped, with maximum capacity of 30000 TEU/year and a berthing front for the maritime ships with 136.85 m length. In Galati harbor can operate specialized ships, specialized containerships, semi-containerships, river adapted ships (General Transport Master Plan of Romania - part II, 2014).

Braila Harbor Braila Harbor is a river maritime harbor, situated on the left border of the Danube, between Km 168+300 and Km 170+875. The anchorage zones are established between Km 167 - 168 for the maritime ships and at Km 175 m for river ships. The harbor sectors are the following:

- Old Harbor (Km 169.8 – Km 170.875) has 8 berths which are equipped with floating pontoons, used for passengers, fresh water supply, and general cargo operation with floating cranes.
- Docks Harbor has 496 m of pier on Danube front and 1568 m of pier at basin. The main facilities are grains, silo, bulk and general cargos operations by shore cranes.
- Down river of Docks Basin has a 396 m of pier at Danube water-front for passenger's traffic.

The total surface of the harbor is of 398630 m^2, with an open storage area of 250350 m^2 and a covered storage area of 10804 m^2. Braila harbor has 12 truck cranes (max. 16 t), 8 auto-cranes (max. 25 t), 2 floating cranes (max. 30 t), 5 forklifts, conveyors and pneumatic equipment suitable for handling grain and 25 berths.

Braila harbor has a maximum theoretical capacity of 3.1 million tons per year (General Transport Master Plan of Romania - part II, 2014).

Tulcea Harbor Tulcea is a harbor with 41 berths, of which 5 berths are dedicated to the cargos traffic, 8 gantry cranes (max. 16 t), and a total surface of 82762 m^2 with open storing area of 70000 m^2. The harbor is the gateway to the Danube Delta and has a specific sector for passenger ships. The harbor handles mineral products, quarry extracted, aggregates, gypsum, slag, salt, supplying the materials for the construction sector. The harbor facilities are organized around the quarry extraction and loading materials, open platforms for goods storage waste reception from the ships, maintenance of the ships, harbor equipment's for the ships' operations. Tulcea harbor has not terminals for cereals operations. The Tulcea passenger terminal can handle international and river traffic. At a short distance is also the Tulcea Industrial Harbor for the local metal processing factories. The main activities are the operations of various raw materials: bauxite, iron, ore, lime, ferrous alloys, from the river and maritime ships (General Transport Master Plan of Romania - part II, 2014).

Reni Harbor Reni and Izmail harbors are located close to the Galati harbor, at only 23.5 km and 89.1 km. Reni harbor is located at the borders of Ukraine, Romania and Moldavia. Four transport corridors are intersecting: Europe – Asia, Black Sea and Cretan no. 7 and 9, is being a sea and river harbor. Reni harbor covers 940000 m^2, from which the main operation basin area has 440000 m^2. The water depth in the operation area varies from 2 m up to 25 m. Reni harbor has 6 anchorages points, from which 3 of them are for maritime ships and 3 for barges. Reni commercial sea harbor is a multipurpose transport hub in southern Ukraine. Reni harbor has 30 specialized berths which handle practically with all kinds of cargos, bulk dry and liquid, heavy-weight, containers. The harbor facilities are: 1 bridge crane with a lifting capacity of 250 t, 11 fork-lift trucks, 2 lift truck, 2 bucket loader, 1 harbor tractor, 1 crane Kato, floating cranes. The annual capacity of the harbor is about of 14.5 million t. The berthing line extends to 3927 m with the water depths of about 12 m. The port has specialized terminals for oil handling and ferry. Reni harbor has three specialization cargo areas. First cargo area has a total berthing length of 960 m with an annual capacity of 1 million t, capable to operate ships up to 10000 dwt. The second cargo area has a total length of the berths of 1960 m and an open zone that covers 62737 m^2. The annual capacity average is of 2.5 million t. The maximum operation draught is up to 7 m, for ships up to 20000 dwt. The third cargo area is specialized in handling of bulk cargoes, ore, pellets, coal, iron ore sinter, coke, with annual capacity of 2 million t. The total length of the berths is of 565 m and the open zone that covers 61650 m^2, with ships up to 3000 dwt. The oil harbor is specialized in crude oil and petroleum products with a total berthing line of 258 m, for ships of 20000 dwt. The annual capacity is up to 1.8 million t of oil and petroleum products, and 200000 t of liquefied gas (Reni Sea Port, 2016).

Izmail Harbor Izmail harbor is situated at the Kaliya mouth of the Danube River, at 93 km from the Black Sea, being at the intersection of trade routes between the countries of Central and Northern Europe with those of the Black and Mediterranean Seas. The harbor area is on the Kiliya mouth of the Danube River, from 78 up to 96 km, up to the conventional line of the Ukrainian border on Danube. Izmail harbor can operate ships of maximum 150 m length, width up to 30 m and draught up to 7 m. The harbor has modern facilities and equipment for operation of bulk cargo, and containers. The harbor has 24 berths with depths from 3.5 m to 7.5 m, with three cargo terminals, 8 warehouses with a total area of 19700 m^2, 3 floating Ganz cranes (16 t) and 100 truck lifts (1.5 - 25 t). There are also 6 automobile and caterpillar cranes of 6.3- 50 t capacity. The open cargo storage area is of 201100 m^2, with 53 gantry cranes (40 t). The first terminal has 8 berths, operating packed cargoes, equipment, agricultural machines, metals, and grains. The total operation capacity is 1.2 million t per year. The second terminal has 4 berths, operating bulk cargos and containers. The operation capacity is up to 5.4 million t per year. The third terminal has 7 berths, operating bulk and general cargos (Izmail Sea Port, 2016).

Giurgiulesti Harbor Giurgiulesti harbor has river-sea operations, located at the 133 km on the Danube, being the only Republic of Moldova harbor. The harbor has intermodal facilities for containers operations and terminals for oil products, grains and passenger transport. The terminal for oil products has one berth, an oil base with 8 reservoirs for

63000 m^3 storage of petroleum products, operation capacity of over one million tons per year and facilities for railway cisterns handling. The grain terminal has a storage capacity of 50000 tons and the operation capacity of 3000 tons per day, for ships up to 7000 dwt. The vegetable oil terminal has a storage capacity of 6000 tons, for ships up to 10000 dwt. The bulk terminal is located on the banks of the Prut and has an area of 40000 m^2, for petroleum coke, crushed stone and quarry products. The container and general cargo terminal has an open storage area of 20000 m^2, with cranes with maximum lifting capacity of 70 t (Giurgiulesti International Free Port, 2016).

2.2. Auxiliary harbors and related activities

Besides the activities directly related to the shipping, as cargo loading-discharging, stowage-lashing, storage on platforms, in the harbors there are also a series of auxiliary activities (National Company the Administration of Maritime Danube Ports, 2016). The auxiliary harbor activities include:

- Maintenance of the technical characteristics of the water transport infrastructure,
- Land and floating navigation signals,
- Maintenance dredging to ensure the navigation depths in harbors and waterways,
- Collecting the residuals, wastewater and garbage from ships,
- Salvage and refloating of the ships.

The related activities for harbors as support for the main activities are:

- Cargo traffic monitoring in the harbor, issuing the cargo shipping operations database,
- Approval of the studies and projects for the development of water transport infrastructure,
- Establishing of the fees for the harbor service,
- Development of the it harbor services.

2.3. Issues identified in harbors

The analysis on short and long term of the activities and the facilities of the maritime-river harbors on the Danube from Romania have revealed some issues that are affecting the efficiency of the harbor activity: old or undeveloped infrastructure, poor connectivity, the inability to operate new cargo types, lack of intermodal functionality, capacity deficit (Table 1) (General Transport Master Plan of Romania - part II, 2014).

Table 1
Identified problems in Romanian harbors on the lower Danube

Harbor	Identified problems				
	Old or undeveloped infrastructure	Poor connectivity	Inability to operate new cargo types	Lack of intermodal functionality	Capacity deficit
Tulcea		x	x		x
Galati	x	x	x	x	x
Braila	x	x			

Source: (General Transport Master Plan of Romania - part II, 2014)

Galati harbor has an old infrastructure in some parts over 50 years. In addition, this infrastructure was designed for the requirements of Galati steel industry, which in the last decade has significant decreased. The harbor has a poor connectivity, which combined with the old infrastructure, cannot have a proper bulk cargo and palletized cargo terminals. This will allow increasing the operation capacity of modern cargo types and the harbor international integration (Gaparotti, 2009).
Braila harbor has an old infrastructure, with outdated berths and bad connections with other transport ways. The harbor modernization will allow the increase of the cargo capacity operation.
Tulcea harbor has a reduced capacity of operating the cereals, so that the general cargo terminal must be upgraded grain handling. This will increase the harbor capacity and new cargos operation.

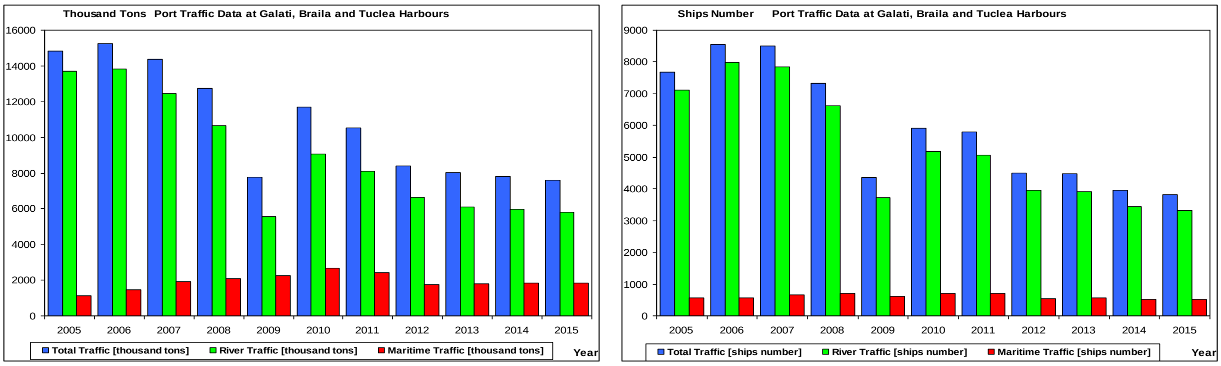
2.4. Critical conditions for navigation

The navigation on the maritime Danube has several difficulties due to unfavorable meteorological and hydrological conditions. From the meteorological point of view, the winds have a dominant influence, with high intensity in autumn and winter, generating often storms. In March the haze occurs, cloudiness increases, with drizzle and even sudden decrease of the temperature down to -10^0 C (Gasparotti and Rusu, 2012). From the hydrological point of view, the difficulties of navigation are determined by the presence in some areas of the Danube of a narrow waterway, restrictions due to, riverbed deposition of silt, strong currents and pronounced curves with small radius of the waterway. The traffic is most difficult in the Tulcea elbow, at the entrance of Sulina channel, but also in other parts of the maritime Danube.

Due to the environmental conditions for the ships' safety there are imposed several navigation restrictions (Gasparotti et al, 2014).

3. Dynamics of the cargo traffic in the main harbors

The traffic system in the Danube maritime harbors is a part of the European traffic system, ensuring the link of Romania to other European countries (Omer, 2015). The cargo traffic in the three sea-river harbors, Galati, Braila and Tulcea, is shown in Figure 2.



a b

Fig. 2.
Port traffic data at Galati, Braila and Tulcea harbors, a-thousand tons and b-ships number
Source: (National Company the Administration of Maritime Danube Ports, 2016)

From Figure 2 results that the traffic through these harbors has declined continuously over the last decade, 2005-2015, particularly in 2009, only 40.5% compared to 2005. Some increase has been recorded in 2010-2011 and after the traffic has been reduced to similar level of 2009. The significant reduction of the marine traffic in the Danube harbors is due to the financial and economic crisis that has also involved Romanian starting 2008. The river traffic share in the total cargo transport is higher than the maritime one. The cargo traffic with river ships is going on the entire length of the Rhine-Main-Danube Channels, from Sulina to Rotterdam. The cargo traffic with maritime ships is going on from Sulina (km 0) to the Braila harbor (km 175). Galati, Braila and Tulcea harbors have a diversified cargo traffic, being composed of raw materials products (career and gravel, gypsum, clay, salt), ferrous and non-ferrous ores, rolled, cereals, food, tobacco, timber, construction materials, oil, solid fuels (coal, coke) (General Transport Master Plan of Romania - part II, 2014). In 2011 the main types of cargos operated in the three harbors were: iron and ores for Galati, cereals for Braila and ores for Tulcea (fig. 3).

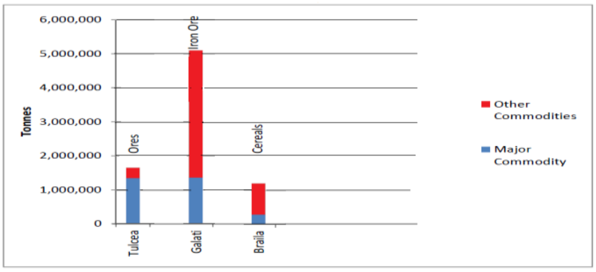


Fig. 3.
Tonnes handled by Romania's maritime harbors from the Danube in 2011
Source: (*General Transport Master Plan of Romania - part II, 2014*)

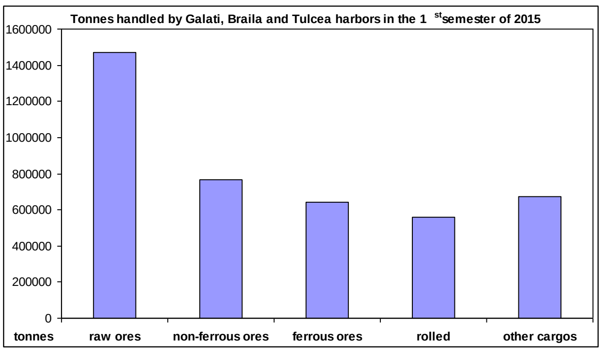

Fig. 4.
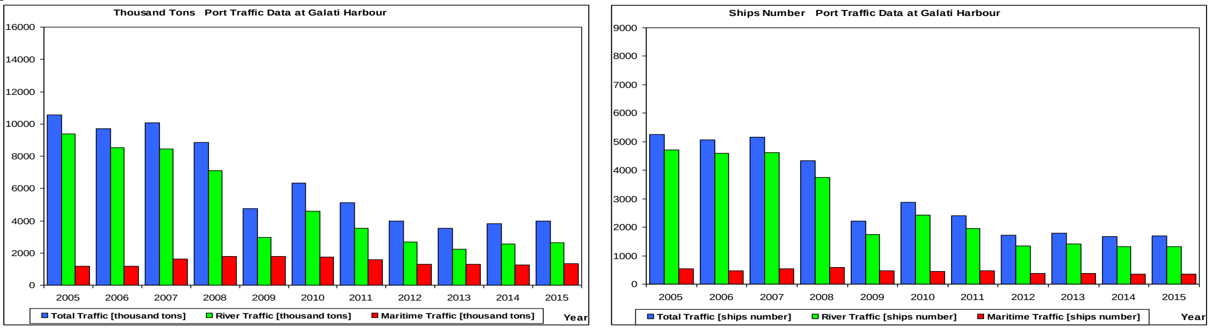
Tonnes of cargo handled by Galati, Braila and Tulcea harbors in the first semester of 2015
Source: (*General Transport Master Plan of Romania - part II, 2014*)

In the first half of 2015, the total traffic by groups of cargos reveals that mineral products gross (career, gravel, gypsum, clay, salt) were in the largest amount followed by non-ferrous ores, iron ore and rolled (fig. 4). In the Galati harbor (fig. 5) the total and inland traffic has a down-trend, reaching the minimum in 2009 and then, after a slight increase in 2010-2011, decreases to values under 2009 reaching 37.65% for the total traffic and 27.9% for river traffic taking as reference year 2005.



a b

Fig. 5.
Port traffic data at Galati harbor, a-thousand tons and b-ships number
Source: (National Company the Administration of Maritime Danube Ports, 2016)

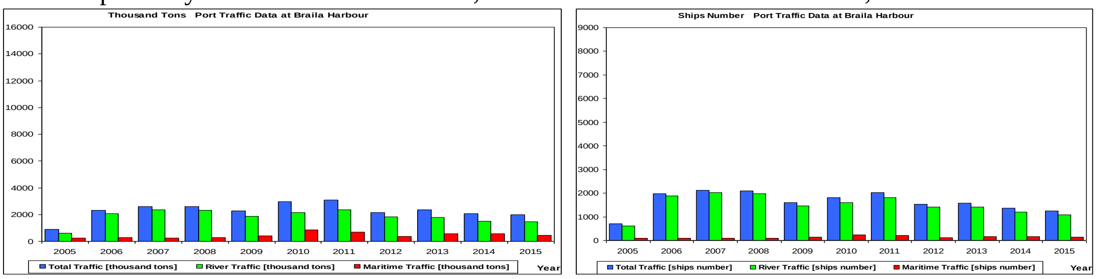
The maritime traffic has had an up-trend in the period 2005-2009, when it has increased by 54.8% in 2009 taking as reference year 2005, and after 2009 it has had a down-trend, in 2009 the traffic being higher by 37.7%, and in 2011 by 21.9% taking as reference year 2015. The number of ships operating in Galati harbor has continuously decreased for both river and the maritime traffic. The major part of the traffic share represents the bulk cargo (iron ore, coal, cereals, scrap metal, building materials), the general and standardized cargos traffic being very reduced. The decrease of the traffic in the Galati harbor is mainly due to the decrease of the coal and steel handled for the local steel industry that is in decline. The recorded operations in Galati harbor in 2011 and the forecasted one for 2020 and 2030 are presented in Table 2.

Table 2
The recorded and forecasted operations in Galati harbor having as reference year 2005

Terminal	**2011**	**Forecasted**	
		2020	**2030**
General cargos	41.83%	45.39%	49.49%
Bulk cargos	100.79%	109.37%	119.26%
Containers	-	-	-
Petroleum products	-	-	-
Cereals	30.21%	32.78%	35.74%
Cement	-	-	
Coal	7.22%	7.84%	8.54%
Steel	-	-	-
Other	0.96%	1.90%	2.62%

Source: (General Transport Master Plan of Romania - part II, 2014)

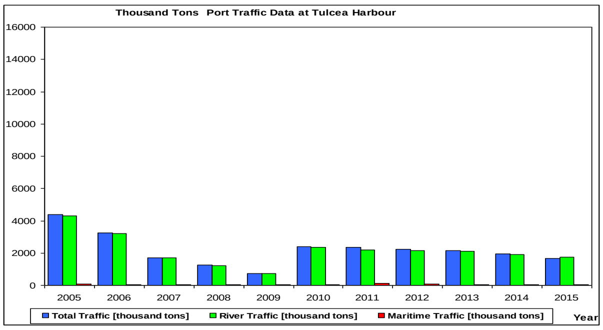
Table 2 shows that the bulk cargo terminal operates at full capacity, the general goods operates at almost half capacity, the cereals terminal operates at a third capacity, while the other terminals operate at a very small volumes and the prognosis keeps this trend. The cargo traffic at the Braila harbor (figure 6) had an up-trend in 2005-2011, for both river and maritime traffic as tonnage and number of ships, reaching a maximum for the total and the river tonnage in 2011, of 251% respectively 281% referenced to 2005, and for the maritime traffic in 2010, of 232% referenced to 2005.



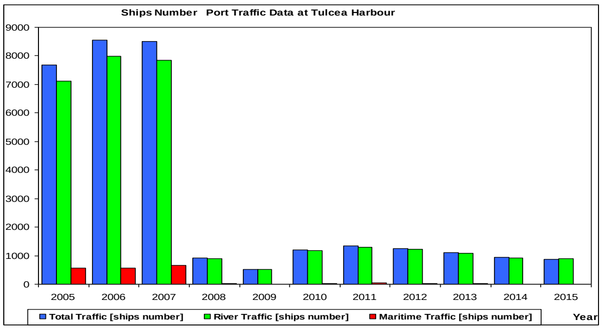
a b

Fig. 6.
Port traffic data at braila harbor, a-thousand tons and b-ships number
Source: (National Company the Administration of Maritime Danube Ports, 2016)

The main cargos traffic in the Braila harbor is mineral products, wood products and chemical fertilizers. In Tulcea harbor, the cargo traffic is lower than in Galati and Braila harbors. There was a down-trend in 2005-2015 (figure 7), the minimum value being reached in 2009, of 16.85% referenced to 2005, and after that there was recorded a significant increase, especially in 2010-2013, both as tonnage and the number of ships.



a



b

Fig. 7.
Port traffic data at Tulcea harbor a-thousand tons and b-ships number
Source: (National Company the Administration of Maritime Danube Ports, Galati, 2016)

The recorded operations in Tulcea harbor in 2011 and the forecasted one for 2020 and 2030 are presented in Table 3.

Table 3
The recorded and forecasted operations in Tulcea harbor having as reference year 2005

Terminal	2011	Forecasted	
		2020	2030
General cargos	7,97%	11,00%	11,36%
Bulk cargos	100,60%	117,47%	113,69%
Containers	-	-	-
Petroleum products	-	-	-
Cereals	1,53%	1,79%	1,73%
Cement	-	-	-
Coal	-	-	-
Steel	-	-	-
Other	-	-	-

Source: (General Transport Master Plan of Romania - part II, 2014)

Table 3 shows that in 2011 the terminal for bulk cargo has been used at full capacity and for 2020 and 2030 is forecasted a growing demand over the available capacity. The general cargos and cereals terminals had a reduced activity and is forecasted to keep this trend (General Transport Master Plan of Romania - part II, 2014).

4. Conclusions

Danube River is an important waterway of Europe, being part of the Rhine-Main-Danube multimodal transportation corridor that links Sulina, at the Black Sea, with Rotterdam, at the North Sea. The maritime Danube presents a number of restrictions due to the unfavorable meteorological and hydrological conditions as wind, fog, variable water depth and breadth, strong currents strong, tight curves.

The maritime-river harbors in the Lower Danube zone are: Galati, Braila and Tulcea from Romania, Reni and Izmail from Ukraine and Giurgiulesti from the Republic of Moldova. As the present work shows, it is necessary to develop consistent investment projects for the modernization of the harbors infrastructure and of specialized terminals, in order to increase the operational capacity, new cargos to be handled and their integration into the international cargos traffic.

The cargo traffic in Galati and Tulcea harbors had a down-trend in 2005-2015. On the other hand, in Braila harbor both river and maritime cargo traffic had an up-trend in the same period. The recorded operations are maximum for bulk cargos, relatively low for the general cargos and cereals and very low for other type of cargos in the Galati harbor. In the case of Tulcea harbor the recorded operations are maximum for bulk cargos and very low for the cereals and general cargos.

Finally, it has to be highlighted that the volume of cargos traffic at the river-maritime Danube harbors has important values, those harbors playing a significant role for the European transport. Moreover, in the future it is possible to develop this cargo traffic and the quality of services by proper investments into the harbor facilities.

Abstract: As compared to seagoing ships the influence of the aerodynamic loads on the river ships has to be taken into account in a different manner due to the possible instant modification of both speed and wind direction. The evaluations of the hydro-aerodynamic loads for a range of ship speeds, heading angles and wind speeds and their effects have been carried out for two types of river ships: a Port Container 156 TEU and a Chemical Tanker of 5300 m^3. Based on the calculations, comparative numerical examples are presented.

Keywords: ship resistance, wind forces and moments, maneuverability of river ships, aerodynamic resistance.

1. Introduction

The possible instant modification of both speed and wind direction could lead to important effects on ship hydro-aerodynamic resistance and course keeping ability taking into account the appearances of different rapid combinations between ship speed, wind direction and speed as well as ship heading. The effects of such combination are even more evident when different restrictions like shallow water, limited breadth of channels, geometry of river courses, limitation of ship speed, etc., are taken into account. Voluntary speed reductions have to be also considered in order to avoid dangerous effects.
The evaluations are carried out for 4 wind speeds (10 m/s, 15 m/s, 20 m/s and 25 m/s) and a rage of heading angles between 0° (fore wind) and 180° (aft wind) with a step of 10°. For all combinations, the wind forces in x and y direction as well as the yaw moments are calculated using the method suggested by Isherwood. Based on the results obtained for the two different ships considered in the present study, some important conclusions have been formulated. It has to be underlined that, during the preliminary design stages, such kinds of evaluations are not very often considered and serious problems could arise during navigation. A customized evaluation has to be based on the specific information related to the characteristics of the inland navigation areas. The evaluations of the hydro-aerodynamic loads for a range of ship speeds, heading angles and wind speeds and their effects have been carried out for two types of river ships: a Port Container 156 TEU and a Chemical Tanker of 5300 m^3. In order to be able to evaluate the influences of the above mentioned parameters, the selected ships have similar main dimensions, similar frontal projected areas above waterline but, the lateral profile areas above waterline are significantly different the ratio being about 1/3. The main characteristics of the two ships are presented in Table 1 and Table 2.

Table 1
Main characteristics of the Chemical Tanker (ChT)

Main characteristics	**Full scale**

Ship speed, v	20 Km/h / 5.56 m/s

2. Evaluation of hydrodynamic and aerodynamic forces and moments

As a first step the resistance was calculated for a range of advance speeds without taking into account the influence of the wind speed and direction. Additionally, in order to be able to evaluate the speed losses due to the wind acting in x direction, a number of 4 wind speeds have been considered. By taking into account the wind direction relative to the ship, polar diagrams have been draw up, allowing the possibility to evaluate the total resistance in any direction. The wind direction has been taken into account in a range between 0° and 180° with a step of 10°. Consequently, the evaluation of the lateral forces and yaw moments has been also performed based on the calculations of the wind coefficients according to Ysherwood method.

2.1. Calculation of hydrodynamic and aerodynamic longitudinal forces

For both ships the evaluation of the resistance has been performed using Holtrop – Mennen (Holtrop at all, 1982) method for a range of speeds specific for each ship. It has to be mentioned that the results do not take into account the river water flow which is depending on the location and, moreover, can be easily considered in the calculations. The aerodynamic components of the resistances due to ship speeds are included in the evaluations. The comparative results for the two ships, the Port Container (PC) and the Chemical Tanker (ChT) are presented in Fig. 1. Mention should be made that the Chemical tanker is equipped with classical rudder configuration while the Port Container has a steering nozzle system.

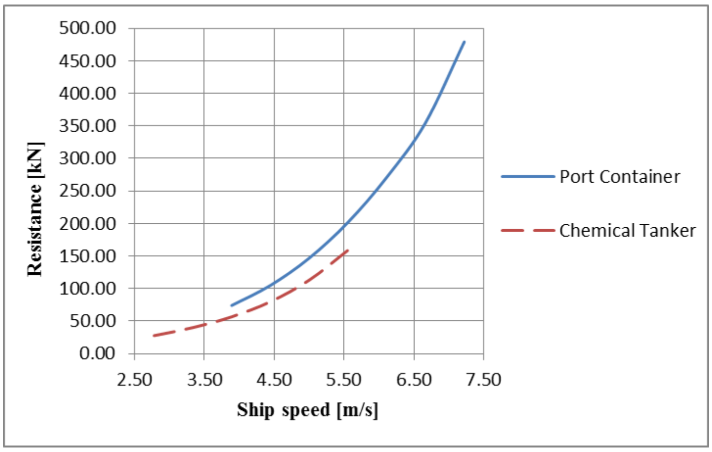

Fig. 1.
Comparative results of resistances for the two ships

The results of the calculations related to the speed loss of the ship due to wind action in x direction (fore wind) are shown in Fig. 2 and Fig. 3.

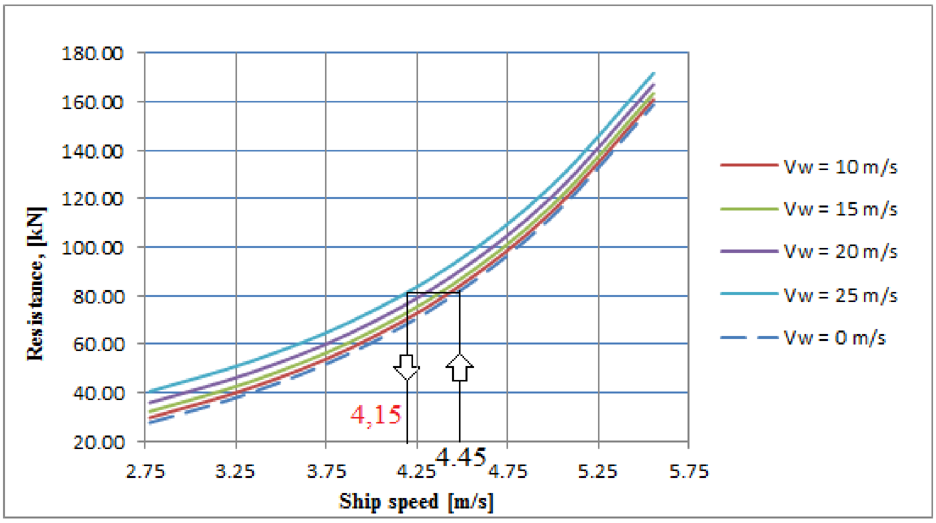

Fig. 2.
Speed losses due to wind action for the Chemical Tanker case

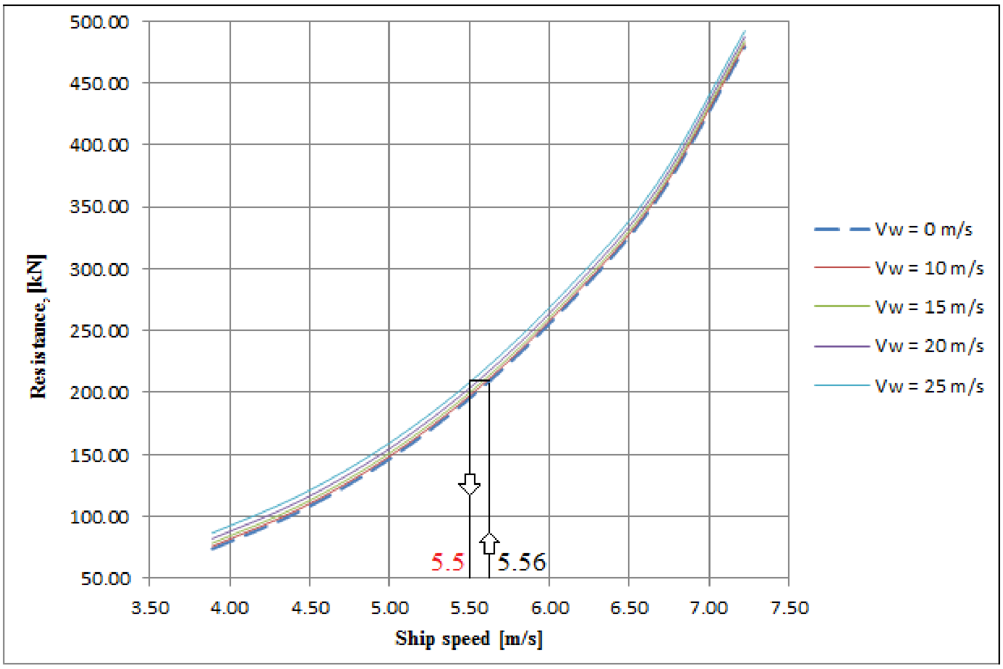

Fig. 3.
Speed losses due to wind action for the Port Container case

It can be seen that the speed losses due to frontal wind action are practically negligible. For the largest wind speed used for calculations, 25 m/s, the speed loss is only about 0.3 m/s (1.1 km/h) for the Chemical Tanker and 0.06 m/s (0.22 km/h) for the Port Container, respectively. Similar diagrams have been made for the effective power as a function of ship speed and wind speed being possible to evaluate the necessary additional power required to keep a constant speed for a given ship speed and a certain wind speed in the investigated range. As previously mentioned, the calculations of the wind forces have been made based on the evaluation of aerodynamic coefficients according to the method suggested by Isherwood (Isherwood, 1982). The aerodynamic coefficients in longitudinal direction C_X as function of wind direction are calculated using formulas resulting from regression analysis of a large amount of experimental tests. As a matter of fact, the best solution would be the direct evaluation of the aerodynamic coefficients based on wind tunnel tests (Crudu, 2015) when the real exposed areas can be modeled and tested. In this case experimental facilities are required. The big advantage is that some other useful tests can be carried out, cheaper than the hydrodynamic ones, like preliminary analysis and optimization of hull forms.

The influence of wind direction on the total resistance of ship can be represented using polar diagrams which are giving a global overview. The results obtained for both ships are presented below in Fig. 4 for the Chemical Tanker and Fig. 5 for the Port Container.

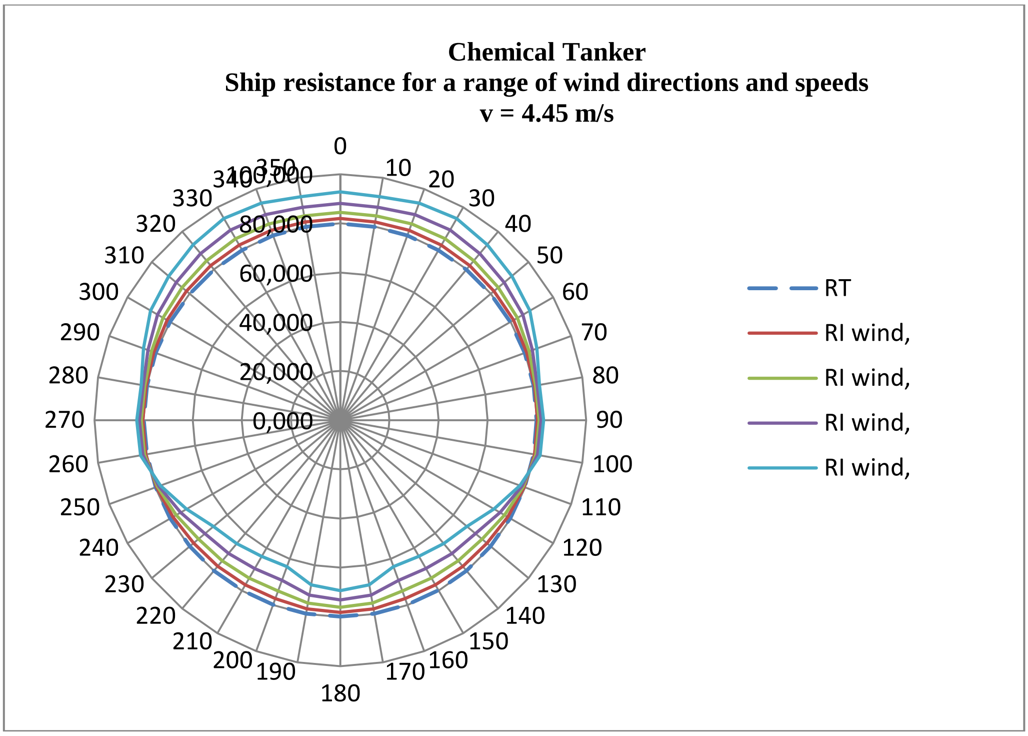

Fig. 4.
Polar diagram of ship resistance for the Chemical Tanker

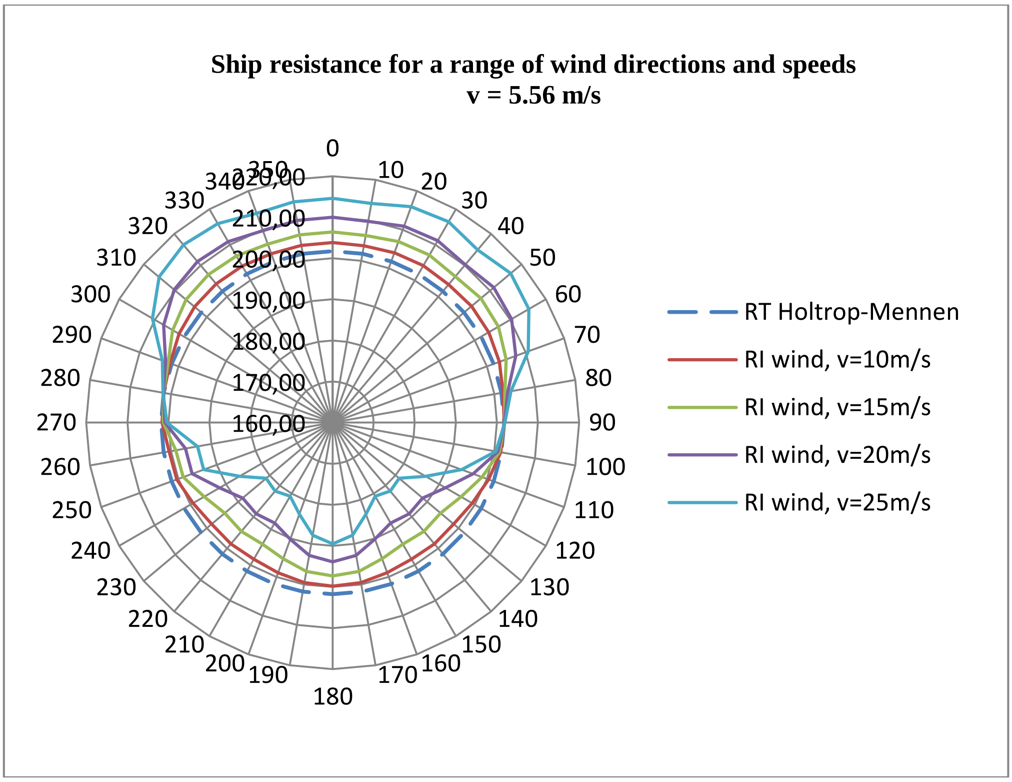

Fig. 5.
Polar diagram of ship resistance for the Port Container

2.2. Evaluation of aerodynamic lateral forces and yaw moments

The evaluation of lateral forces and yaw moments is performed using the above mentioned procedure. This time the coefficients in transversal direction C_Y and the yaw coefficients, C_N, are calculated using specific given formulas. The graphical representations are in Fig. 6 and Fig. 7 for C_Y coefficients and in Fig. 8 and Fig. 9 for the C_N ones, together with the polynomial approximations. These approximations, in fact mathematical formulations, could be very useful in order to solve the equations of equilibrium under the wind excitation forces and moments.

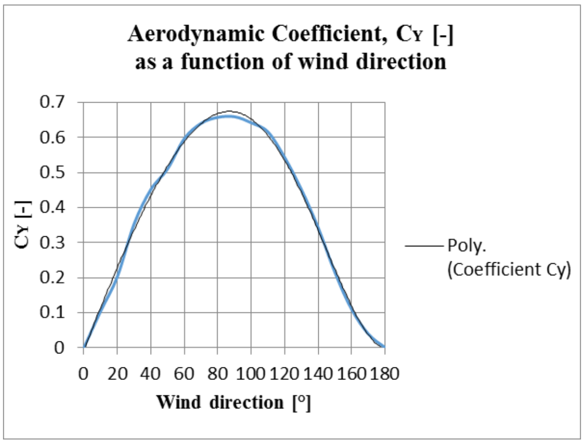

Fig. 6.
Aerodynamic lateral coefficient – Chemical Tanker

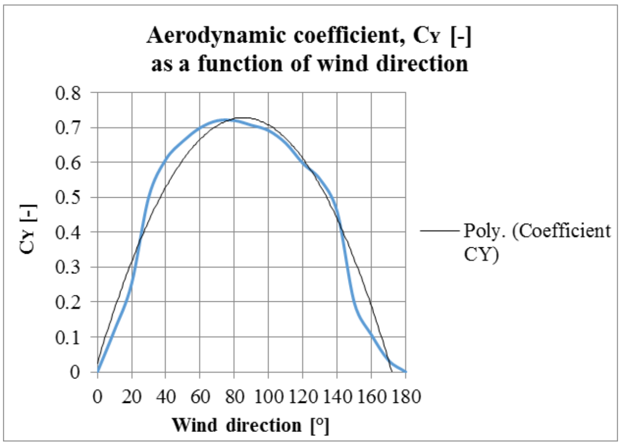

Fig. 7.
Aerodynamic lateral coefficient – Port Container

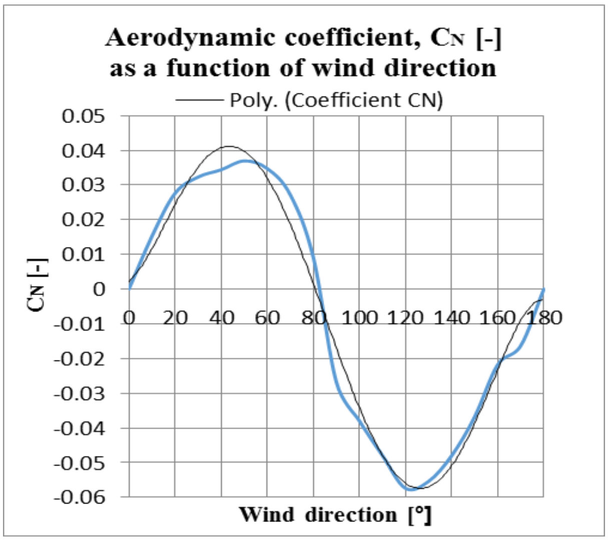

Fig. 8.
Aerodynamic lateral coefficient – Chemical Tanker

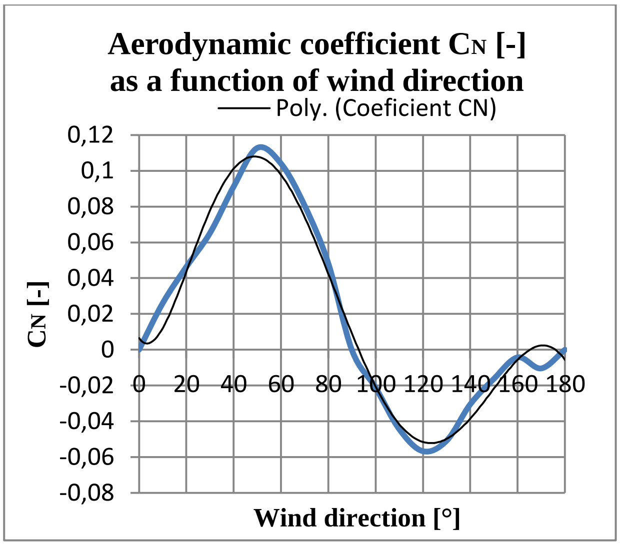

Fig. 9.
Aerodynamic lateral coefficient – Port Container

Using the aerodynamic coefficients it is now possible to calculate the aerodynamic forces and moments which have to be compensated by the bow thruster and the rudder (the case of the Chemical Tanker) or by the bow thruster and the steering nozzle system (the case of the Port Container). Between the main elements which have to be taken into account in order to be able to define the most suitable solution in the preliminary design stages are:
- The aft part configuration of the body and the propulsion configuration both influencing the rudder geometry and its hydrodynamic characteristics;
- The opportunity to use a steering nozzle propulsion system which is also depending on the aft geometry influenced by the engine room arrangement;
- The geometry and performances of the bow thruster which are influenced by the fore geometry and the draft which has to be adapted in order to navigate in restricted waters. This will strongly influence the diameter of the bow thruster.

According to the above mentioned observations, the following active elements have been evaluated in order to identify the forces and moments necessary to counteract and to keep the ship in safe condition:

- For both ships, based on the information provided by the body plan and the general arrangement, the performances of the bow thrusters have been calculated for a range of diameters using computer codes developed in the research department of the Faculty of Naval Architecture (Obreja at all, 2015) . Then, the lateral forces, Y_0 and the yaw moments, N_0, related to the pivoting point defined as aft amidships with 1/6 L_{PP}, became available.
- For the Chemical Tanker hydrodynamic calculations have been performed, using the above mentioned package of applications, for a rudder having a NACA 0015 profile and then the lateral forces Y_R, and moments N_R, were available.
- Based on powering calculations, using the in house computer code already mentioned, it became possible to evaluate the lateral forces Y_P and N_P.

In Fig. 10 are presented the dependency of the lateral forces on wind speed and direction for the Chemical Tanker. The horizontal lines represent the total lateral forces provided by the bow thruster for 3 different diameters added by turn to the maximum force provided by the rudder. It can be observed that the lateral aerodynamic force corresponding to a wind speed of 25 m/s can be compensated if a diameter of 1.2 m can be used.

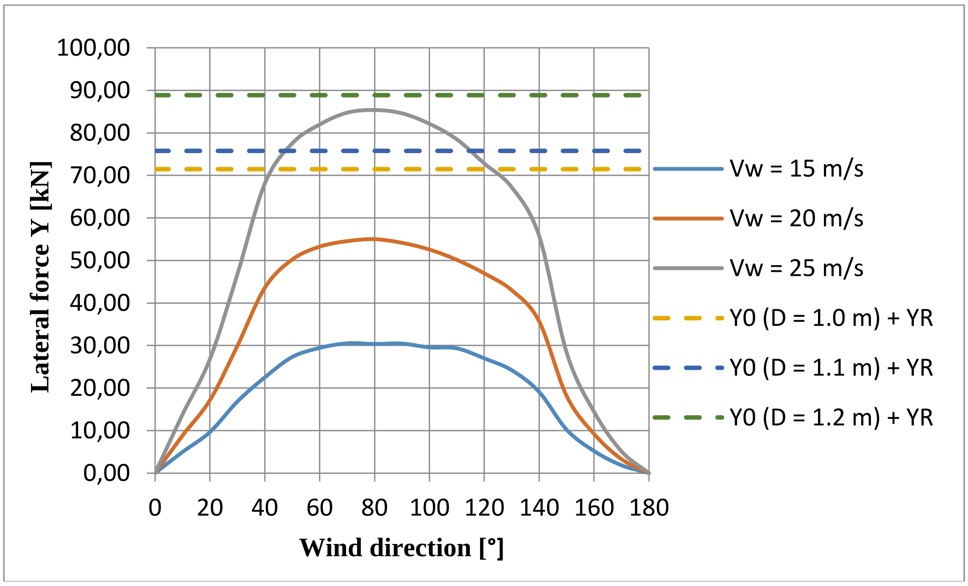

Fig. 10.
Chemical Tanker - Wind lateral forces for 3 speeds and available compensation forces generated by the bow thruster and the rudder

A similar situation has been identified for the Port Container. This case is presented in Fig. 11. Unfortunately, larger diameters of the bow thrusters can't be afforded due to the limitation of the draft if navigation case with empty containers is considered and the draft could reach low values in the range of 1.5 m. Consequently, higher lateral wind speeds than 22 m/s cannot be compensated and have to be stated in appropriate documents for the ship master.

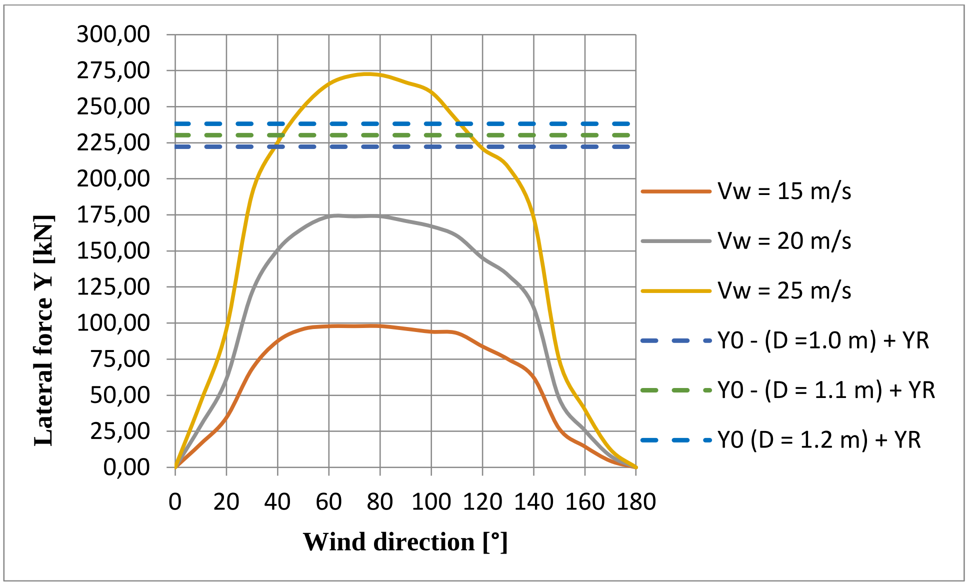

Fig. 11.
Port Container - Wind lateral forces for 3 speeds and available compensation forces generated by the bow thruster and the rudder

It has to be noticed the significantly higher values for the Port Container case due to the about three times higher value of the lateral projected area.
Similar calculations have been performed in order to evaluate the aerodynamic yaw moments due to wind and the total compensating yaw moments provided by the rudder (ChT), bow thrusters and the propulsion system (PC). It has to be underlined that all moments have been calculated using as reference to pivoting point, commonly used in maneuverability calculations and simulations. The results are presented in Fig. 12 for the Chemical Tanker case and in Fig. 13 for the Port Container one. The Fig. 12 is clearly showing that the aerodynamic moments can be compensated using only the moment created by the rudder for a deflection angle of 25°. The moments due to the bow thruster are not

represented and, in fact, are not necessary in order to compensate the wind yaw moments. Mention should be made that the moments generated by the bow thruster are much larger the ones generated by the rudder. However, the reason to have a bow thruster on board is mainly dictated by the necessity to have good maneuverability performances at low speeds of the ship in restricted waters. Consequently, minimum diameter of the bow thruster can be considered.

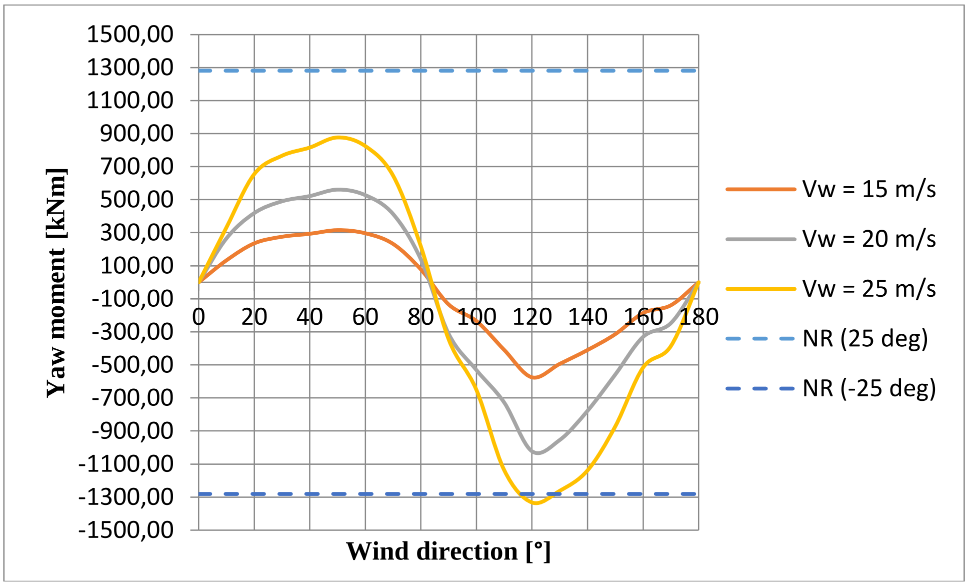

Fig. 12.
Chemical Tanker – wind yaw moments and the rudder moment, N_R

The case of the Port Container is presented in Fig. 13. The minimum moment, necessary to compensate the wind moments, can result from the combination of the moments given by the bow thruster corresponding to its minimum diameter, D = 0.9 m and the moment created by the propulsion system for a deflection angle of 25°. A larger diameter of the bow thruster and a larger deflection angle of the steering nozzles will lead to much larger moments.

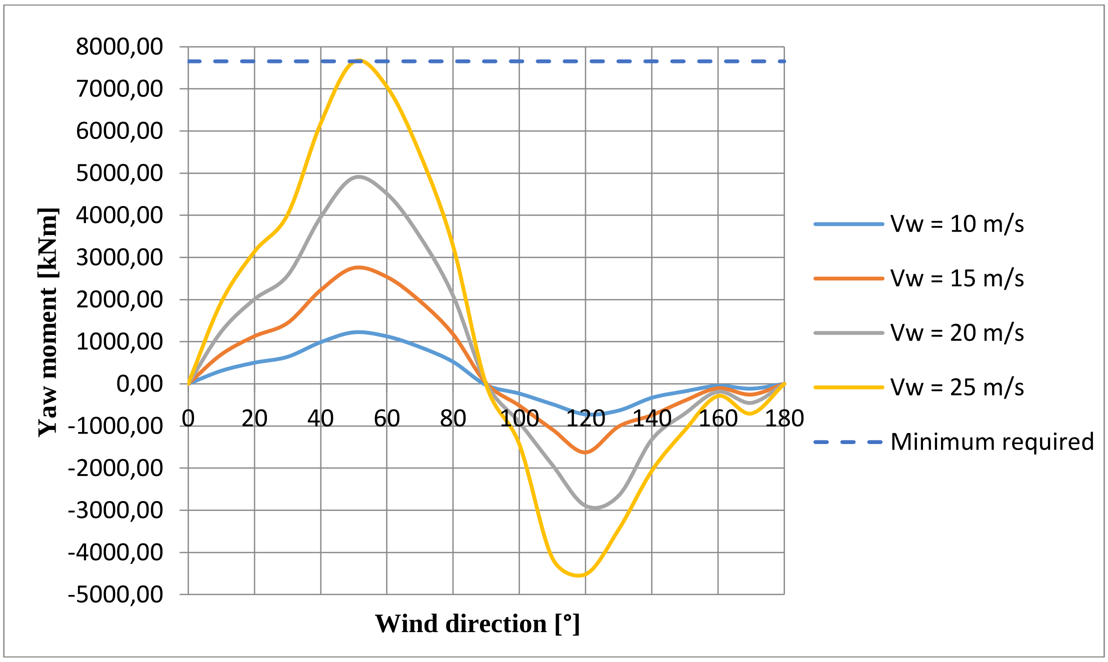

Fig. 13.
Port Container – wind yaw moments and the minimum required moment

In order to better identify the influences of the lateral and frontal projected areas synthetic diagrams are presented below for both ships. The Fig. 14 refers to the lateral wind forces, Y_W, while the Fig. 15 is dealing with the aerodynamic yaw moments, N_W.

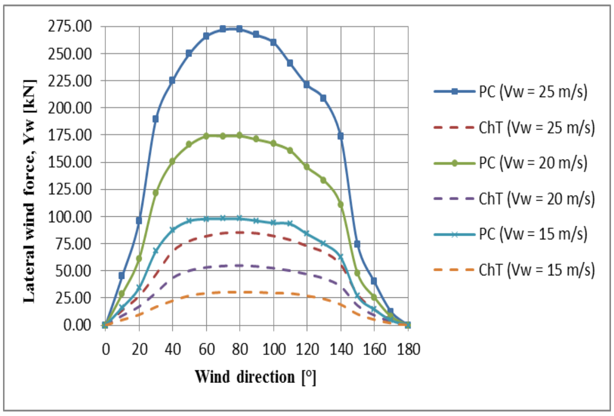

Fig. 14.
Comparative aerodynamic lateral forces, Y_W, as function of wind speed and direction

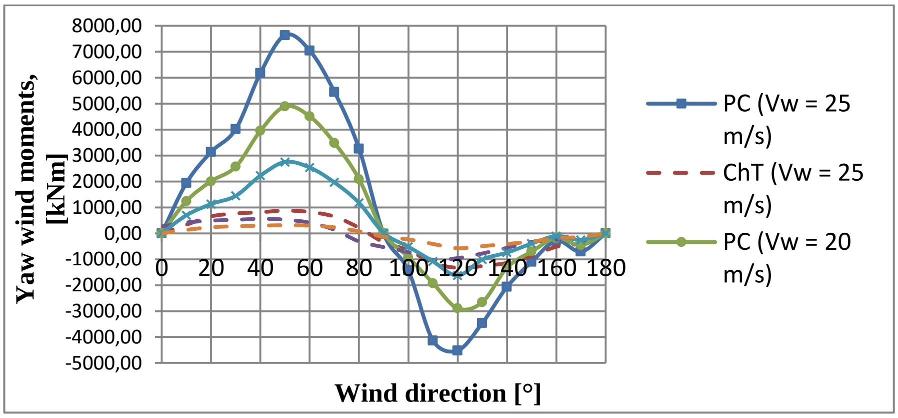

Fig. 15.
Comparative aerodynamic yaw moments, N_W, as function of wind speed and direction

Generally, as already mentioned, the procedure to be used in order to find the most appropriate solutions is based on the equations of equilibrium.
- On one side it has to be defined and calculated wind forces and moments which have to be compensated, Y_W and N_W.
- On the other side it is necessary to perform the evaluation of the forces and the moments provided by the steering system, Y_R and N_R in case of rudder and/or Y_P and N_P in case a steering nozzle propulsion system is considered and also the forces Y_0 and moments N_0 generated by the bow thrusters.

If all these parameters can be mathematically defined, as shown in Fig. 6 to Fig. 9 for the aerodynamic coefficients, then a system of equations can be built having as possible variables, depending on the matter in focus:
- The bow thruster diameter speed of rotation or power absorption, etc.;
- The type of rudder to be used (Bosoanca et all, 2013), the geometric characteristics of the rudder, etc.;
- The characteristics of the propulsion system.

In Fig. 16 and Fig. 17 there are given two examples regarding the possibility to formulate a mathematical description of the dependence of the bow thruster forces, Y_0 and moments, N_0, on the diameter using polynomial functions. The example is for the bow thruster design for the Chemical Tanker. A similar example can be developed for the Port Container case.

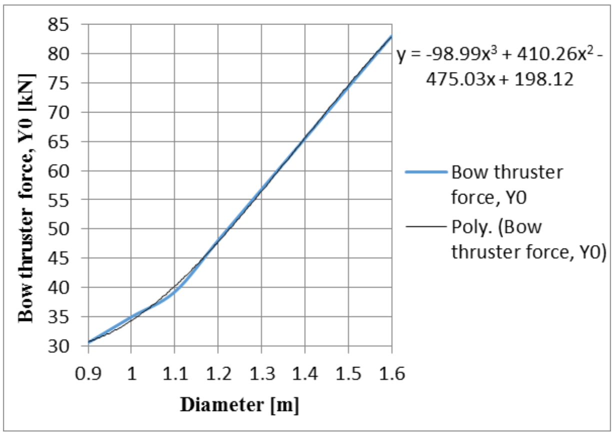

Fig. 16.
Bow thruster forces, Y_0, as function of diameter (Chemical Tanker)

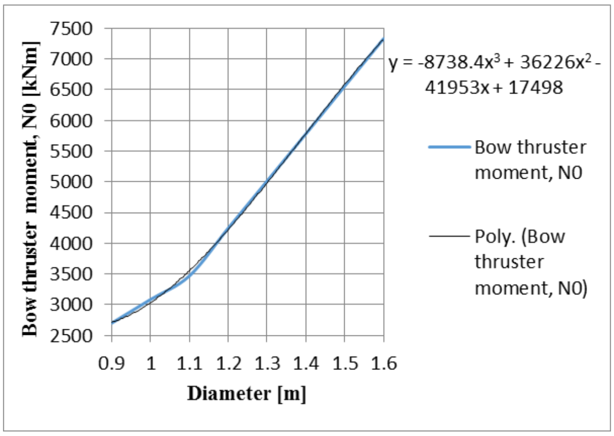

Fig. 17.
Bow thruster moments, N_0, as a function of diameter (Chemical Tanker)

In Fig. 18 and Fig. 19, which are presented having in mind the evaluation of the effectiveness of the two steering systems, are displayed the moments created by the rudder for the Chemical Tanker and the steering nozzle system used for the Port Container. In both cases the results are defined related to the pivoting point. It has to be noticed the much higher moments generated by the steering nozzle as compared to those provided by the classical rudder configuration. That is why, in order to counteract the high aerodynamic forces and moments, the steering nozzle system was chosen. These results have to be correlated to the information provided by Fig. 12 and Fig. 13. The simple linear dependency of the moments generated by steering nozzle system against the nozzle deflection angle could lead to simplified models which can be used at least during the preliminary design stages.

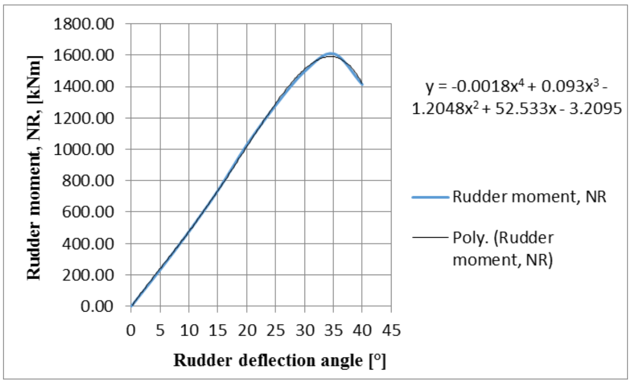

Fig. 18.
Rudder moments, N_R, as function of deflection angle (Chemical Tanker)

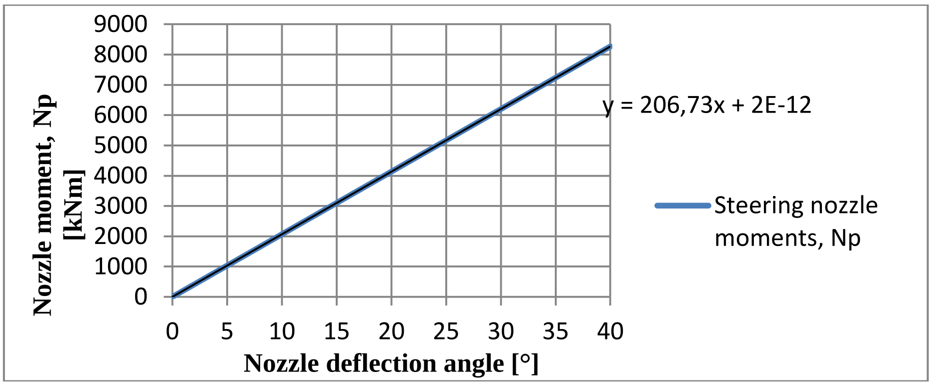

Fig. 19.
Steering nozzle moments, N_P, as a function of deflection angle (Port Container)

3. Conclusions

The evaluation of aerodynamic forces and moments has been performed using the method developed by Ysherwood because of the relatively simple formulas based on statistics which are not dedicated to river ships. Consequently,

different other more suitable methods could be used if such systematic investigations exist. However, the best ways to perform such kind of calculations have to be based on aerodynamic tests, using dedicated facilities like wind tunnels.
It was clearly shown that speed losses due to aerodynamic forces do not play an important role in case of river ships. On the contrary, the aerodynamic lateral forces and moments could play a decisive role depending on the navigation areas. Unfortunately, such kinds of estimations are carried out very seldom, the main concern being only related to the stability criteria, mainly required by the classification societies.
The results presented in this paper are not taking into account the river water flow speed downstream or upstream. It refers only to still water case but, if systematic information related to the navigation areas exists, these can be easily taken into consideration for computations.
All moments are expressed considering the pivoting point, commonly used in maneuverability applications.
The steering nozzle system is much more effective as compared to the rudder arrangement (Crudu, at all, 1988), the generating lateral forces and moments having much higher values. Moreover, the maneuverability qualities are significantly increased from the point of view of zig – zag maneuvers which are very important in case of inland navigation as compared to course keeping stability.
The evaluations of some maneuverability characteristic have been evaluated for both ships. The results, which are not presented in the present paper, are proving that the stability on route, evaluated by the calculation of linear stability coefficient, is according to the standards. Moreover, the turning ability of the ship is determined on the basis of turning circle characteristics and it fulfills the IMO criteria.
During the next design stages, using CFD applications or hydrodynamic tests using Planar Motion Mechanism (PMM), the hydrodynamic derivatives can be evaluated (Obreja at all, 2010), and a more general mathematical model can be developed and customized according to the required application.
The aerodynamic forces and moments are also important when large convoys of barges are pushed in canals mainly in open areas. It is commonly happening to lose the control due to strong winds or wind gusts which could suddenly appear. Such configurations do not have specially design means to be able to counteract the forces and moments generated by the wind. A relatively simple solution is to use a detachable module, having incorporated a bow thruster which can be remotely controlled, placed in front of the convoy. For ecological reasons, electric engines powered also using alternatively a set of electric of batteries can be also used. Another solution which was used in the past consists in connecting the pusher to the convoy using hydraulic cylinder, the pusher being now able to act itself like a rudder for the convoy. In principle, in both cases, the same procedures like those exposed in the present paper can be successfully used.

Acknowledgements

The authors would like to express their gratitude and thanks to NASDIS Consulting SRL, Galati, Romania, for the continuous support offered in developing relevant research activities and providing valuable information which plays an important role in developing reliable practical applications.

THE DANUBE RIVER FLOW ANALYSIS IN CRITICAL POINTS OF THE FAIRWAY

Gabriel Popescu[1], Leonard Domnisoru[2], Mihaela Amoraritei[3], Alina Modiga[4]
[1,2,3,4] *"Dunarea de Jos" University of Galati, Faculty of Naval Architecture, Galati, Romania*

Abstract: An ongoing concern for all companies that manage fairways of rivers is to ensure conditions for navigation all year round even in the periods of low water levels. The long experience and the results of statistical analyses developed by the A.F.D.J. (Lower Danube River Administration) company have revealed a set of critical points on the fairway of the Danube River in Romanian sector. Critical points are those parts or zones of the fairway, in the periods of dry weather, when water levels are very low, so that the Danube drafts restrictions occur for ships navigation. This paper includes the analyses of the river flow at critical points in order to identify the medium and long-term solutions that will ensure smooth river traffic, based on a partnership between the "Dunarea de Jos" University of Galati and the A.F.D.J. The study method used is the numerical analysis C.F.D. (Computational Fluid Domain). The 3D modeling of the fairway at critical points was achieved by C.A.D. software, based on the bathymetric measurements. The 3D models were imported in a general C.F.D. software application for the analysis of the critical Danube flow points. The C.F.D. analysis results are presented as the flow lines of the analyzed fluid. Based on the results obtained by C.F.D. analysis, there can be identified the main causes that defines a point on the fairway of the Danube to be considered as a critical one.

Keywords: Danube, fairway, 3D modeling, computational fluid domain, fluid flow critical points.

1. Introduction

In Romania the maintenance activities, by providing optimal conditions for navigation on the Danube fairway, are made by the Lower Danube River Administration A.F.D.J. This company continuously monitors the depth of the fairway by bathymetric measurements. Where depths are less than the values of safety (7.30 m) the dredging works are carried out.
The management of the fairway on the Romanian Danube river sector has led to the identification of zones where the frequency of dredging works is higher. Deposition of the sediments recorded after a dredging process is much higher in those zones. Zones with this feature are called critical points of the fairway.
The study of those zones and the identification of the main causes that lead to the formation of critical points is a necessity. The results of this study can identify the correct zone selected for the dredging operations.

2. Problem formulation

One of the critical point is at the downstream Galati, near the 73 nautical mile, known as the Prut zone (Figure 1). In order to identify the causes that make the Prut zone a critical point (Figure 1), the Danube flow will be analyzed by C.F.D. approach. This numerical study will return the flow lines, velocity and pressures distributions. The analyses of these parameters will enable the formulation of the possible causes of sediments deposition at the Prut critical point.
The flow lines obtained by C.F.D. can be interpreted as directly related to the geometry of the fairway. The speed distributions by CFD study will contribute to the analysis of sediment deposits process. The pressure distributions in the fairway can lead to the formulation of possible causes that make the Prut zone a critical point.

3. Computer method

In this study, the C.F.D. analyses of the flow in the critical Danube river zone are done by the XFlow module of the SolidWorks program. This module allows: geometry modeling in fluid domain, fluid characteristics selection, C.F.D. analysis, inlet and outlet boundary conditions, post-processing of the numerical results.
The computer method has the following steps:
Step 1 . Based on data from satellite and bathymetric measurements, the 3D geometry of the zone examined is created. The 3D numerical model is developed by SolidWorks software, with solid elements, using the 3D Face extrude function (Figure 2). The bottom details were generated by the free-form options implemented in the modeling program (Figure 3 & Figure 4).

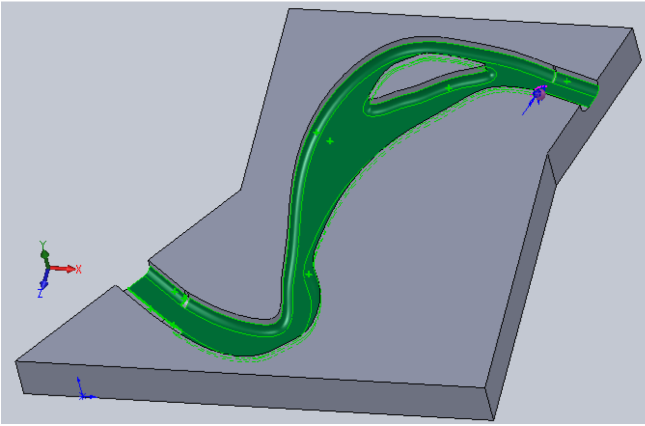

Fig. 2.
3D model for the Prut zone

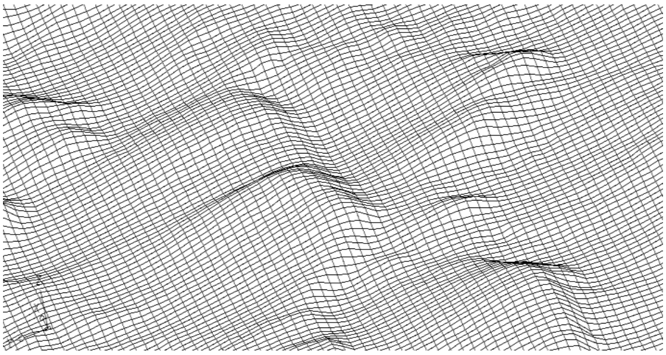

Fig. 3.
3D face for the bottom details
Source: (A.F.D.J. 3D Face export .dxf)

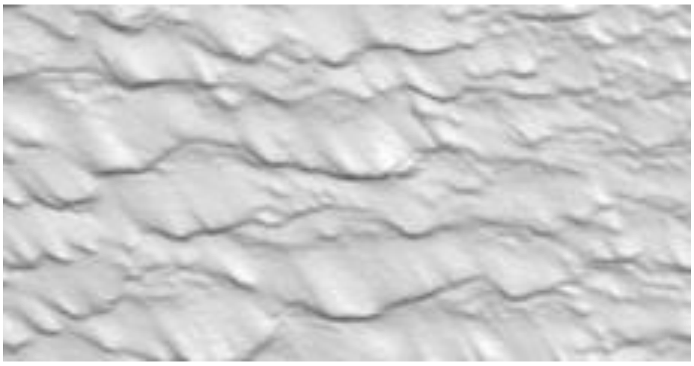

Fig. 4.
3D model for the bottom details
Source: (A.F.D.J. rendered 3D Face)

Step 2. The 3D modeling of the inlet and outlet is made at the input and output sections of the model generated in step1. See figure 5, where I is the inlet surface and O is the outlet surface.

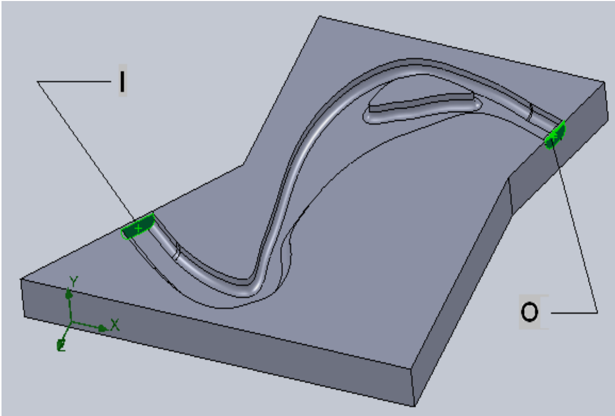

Fig. 5.
3D models for the input and output sections

Step 3. The 3D components generated in steps 1 and 2 are assembled in one numerical model.
Step 4. The parameters for the CFD numerical analysis are defined. At the inlet condition the flow speed is defined. The flow speed is variable over the water domain, being influenced by size, slope roughness of the riverbed. In the water domain the flow velocity increases from the sides towards the middle and from the bottom to the surface of the water channel. The vertical flow velocity is function to the water depth and the presence of obstacles in the riverbed. The outlet condition was defined using the known flow at the exit of the water domain.
Step 5. The numerical model is checked and the C.F.D. analysis is carried on.

4. Numerical results

The CFD numerical analysis results are:

- Distribution of the pressure. Figure 6 shows zones with maximum pressure. The pressure on the banks of the riverbed, in the A zone, is influenced by the particles dislocation and inclusion into the flow,

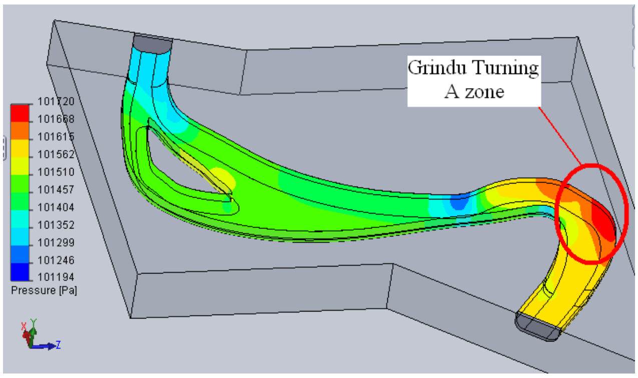

Fig. 6.
The distribution of pressure

- Distribution of flow lines. Figure 7 shows the influence of the Grindu elbow and the northern island from the analyzed zone,

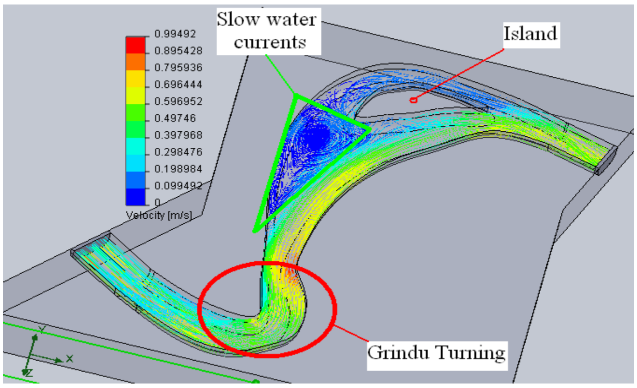

Fig. 7.
The distribution of flow lines

- Charts of speed distributions in different river bed sections (Figure 8).

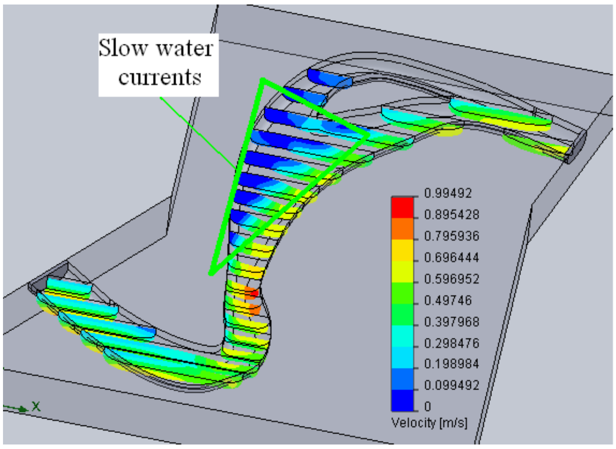

Fig. 8.
Speed charts in different riverbed sections

5. Discussions

Particles dislocation and inclusion into the flow at the river elbow from Grindu turning zone must be analyzed in connection with the results for the distribution of flow lines in Figure 7 and speeds in Figure 8. The velocities decrease in the slow water current zone, influenced by sedimentation, deposition of solid particles taken from the Grindu turning zone. In order to validate the numerical model, the analysis results (Figure 7 & Figure 8) are compared with the bathymetric measurements done in January 2016 (Figure 9) and the flow lines distribution at the end of March 2016 (Figure 10).

Fig. 9.
The bathymetric measurements done in January 2016
Source: (AFDJ Galati)

Fig. 10.
The bathymetric measurements at the end of March 2016
Source: (AFDJ Galati)

It results that the slow water current in Figure 7 and Figure 8 corresponds with declared critical zone (red rectangles) from Figure 9 and Figure 10. It means that the zone where flow rates decreased significantly (green triangle) overlaps with decreasing depth fairway zone by depositing silt particles.
Observation:
The maps of the bathymetric measurements in Figure 9 and Figure 10 contain only the depths for the width of the fairway, taken from the total Danube riverbed.
The map of depths, measured between the ends of March 2016 compared to the January 2016, reveals a significant difference. The particle deposits rates are higher in March over a wider zone of the fairway compared to January.
This study is included in to a macro analysis of the Danube riverbed geometry, focused on the Prut critical zone, and represents the first stage of an ongoing complex analysis.

6. Conclusions

After the analysis of the critical zone Prut from the Danube River, there results that the main cause for the phenomena of sediment deposition and fairway depth decrease is the macro geometry of the Danube elbow. The Grindu zone, placed at the right side of the Danube elbow is subjected to high pressures that lead to dislocation and particle transport. The solid particles are deposited where the river speed is significantly reduced.
The numerical results of this study, based on the macro geometry of the Prut critical zone, makes possible to identify a first solution in reducing the rate of particles dislocation by an efficient alluvial defense through clothing the left bank zone A (Figure 6).

NUMERICAL SIMULATION OF A CARGO PLANING BOAT WITH INVERTED KEEL

Adrian Caramatescu[1], **Florin Pacuraru**[2], **Catalin Cristea**[3]
[1,2,3] *"Dunarea de Jos" University of Galati, Naval Architecture Faculty, Galati, Romania*

Abstract: The present study concerns the numerical simulation of the free surface flow around the hull of a composites power boat used for cargo shipping on the Danube River. The flow around planing hulls is complex since it involves different physical phenomena such as thin spray flow, wave breaking, air trapping and turbulent boundary layer. The RANSE VOF solver computation method is employed to evaluate the flow field in planing condition and to estimate the powering requirement. The numerical simulation results are compared to the Savitsky semi empirical method.

Keywords: numerical simulation, composites hull, RANSE VOF, fast inland cargo.

1. Introduction

The cargo boat appeared as a necessity to transport supplies to the remote and isolated Danube Delta villages. The Danube Delta Biosphere Reservation regulations forbid the construction of paved road in the pristine environment therefore the only available mean of transportation remains on the waterways. Additionally, the waterways offer a complete network of channels and river branches deserving all the villages and settlements in the Danube Delta. Each year, a few hundred thousand tourists visit this natural reserve, and this raises the necessity to supply the all the touristic resorts with food and beverages, within the shortest amount of time possible, due to the perishability of the supplies, therefore the boat should be on planning regime and equipped with refrigeration devices. There have been considered the following project prerequisites: composites construction for lightweight hull and maximum loading capacity, with a reasonable powering installed; sterndrive propulsion system with diesel inboard, because of the shallow draught advantage, steering, cooling and exhaust system integration into the assembly, tilting system that allows propeller cleaning if it gets clogged with vegetation and reduction of effective draught; 3.5 tons of cargo capacity, loaded on the deck and into 2 refrigeration units; open deck with lightweight textile covering for minimization of the total weight of the boat; trailerable size for road-worthy transport without special permits.

The resulting design of the cargo boat was an all-composite construction developed using available register scantling rules. The hull has a particular shape, with a wide inverted keel extended in the centerline from aft to fore, resulting in a semitunnel or false catamaran shaped hull. The advantages pursued by this particular shape are a reduction of the draught and the reduction of the resistance by trapping a layer of air inside the semitunnel, thus reducing the friction of the hull in that area. There have also been considered one pair of spray rails and the chine was reversed in order to direct flow along the hull and create additional lift by retaining pressure on the bottom. The main dimensions and form coefficients of the hull are given in Table 1. Figure 2 shows the body plan of the hull. The general arrangement consists in a small open aft cabin for the crew of 2, open deck used as cargo area, refrigeration units area and engine room.

Table 1
Main dimensions and form coefficients of the hull

Dimension	Value
Length overall	9.35 m
Hull length	8.50 m
Waterline length	6.76 m
Block coefficient	0.80
Deadrise angle	12º
Waterplane area	15.71 m
LCF	3.11 m
Wetted surface	18.60 m
LCG	3.00 m
VCG	0.29 m
Beam	2.80 m
Depth	1.10 m
Maximal Draught	0.36 m
Unloaded displacement	2.50 t
Loaded displacement	5.80 t
Payload	3.50 t
Fuel	0.20 t
Crew	2 persons
Navigation range	Danube, zones 3 & 4

Rendered view of the hull design

The availability of the robust commercial Computational Fluid Dynamics (CFD hereafter) software and high speed computing has led to increasing use of CFD for solution of fluid engineering problems across industry and boat building is no exception. CFD based design tools can provide a solution to boat design problems but it requires powerful flow solvers which are able to take into account realistic geometries as well as complex physical phenomena, such as free surface, spray and planing. Accuracy requires careful attention to the physical modeling, particularly to the effects of turbulence, and to the numerical discretization. The difficulty that characterizes the resistance prediction of planing hull is that both viscous and pressure components are related in a non-linear way to the dynamic lift force and trim moment developed by the complex flow on the hull at high speeds. Moreover, the complex multiphase flow associated with high Froude number flows and the development of the spray sheet increase the complexity of the numerical simulation.

During the last decades, several numerical studies on planing hulls have been performed based on the potential flow theory Ghassemi and Ghiasi (2008), Battistin and Iafrati (2003), but their drawback is that they are only valid in the very high speed range and they are not able to capture the steep waves and spray sheets. However, as the computer power steadily increases and better models have been developed to eliminate the drawbacks of potential approach, the hydrodynamic performance and planning behavior are numerically predicted by solving the RANS equations and six degrees of freedom equation, the free surface is simulated by VOF method, Yumin et al (2012), Azcueta (2003), Caponnetto (2001).

This work has focused not only on predicting the hydrodynamic forces and moments, but also the complex multiphase free surface flow field generated by planing boat with inverted keel monohull at high Froude numbers. Volume of fluid (VOF) approach allows the capturing of breaking waves around a ship, including both plunging and spilling breaking waves, the formation of spray, and the entrapment of air.

2. Computational Strategy

A general numerical method to predict planing behavior of a boat is presented in the paper. The NUMECA/FineMarine commercial code is used to compute the flow solution on a multiblock, high-performance parallel computing fashion. The RANS solver is fully implicit, based on finite volume method to build the spatial discretization of the transport equations. The velocity field is obtained from the momentum conservation equations and the pressure field is extracted from the mass conservation constraint, or continuity equation, transformed into a pressure-equation. In the case of turbulent flows, additional transport equations for modeled variables are discretized and solved using the same principles Deng et al (2010), Duvigneau et al (2003). The *k*-ω turbulence model is used for turbulence closure in this paper. Free-surface flow is simulated with a multi-phase flow approach. Incompressible and nonmiscible flow phases are modeled through the use of conservation equations for each volume fraction of phase/fluid Queutey and Visonneau (2007). Velocity-pressure coupling is handled with a SIMPLE like approach. Ship free motion can be simulated with a 6 DOF module. Some degree of freedom can be fixed as well. An analytical weighting mesh deformation approach is employed when free-body motion is simulated. Considering that equilibrium position at high Froude numbers is significantly different from the hydrostatic position, one can expect large mesh deformation. In some case this deformation may leads to negative cells. For practical reasons, the approach employed in this paper splits the problem in two parts: estimation of the hull position for the specific speed and the flow computation around the hull estimated position. In order to start the computation directly from a specific speed, an estimation of the final hull position is necessary. Estimation of the final position may be found from an assumption of the semi-empirical method, a potential code computation or an initial CFD computation. The information targeted are the dynamic trim and sink. In the present work, the Savitsky (1964) semi-empirical method has been employed. For this computation, particular attention will be paid to the previously mentioned problems such as free surface capturing, numerical stability, computation time.
For complex geometries such as a planning boat hull, the grid generation is a very complicated task to accomplish. A Cartesian mono-block unstructured grid of about 2.5 million cells has been generated to cover the entire computational domain along the bare hull. The grid topology is an H-H type. Taking into consideration that planning hulls usually have a very long and narrow wake field, the domain size has to be extended in order to capture the wake correctly. Since the wake development is particularly interesting for planning hull designers, a proper wake field capturing is the key of the computation. The domain covers one ship length upstream of the bow, half above, one and a half ship length out from the side and bottom of the hull, and four ship length downstream of the stern. A noslip boundary condition was enforced at the hull surface, where the first grid point from the body surface was located at around y+=30 for turbulence modeling considerations. A grid refinement has been performed in the stern wake area, on the spray rails and on the free surface as it can be seen in Figure 3. The refinement is cell-based: existing cells are subdivided into smaller cells to locally create a finer grid. Layers of high aspect ratio cells tangentially to the wall have been inserted in order to correctly resolve boundary layers. The technique is based on successive subdivisions of the cells connected to the walls, Wackers and Visonneau (2009).

Grid refinement

3. Results and Discussion

The present paper introduces a numerical procedure to analyze the free surface flow around a planning boat with inverted keel. The hull form used for analyses have been designed using Rhinoceros and Orca3D plugin commercial software. The hull form has been exported from Rhinoceros to Hexpress in order set up the computational domain, to generate the mesh and to set up the boundary conditions. Finally, the grid has been exported to Fine Marine commercial CFD software which is used for parallel computations
A hull has a planning behavior when the hydrodynamic forces play a dominant role in carrying the boat weight while the buoyancy force is less significant. The hydrodynamic pressure lifts the vessel and also affects the trim angle.

Depending upon Froude number (hereafter Fn), three states of navigation can be identified: displacement state, for Fn<0.4, transition (semi-planning) for 0.4<Fn<1 and planning for Fn>1-1.2. An usual value of the Fn which marks the transition region from non-planning to planning conditions is Fn = 1.0, but other values are used in the literature since the phenomenon has no strict definition, Faltinsen (2006). Increasing the boat speed form zero, the hull passes through different phases from initial hydrostatic condition to the final planning condition. In the first phase, the moving hull begins to create the own horseshoe wave in front of the hull, that travels with the same speed as the body. If the moving body continues to accelerate the stationary horseshoe wave begins to travel with a speed that is slightly smaller than the hull speed, thus leading the hull to begin to climb on the stationary wave also known as hump. The progressive climbing on the hump leads to a modification of the trim angle, also increasing the hull resistance. In the aft part of the boat, the flow for high-speed corresponding to Fn higher than 0.4, separate from the transom stern creating a hollow downstream the transom, that travels with the hull. The experiments shown that an increase of the hollow extension with the Froude number, but on the other hand the hollow width is not particularly affected by the speed, Faltinsen (2006). During this transition phase, particular hull design characteristics as bottom strakes and inverted bilge help increasing the pressure on the bottom panels and separate flow on the sideboards, for reduction of the frictional resistance. This transition phase presents the maximum bare hull resistance. The transition phase ends when the hump moves towards the aft section of the hull. Once the hump passes aft the center of gravity of the boat, the trim angle begins to decrease and the hull resistance decreases too. During this planning state (phase) only a part of the bottom of the hull is wetted and the flow presents multiple turbulences, many induced by the strakes (spray rails) present on the bottom that helps to create a flow separation.

The paper proposes a numerical investigation for solving the viscous free-surface flow based on RANS-VOF method. A series of seven simulations have been carried out for a range of Froude numbers from 0.66 to 1.31, in order to investigate de flow around a boat in semi-planning and planning conditions and also to estimate the power requirements to reach the planning. As long as, in the semi-planning and planning conditions the hydrodynamic pressure lifts the boat and also affects the trim angle, the simulations have been perform considering solved free sinkage and trim for different imposed speeds. One of the most challenging task is to capture the development of very complex flow phenomena as overturning and spray. Simulation performed revealed that in bow area an overturning phenomenon occurs in incipient phase of semi-planning at Fn=0.66, as shown in Figure 4. Spray rails have been used on the hull bottom to increase the lift force by bending the water spray downwards. In order to separate the flow along the sides reversed chine has been considered. The effect of spray rails and reversed hard chine on flow detachment at Fn=0.99 is depicted in Figure 5. Furthermore, in the stern region, water separates from the hull at the transom edge for semi-planning and planning conditions, as one can see in the Figures 6, 7 and 8 and as it was expected, a hollow downstream the transom develops. The hollow modifies its shape and volume dynamically in direct correlation with the speed of the hull, being reduced in depth and increased in length as the speed increases.

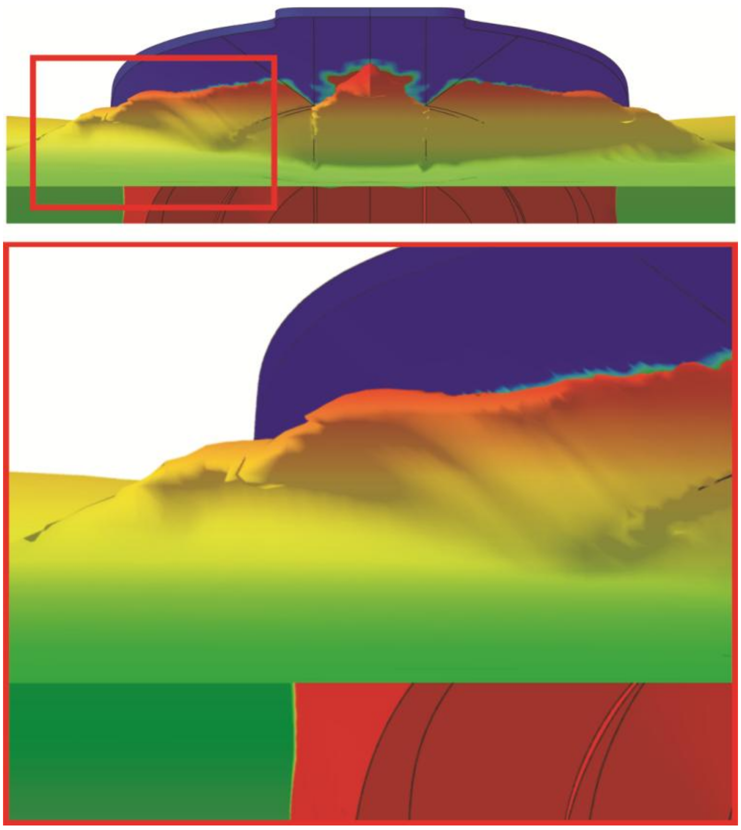

Fig. 4.
Overturning Fn=0.657 (6m/s)

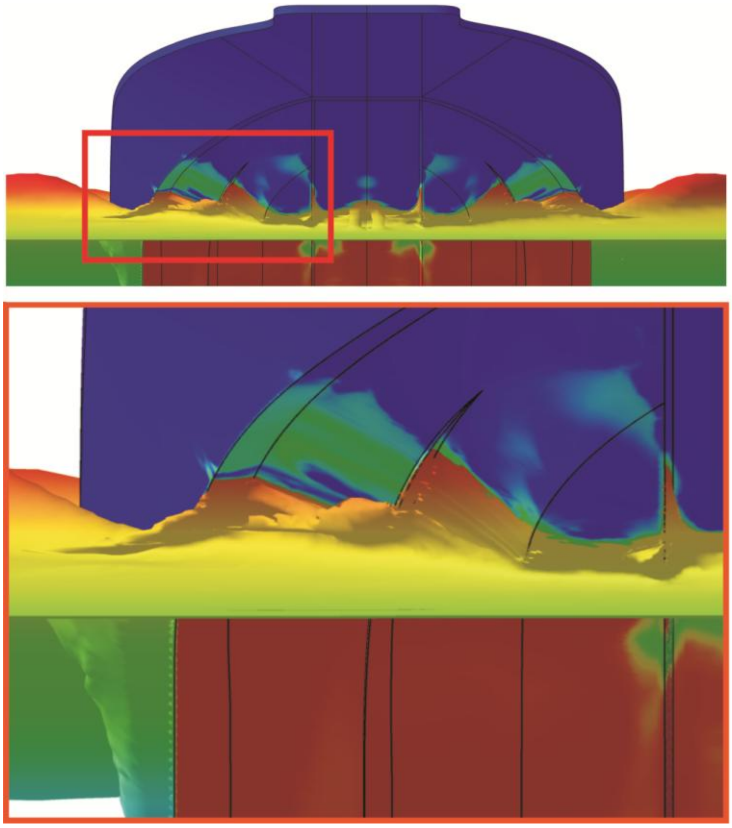

Fig. 5.
Spray sheet Fn=0.986 (9m/s)

The effect of the semitunnel shape design that intended to reduce the total resistance by reducing the frictional resistance with the help of air entrapment was partially achieved, as the mass fraction pictures revealed. Further studies will be conducted with various hull shapes to investigate the air entrapment and total resistance correlation. In Figure 6 there are presented the front, bottom and side view of the wetted hull surface for all the 7 speed cases considered in this study. It can be observed that the planning condition begins in the vicinity of Fn=1. The reversed chines and spray rails play a significant role in directing the flow alongside the hull and creating the intended flow separation.

3. Conclusion

The method described in this paper captured the planning phenomenon using the numerical analysis. The comparison with the Savitsky (1969) method revealed comparable results for Fn>1; within the smaller velocities range, the results are substantially different, due to the fact that planning phenomenon is considered to begin at Fn > 1-1.2, therefore the velocities corresponding to Fn less than 1 seems to be not accurately predicted by Savitsky (1969) method, thus leading to divergent results compared with the CFD solution, as shown in the Figures 9 and 10. The CFD numerical approach can offer information that help the improvement of the hull shapes, especially in the bow area for flow optimization in the preplanning phase. For the velocities 0.66 <Fn <0.99 it is shown that the flow of water has the tendency to climb on the semi tunnel extension above the waterline (figure 6), leading to an additional resistance and probably delaying the transition to planning regime. Further studies with a modified bow shape will be conducted in order to improve the spray shape and hull resistance.

A STOPPING MANEUVER BASED APPROACH FOR CONFLICT SITUATION ASSESSMENTS ON THE RIVER DANUBE

Aleksandar Radonjić[1], Vladislav Maraš[2]
[1,2] University of Belgrade, Faculty of Transport and Traffic Engineering, Belgrade, Serbia

Abstract: Due to introduction of River Information Services on the rivers of Serbia at the start of the 2014 it is possible to investigate collision-involved ships on the Danube river which is the most congested fairway in Serbia. The main interest in the fairway should be critical sectors where the waterways are busy and where the potential for the collisions is high. The study in this paper aims to evaluate the risk of potential collisions among ships in the river Danube and relies on the former studies in this scientific area. It also brings some new aspects characteristic for the river fairways and proposes new method for the calculation of the relationships among ship positions, ship speeds and ship conflicts.

Keywords: safe distance, conflict distance, collision distance, inland waterways.

1. Introduction

The inland waterway transport in Serbia plays a significant role in the transport of cargo to and from Serbian river ports, annually transporting from 2 to 6 million tons of goods (Strategy of the development of inland waterway transport, 2014). This transport is carried out by roughly 2.500 ships mostly consisted of push barges and self propelled barges owned by Serbian and foreign inland waterway transport companies and mainly companies with a small number of ships (Strategy of the development of inland waterway transport, 2014). Inland waterway transport decreased (in terms of tone-km) by over 50% from 1990 to 2011 in Republic of Serbia, but also increased by over 25% between 2012 and 2015. Given the increased transport over the road network in the last 25 years (from 1990 to 2015), it is expecting to open more opportunities for freight transport by barges and overall by inland waterway ships. Over the last three years (from 2012 to 2015) it is recorded more inland transportation units and self propelled barges of inland ships in Republic of Serbia (Statistical Office of the Republic of Serbia). It is also expecting increase in number of inland transportation units by 10.5% from 2012 to 2020 and by 34.4% from 2012 to 2025 (Strategy of the development of inland waterway transport, 2014).

Because of the increase of the transportation and the expectation of the increase of the transportation, traffic on the river fairways in Serbia is expected to grow from 2012 to 2025. It will bring the growth of the ship movements in the Serbian rivers and especially on the river Danube. Increased number of ship movements could open the possibility of the increased number of accidents among the ships (Yip, 2008 and Qu et al., 2011).

Serbian authorities responsible for the inland waterway transportation have already adopted River Information Services (RIS) that relies on Automatic Identification System (AIS) and Electronic Chart and Information Systems (ECDIS). Port authorities also rely on RIS. They have already experimented with the various safety systems that could help them avoid risks of different critical situations like collisions or grounding of the ships (Radonjic et al., 2007) and enable them safer navigation for the ships. The effectiveness of these experiments is under the question.

Lot of authors and researchers established various models and techniques for the navigational risk assessment over the past years. Great number of these models is based on the evaluation of the occurrence frequency of navigational accidents. However, navigational accidents cannot be evaluated only by occurrence frequency. They also depend on maneuverability of the ships involved in accidents for example. Therefore, the authors are concerned about the navigational accidents related to ship maneuverability in this paper.

The main attention in this paper is on the critical distance and the distance and area between critical distance and collision distance between two ships involved in navigational accident. Critical distance is defined as a measurement of distance between two vessels involved in navigational accident that are on collision course (Montewka et al., 2010).

It is of a crucial importance to regularly determine critical distance between two ships involved in navigational accident. The distance has to be correctly counted relying on the different factors that are already implemented in the navigation of ships. These factors include the type of fairways, special areas of the fairways where the congestion can be higher than in the other parts of fairway, the type of ships involved in navigational accidents, hydro-meteorological parameters, ship maneuverability, human behavior etc. The emphasis is put on the parameters which significantly contribute in turning critical distance to collision of ships in this paper. Parameters are then included in the process of determination of safe critical distance and safe critical time between two ships that are on the collision course.

The first isolated factor refers to a river or a sea fairways. In this paper only river fairways will be considered because the navigation of ships in the Republic Serbia takes place on the rivers. The example will be on the river Danube.

The second factor that contributes to safe critical distance is the ship maneuverability. Ship motions on the rivers are mostly forward except in the curvatures. Ships are sailing on the designed and marked fairways. In the waters out of the marked fairways there is no confirmation of the authorities that the navigation is safe. It indicates that every ship out of the labeled fairway could find itself in the danger of striding or could encounter stationary vessels and collide with them. Navigation rules also suggest that some ships in downstream navigation have a priority of the passages

[1] Corresponding author: a.radonjic@sf.bg.ac.rs

independently of the movement of the second ship included in the conflict situation for example. This is the reason why the influence of the stopping maneuver on the critical distance will be investigated in this paper.
The aim of this paper is to determine safe distance, conflict distance and collision distance on the basis of the calculations presented in (Mou et al., 2010) with added stopping distance maneuver. The aim is also to show that critical distance is very dependable on stopping maneuver. In the approach presented in this paper, it is assumed that a collision between two ships becomes reality when the distance between the ships is not enough to perform efficient stopping distance maneuver. The space and time required for a second ship to perform a stopping distance maneuver depends mostly on ship hydrodynamics and maneuverability features.
Safe distance is distance between ships' centers of gravity where the probability for the collision of two ships is equal to 0. Conflict distance is distance between ships' centers of gravity where the probability for the collision of two ships is between 0 and 1. Collision distance is distance between ships' centers of gravity where the probability for the collision of two ships is equal to 1. Safe distance, conflict distance and collision distance are presented graphically in Fig. 1.

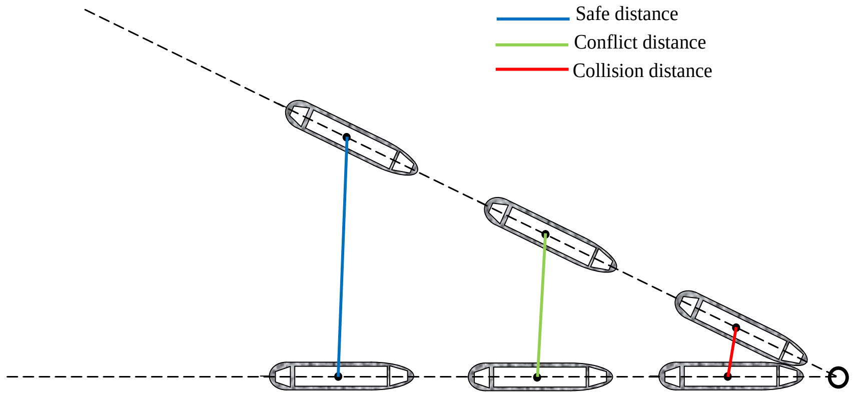

Fig. 1.
Safe distance, conflict distance and collision distance

Special attention is focused on conflict distance. Conflict distance is calculated by implementing ship stopping distance into the calculus.
Only one conflict situation is investigated. It is situation when the first ship has the right to pass without stopping according to navigational rules and therefore second ship is obliged to perform stopping maneuver. It is assumed that ships are navigating in deep water with the flow. Flow velocity is implemented in the final result. The minimum distance between two ships on collision course is conducted for self propelled barges, but is intended for all types of river ships in future work. Conflict situations are repeated for angles of course intersections from 11° to 60° which are the most frequent on the river Danube among all other traffic situations.
The entire estimation of the critical distance and collision distance is done with data transmitted from RIS and from ships.

2. Literature review

Many papers investigating ship collisions and critical distances have been presented in the recent years. Fujii's (Fujii et al., 1974) method rated as the most popular due to its simplicity. However, it didn't take into account ship dynamics and it assumes that a collision is on the track when two ships come to a distance defined as the collision diameter. Another approach based on the critical distance between two ships was applied to perform a risk analysis for a large suspension bridge by Pedersen (2002), in which the critical distance between two ships was assumed a constant value, and only head-on encounters were considered.
The other paper comes from Macduff (1974) and states that the number of ship conflicts multiplied by a causation probability. There are various mathematical models that propose to estimate the ship collision frequency such as from Tan and Otay (1999), Fowler (2000), Szlapczynski (2006) and Wang (2010).
Another group of papers related with navigational accidents make up computer simulation-based approaches and they quantitatively examine various navigational safety issues (Dand, 2001 and Zhang, 2006). The most recent paper in this scientific area is from Tian et al. (2017). The authors proposed quantitative risk assessment model which take into account the occurrence frequency and consequence of ship collisions. They made a collision frequency estimation model to evaluate the occurrence frequency of ships being involved in collisions.
Collision frequency estimation is more represented in the literature than mechanical models and simulation methods for collision consequence estimation. Servis and Samuelides (1999) paper refers to the finite element simulation of ship collisions. They proposed finite element technique for the assessment of the collision behavior of a ship under the defined collision scenario, for the relative comparison of structural arrangements and for the validation of analytical techniques for collision analysis.

The idea ship's maneuverability implementation into a collision assessment model was presented by Curtis (1986) for the first time. His model was restricted to one ship type with the overtaking and head-on maneuvers.
In 2010 (Montewka et al., 2010) presented a new approach for collision modeling probability which includes ship maneuverability. They used ship motion model to determine the minimum distance to collision for the waterways between Helsinki and Tallinn and for the summer traffic.
In the opinion of the authors there are very few papers that are dealing with the ship maneuverability as a factor that increase or decrease influence on navigational accidents. The contribution of this paper is in improvement of the existing models described in Mou et al. (2010) and Montewka. et al (2010) presented in Tian et al. (2017). Also, the model is formulated for the navigation on the rivers and can be used for river ships.

3. Model formulation

3.1. Definition of ship conflict (Assessment of minimum distance to collision)

According to Montewka et al. (2010) there are three conflict situations on the fairways based on the course difference of two ships:

1. Overtaking conflict where ships lye on almost the same courses and the course difference is not more than 10°,
2. Head-on conflicts in which two ships' courses differ in the range between 170° and 190°,
3. Crossing conflict in which the difference between ships' courses falls in the all other ranges not mentioned before from 0° to 360°.

Conflict distance on the river is the same as in the Montewka et al. (2010) with one crucial difference. It is determined on the base of ship motion in which one ship has the forward motion while other ship tries to cross over the first ships' forward course with the specified angle of course. In this paper ships' courses that differ in the range between 10° and 60° will be investigated. Other combinations of ships' course differences for crossing conflicts are not interesting because the major number of ship encounters on the river Danube falls in the specified ranges between 10° and 60°.
The following assumptions were made:

- Ships are navigating at full approach speed,
- The ships start their maneuvers according to variants described in introduction,
- The settings of the steering gear and propulsion during the maneuver are constant,
- The initial course of the first ship is always 0°,
- The initial course of the second ship is between 10° and 60°,
- Both ships stays on the initial courses,
- Only stopping distance maneuver is performed.

3.2. Definition of collision distance, conflict distance and safe distance

The collision between two ships becomes real when the distance between two ships is to low to perform efficient maneuvers to avoid collision (Montewka et al., 2010). Collision distance in this paper is the distance between two centers of gravity defined in a moment when two ships contact with their leftmost and rightmost points in the front of their hulls (see Fig. 1). Fig. 2 describes geometrically the collision distance.

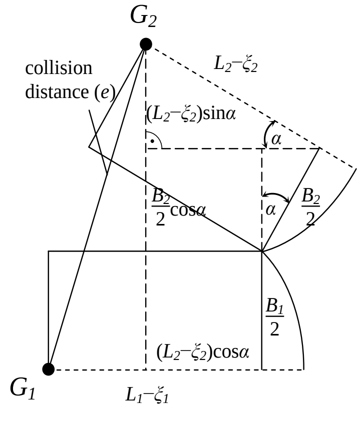

Fig. 2.
Geometrical presentation of collision distance

The main factors relevant to determine collision distance (e) are ships' length between perpendiculars (L), ships' beam (B), angle of intersection (α) and horizontal component of the center of gravity (ξ). From Fig. 2. collision distance (e) is:

$$e = \sqrt{\left[L_1 - \xi_1 - (L_2 - \xi_2)\cos\alpha + \frac{B_2}{2}\sin\alpha\right]^2 + \left[(L_2 - \xi_2)\sin\alpha + \frac{B_2}{2}\cos\alpha + \frac{B_1}{2}\right]^2} \quad (1)$$

Conflict distance is the distance between two centers of gravity defined in a moment when captain of the second ship can react in order to avoid collision with the first ship (see Fig. 1). Reaction is equal to necessary commands that are related to stopping maneuver in this paper. Fig. 3 describes geometrically the conflict distance.

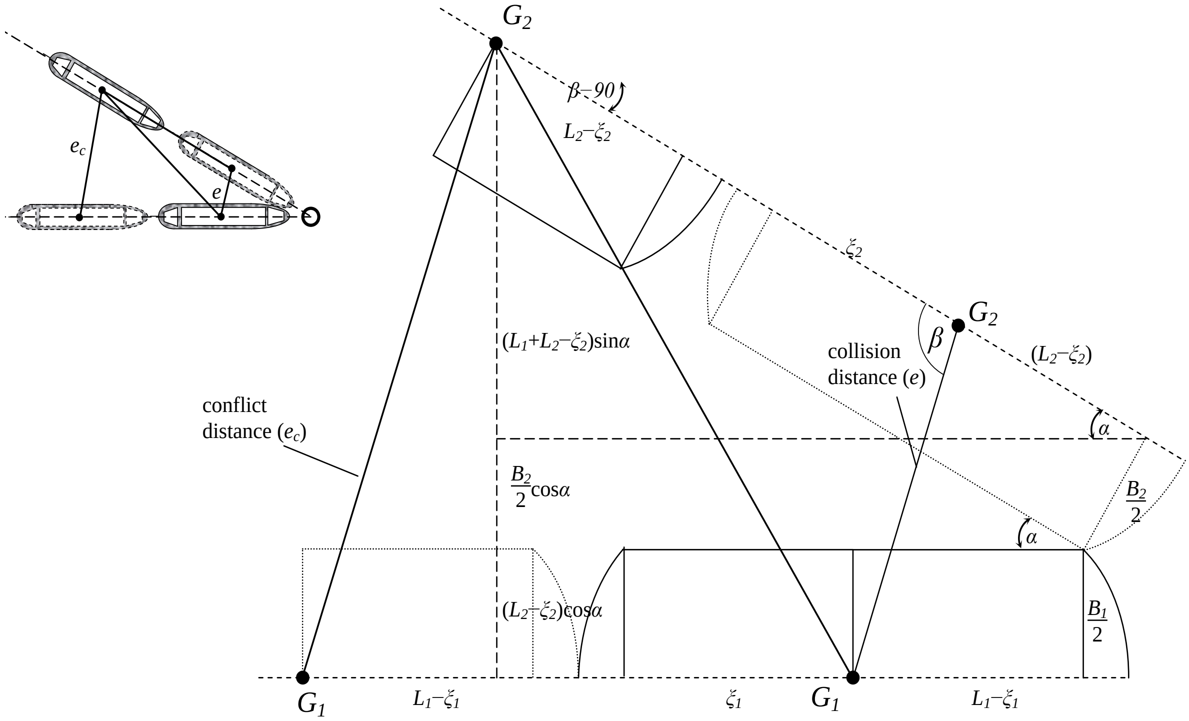

Fig. 3.
Geometrical presentation of conflict distance

If the two ships move with the same speeds and are not to collide the minimum horizontal difference between collision distance and conflict distance is equal to the length of the first ship (L_1). If the second ship is somewhere between collision distance and conflict distance on his path and course, the collision can be avoided if the captain of the second ship react in time enough to stop the ship with the stopping maneuver. Conflict distance and collision distance are presented in Fig. 3 with the parallel lines which is the condition that results from assumption that ships are navigating at full approach speed. From Fig. 3. conflict distance (e_c) is:

$$e_c = \sqrt{\left[2L_1 - \xi_1 - (L_2 - \xi_2)\cos\alpha + \frac{B_2}{2}\sin\alpha\right]^2 + \left[(L_1 + L_2 - \xi_2)\sin\alpha + \frac{B_2}{2}\cos\alpha + \frac{B_1}{2}\right]^2} \quad (2)$$

Safe distance is distance between two centers of gravity longer than conflict distance.

3.3. Stopping maneuver

A ships' stopping distance is estimated with the following formulae (IMO, 2003 and D'Arcangelo, 1957):

$$(m + m_x)\cdot\frac{du}{dt} = -T - R \quad (3)$$

Where; m: the ship mass, m_x: surge added mass, R: ship resistance, T: propeller thrust and u: ship speed.
Two basic assumptions are applied:

1) The ship's resistance is calculated according to (Basin et al., 1976 in Latorre et al., 1982, Kreculj and Colic 2008 and Zvonkov, 1956),

2) The propeller thrust is a linear function of distance the ship travels until an astern value of T_S is reached, after which the thrust remains constant (D'Arcangelo, 1957). This is illustrated in Fig. 4.

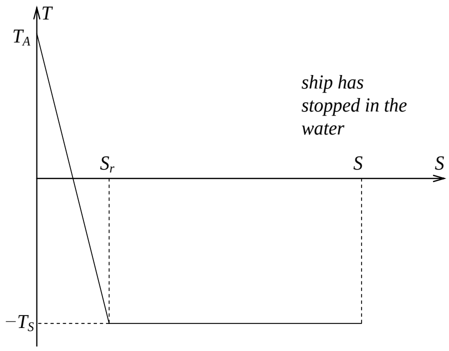

Fig. 4.
Assumed thrust acting on ship during stopping maneuver Source: (Varyani, 2009)

With these assumptions, the equation (1) is solved analytically and the stopping distance and stopping time are as follows (Varyani and Krishnankutty, 2009 and D'Arcangelo, 1957):

$$S = \frac{1}{2}u_o t_r + \frac{(m + m_x)\cdot u_o}{2R_o}\cdot \log_e\left(1 + \frac{R_o}{T_S}\right) \tag{4}$$

$$t = \frac{1}{2}t_r + \frac{(m + m_x)\cdot u_o}{g\cdot R_o}\cdot\left(\frac{R_o}{T_S}\right)^{1/2} \tag{5}$$

where t_r is the time at which the reverse thrust (T_S) is achieved, u_o, R_o, T_S are the approach speed, the resistance at approach speed and astern thrust respectively.

4. Numerical example (computational results)

Two self-propelled barges are used for numerical example. Their principal dimensions are:

L_1 = 74.80 m L_2 = 85.98 m
B_1 = 12.01 m B_2 = 8.44 m
d_1 = 0.58 d_2 = 0.68 m
m_1 = 355,800 kg m_2 = 384,900 kg

Computational results are shown in Table 1.

Table 1
Stopping time and stopping distance for the second ship

According to Table 1 time required to achieve astern thrust is 20 seconds. This time is average value from Olshamovskeih et al. (1979). The length of the first ship is 74.8 m which means that second ship has to late about 15.39 seconds to 31.68 seconds depending on the ship speed between 8.5 km/h to 17.5 km/h. It is calculated that even if the second ship react immediately she can enter the collision distance depending on the speed of the ships in the moment before stopping maneuver. Entering the collision distance starts to appear when the ship speed is 11.5 km/h. As the angle between two ships increases the critical ship speed increases and at about 29º to 60º conflict distance according to formula **Error! Reference source not found.Error! Reference source not found.** can be considered as the right moment to start stopping distance maneuver. At angles bellow 29º if the second ship react immediately after entering the conflict distance she will not be able to avoid collision with the first ship with the higher speeds.

5. Conclusion

In this paper stopping distance based approach for conflict situation assessments on the river Danube is proposed. Authors tried to improve previous works related to conflict distances and collision distances and to set previous models and methods to the river Danube traffic. Critical distances in this paper between two ships on collision courses are conducted for self propelled barges. Other ship types plan to be implemented in future work.
Firstly, safe distance, conflict distance and collision distance are defined. Then, stopping maneuver is proposed to implement in the calculation of distance to avoid collision. After already obtained results by numerical example it is concluded that second ship can avoid collision if start to stop at the point where conflict distance began. However, for the angles of course intersections bellow 29º conflict distance has to be recalculated as the second ship cannot avoid collision even if react at the time proposed in the paper. Question remains what is the safe time for the second ship to start with stopping distance maneuver for the angles bellow 29º.
It was proved that proposed calculus can be applied on self-propelled barges and on other river ships. There is also advantage of the proposed calculus when there is not enough information about the accidents on the river Danube as it is based on stopping distance maneuver.
As a next step, the authors are studying the impact of changes in the numerical example when self-propelled barges are replaced with barge convoys. Also, there is some conflict situation where river ships can perform turning maneuver to avoid collision and this maneuver can be added to numerical example.

THEORETICAL APPROACH FOR FINANCING QUESTION OF FERRYBOATS: A CASE STUDY IN HUNGARY

Adam Torok[1]

[1] BME – Budapest University of Technology and Economics, Department of Transport Technology and Economics, Budapest, Hungary

Abstract: Nowadays infrastructure development and maintenance needs governmental financial support. In this paper the financing question of ferryboats are investigated in Hungary. In Hungary ferryboats are fundamental part of transport infrastructure, where river crossing is essential but no bridge were being built. In this paper author has investigated the phenomena and designed a theoretical method in order to scientifically ground the financial support of ferryboats in Hungary. There is a very strong constrain from political side. That is the maximum available financial resource. Therefore the model needs to distribute the available financial support taking into consideration social, economic and technical parameters. Author have designed a multi-criteria decision support tool in MS-Excel in order to be able to find the optimal solution of distribution of financial resources.

Keywords: ferryboat, finance, multi-criteria, assignment.

1. Introduction – Importance of ferry boats

Nowadays infrastructure development and maintenance needs governmental financial support it cannot be financed from market directly (Škrinjar, et al., 2015). In this paper the financing question of ferryboats are investigated in Hungary in 2014 and 2015. In Hungary ferryboats are fundamental part of transport infrastructure – Hungary has more than 60 ferryboat services (like Fig. 1.) on rivers and lakes -, where river or lake crossing is essential but no bridge were being built. Ferryboats also providing element support on intercity public transport (Černý et al., 2014) that is financed by government in Hungary.

Fig. 1.
Ferryboat on Tisza
Source: http://network.hu/babairen/kepek/irenke_fotoi/tiszai_komp

In this paper author has investigated the phenomena and designed a theoretical method in order to scientifically ground the financial support of ferryboats in Hungary. As public transport needs to be financed by the government and public financial resources are limited (Gaal et. al., 2015) a distribution and assigning strategy were needed. In previous years the financing support were distributed in equally or in case of distortion the cause were not scientifically clarified. Therefore in this paper author propose a multi-criteria model for scientific distribution of limited financial support between ferryboats based on their performance, role in infrastructure, or avoidance of emission due to the shorter way of transport (Toşa et. al., 2015; Ivković et. al., 2016). The hypothesis were that **ferryboats are playing important role in transport** of Hungary **based on their** network location and **performance and their maintenance and development needs to be financed** but not equally **therefore a scientifically grounded method needs to be built**.

[1] Corresponding author: atorok@kgazd.bme.hu

2. Methodology

Nowadays in Hungary 61 ferryboats are operational, from these 26 on Danube, 20 on Tisza, 6 on Bodrog, 3 on Szamoson, 2 on Kőrös, 2 on Sajó, 1 on lake Balaton and finally 1 on lake Velence are located. Ministry of National Develoment is responsible for Transport and has provided data as location of ferryboats, type of ferryboats, maximum carrying capacity of ferryboats (Fig. 2a., Fig. 2b., Fig. 2c.), role in network (temporary or permanent) and role in the region (connects national or regional or local roads and areas). The operation of these ferryboats saves time, energy and harmful emission on national level (Masoumi and Soltanzadeh, 2014).

Fig. 2a.
Ferryboat with maximum carrying capacity 150 t

Fig. 2c.
Ferryboat with maximum carrying capacity 10-20 t
Source: http://www.geocaching.hu/caches.geo?id=4012

Ministry also provided traffic data as ratio of work and non-work related traffic and hourly traffic volume as lorries, as passenger cars and as persons. In order to get more precise info on role of ferry boats in the network the length of detour were calculated as if the ferryboat were not existed in order to later estimate the social benefits of ferryboats (travel time shortage and emission reduction). Based on the provided and collected data a consistent database were conducted (Cserháti and Csizsár, 2016) coherent with accepted practice as a suitable solid basis of multi-criteria decision support tool. For this the criteria were weighted based on the consultation with experts of Ministry as follows (Fig. 3.):

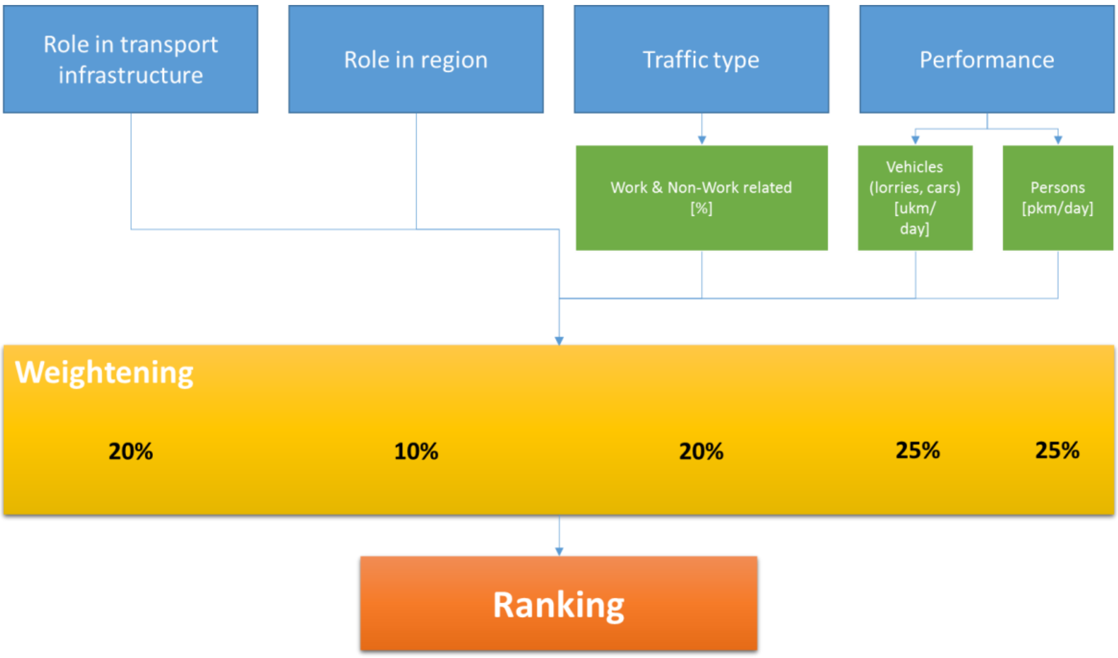

Fig. 3.
Concept of decision support tool
Source: own compilation

The monetary value of emission and fuel consumption reduction were calculated based on (1):

$$C_{fuel} = \left(\sum_{i=1}^{m} e_i \cdot d \right) \cdot v_j \quad (1)$$

Where; C_{fuel}: Private cost of fuel consumption surplus [HUF], e_i: fuel consumption of vehicle i [litre/100 km] based on the statistical value of Hungarian vehicle fleet consumption analysis, d: estimated distance of detour [km], v_j: cost factor of fuel j [HUF/litre] (Meszaros and Torok, 2014)

The monetary value of travel time saving were calculated based on (2):

$$TTS = \left(\sum_{j=1}^{n} N_j \cdot \Delta TT\right) \cdot \tau \tag{2}$$

Where; TTS: Monetary value if travel time saving [HUF], Nj: Number of passengers and vehicles, ΔTT: Change in travel time [hour] – please note that it is surely positive in case of closure of ferryboats, τ: Monetary value of travel time [HUF/h] (Meszaros and Torok, 2014).

3. Results

Based on the traffic circumstances and calculated length of detour author could determine the external revenue of ferryboats based on the travel time shortage on not to use the detour and decrease of emission. Based on their performance and their role on network with the help multi-criteria decision support tool the ranked list of ferryboats and their governmental financial support could be generated. Not only the ranking could be done but also could be investigated the result of closure of any ferryboats as concluded in *Table 1*:

Table 1
External revenue of ferryboats

Component	Value [EUR]
Monetary value of Travel Time Shortage	41 500
Monetary value of emission reduction	535 500

Source: own compilation

4. Conclusion

In this paper a multi-criteria tool is being introduced that not only capable of ranking by the limit financial support of national funds on ferryboats but also capable of estimating the external revenues and loses of ferryboats whenever their operation is maintained or whenever they are closed. With this decision support tool the political decision maker can rank the ferryboats and can decide their limited financial support. Great disadvantage of the tool that needs that data updated on yearly bases. Even closure of one ferryboats could have effect on the whole system as could influence the detour length and therefore the external revenues. Later author plan to develop the model and extend with assignment module in order to be able assess development project separately. Ferryboats are playing important role in transport of Hungary as it can be seen. Based on their network location and performance their maintenance and development push different obligation to government or local authority. Therefore their differentiated finance need to be solved on a solid scientific ground.

SESSION 5: MARITIME TRANSPORT AND PORTS RESEARCH

MARITIME PASSENGER TRANSPORT IN THE ADRIATIC-IONIAN REGION

Maja Stojaković[1], Boštjan Žlak[2], Marina Zanne[3], Elen Twrdy[4]

[1,2,3,4] *Faculty of Maritime studies and transport, Portorož, Slovenia*

Abstract: Maritime passenger transport represents one of the most important modes of passenger transport in Europe. In 2013, the total number of passengers passing through EU-28 ports reached 400 million, which was a 0.5% increase over the previous year. The Adriatic-Ionian region, for one, is gaining importance within Europe with almost five million cruise passengers and seventeen million ferry passengers in 2013. Based on the data gathered through the EA SEA-WAY project, we have prepared an overview of the current state of cruise and ferry passenger traffic in the Adriatic-Ionian region, identified ports holding the largest traffic shares and presented guidelines for the future development of maritime passenger traffic within the region.

Keywords: maritime passenger transport, cruise traffic, ferry traffic, Adriatic-Ionian region.

1. Introduction

Recently, maritime passenger transport has become one of the most important modes of passenger transport in Europe. We can attribute this to its positive ecological and economic impact and to important stimulating actions taken by the European Union. Maritime passenger transport is composed of cruise transport and non-cruise transport, represented by ferry transport (EUROSTAT, 2015).
In 2013, the total number of passengers passing through EU-28 ports reached 400 million, which was a 0.5% increase over the previous year. Ferry lines transported the majority of passengers, while only 3.4% belonged to cruise shipping. Europe represents an extremely ferry intensive market, which is divided into two main ones - Northern Europe, including the Baltic, and all of the Mediterranean (EUROSTAT, 2015). In 2013, ferry ships in the Mediterranean region transported roughly 460 million passengers and 37 million cars. There is a dense network of ferry routes around the coasts of Italy, the Balkan states, the Greek Islands and between the Balearics and the mainland, with many of the ports offering services for 5 to 10 million (or even more) passengers per year.
According to Wergeland (Wergeland, 2012), the domestic market in Greece, with all the traffic among the myriad islands, represents one of the world's largest ferry markets and one of the main for the Adriatic.
Although cruise shipping represented only 3.4% of the passengers in EU-28 ports in 2013, this segment became a very important component of the maritime and tourism sector of the small number of ports and countries where it is concentrated. In 2013 there were 21.3 million cruise passengers, 51% coming from the USA (51%), while 30% originated from European countries (Cruise Lines International Association). More than 80% of the total number of cruise passengers embarking and disembarking in European ports did so in Italy, Spain, the United Kingdom and Germany. In the cruise sector, the Mediterranean represents one of the key regions in the world with a 21.7% share of passengers, second only to the Caribbean (34.4%). The Mediterranean cruise market can be divided into four major sub-regions, the western Mediterranean, the Adriatic, the eastern Mediterranean and the Black Sea. In 2013, the Adriatic sub-region ranked second, immediately after the western Mediterranean with a 22.3% market share.
The Adratic-Ionian region consists of about 20 ports that are engaged in cruise shipping and around 40 ports that perform ferry transport and has great growth potential. As can be seen from Figure 1 the maritime passenger transport is quite dense in this zone.

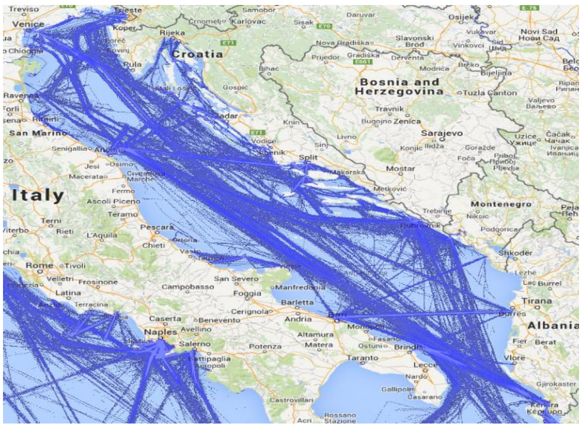

Fig. 1.
Passenger shipping in Adriatic-Ionian region
Source: (Marine traffic, 2014)

[1] Corresponding author: maja.stojakovic@fpp.uni-lj.si

There were over than 5.2 million cruise passenger movements in 2013, which is an increase of 4.6% compared to 2012 and approximately 17 million ferry passengers, a drop of 0.9% attributable mainly to the construction of new bridges and the consequent closure of some ferry links. Nevertheless, predictions suggest growth in both sectors in the coming years (Turismo, 2014).
This paper presents an overview of the most important cruise and ferry ports in the Adriatic–Ionian region, determines their competitive position in the region through port portfolio analysis and presents the potential for their development in the future.

2. Adriatic – Ionian cruise sector

The Adriatic sub-region is the second most important in the Mediterranean, immediately after the western Mediterranean. The number of passengers carried by cruisers in the Adriatic Sea steadily increased from 2009 to 2013. In 2009, the number of passenger visits reached 3.7 million, while in 2013 it reached 5.2 million, an increase of almost 40%. The number of cruise calls in the Adriatic ports also increased over this period. In 2009, there were 2,919 cruise ship calls, while in 2013 this number was 3,219, a growth of 10.28% (MedCruise, 2014a).
In 2013, the number of passengers in Adriatic ports increased by 6.2% over 2012, although the number of calls in the region decreased by 0.5% in the same year. These numbers represent a share of 19% of the total passenger visits to the Mediterranean region in 2013 and 22.3% of the cruise calls that took place in the Mediterranean ports (MedCruise, 2014b).
Despite the fact that in 2013 Adriatic ports received fewer ships than in 2012 this fact did not adversely affect the total number of passengers carried, implying that carriers using bigger ships, especially in larger ports. According to the traffic forecasts, there is a strong possibility that such trends will continue into the future. Ports will therefore have to optimize their existing port facilities, where necessary, so they will be able to receive larger ships.
The two countries that have leading roles in the Adriatic cruise market are Italy and Croatia, accounting in 2013 for approximately 80% of total cruise passengers.

Source: Adriatic Sea Tourism Report 2014

Italy registered the highest number (2,702,789) of tourists on cruises in the Adriatic Sea in 2013, a 51.79% market share. Croatia was next with a 26.47% share and 1,381,572 tourists, and Greece, included though it is not in the Adriatic, was third, with a 14.36% share. Slovenia had quite a small (1.29%) share, which is to be expected for it has just one port (Turismo, 2014).
Both leading countries recorded smaller numbers of incoming cruisers in 2013 (Italy -15.1%; Croatia -2.4%). According to the Adriatic Sea Tourism Report, the reason for such a drop in Italy was mainly the reduced number of cruise calls to the main Italian ports. A similar situation occurred in certain Croatian ports, while the country with the highest growth in ship calls was Slovenia.

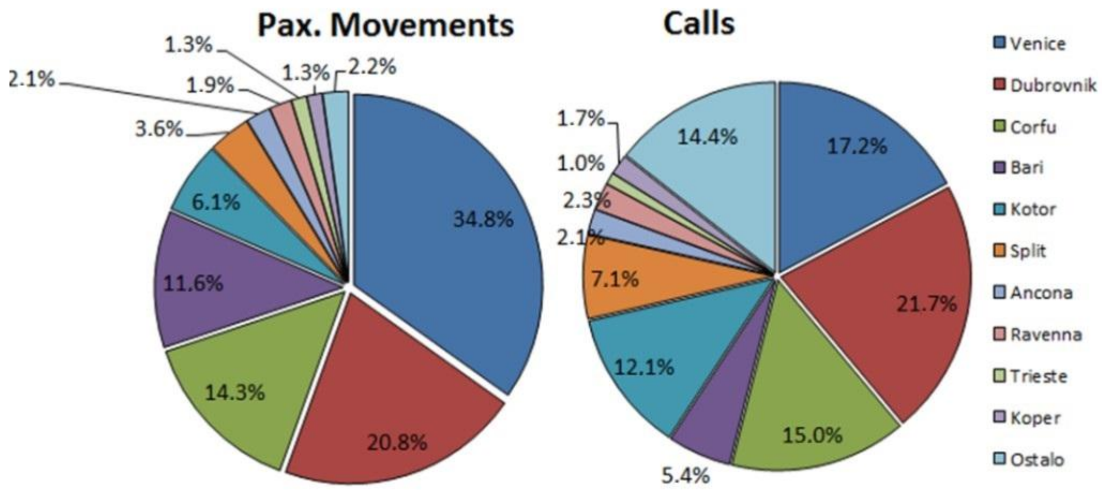

Fig. 2.
Traffic Share of the First 10 Cruise Destinations Among Adriatic Ports (2013)
Source: Adopted from the Adriatic Sea Tourism Report 2014

Figure 1 presents traffic shares regarding passenger movements and cruise calls of ten major cruise ports in the Adriatic. Venice and Dubrovnik, ranked first and second, together recorded half of all passenger movements in the Adriatic region (Venice 34.8%, Dubrovnik 20.8%).
According to the Adriatic Sea Tourism Report, in the next year the number of cruise passengers and cruise ship calls to the major Adriatic ports is expected to decrease. Traffic in Venice is expected to decrease by 7%, which is mainly attributable to restrictions regarding the acceptance of larger ships that were adopted in 2013. Meanwhile, Dubrovnik and Corfu are forecasted to have a 17% and 15% decrease, respectively. The main reason is in passenger distribution changes; that is, the increase of passenger movements towards ports that until now have previously been less visited. Smaller ports will therefore have more opportunities to attract passengers from larger ports. As Venice is considered the biggest attraction in the Adriatic, small ports will have major opportunities to attract passengers and large cruise ships if they have good terminal facilities in the proximity of Venice, as from those locations inland trips to the city of Venice can easily be organized.
For further analysis of the Adriatic region, nine Adriatic cruise ports that were included in the EA SEA-WAY project were selected, together with the port of Venice, as it is the main Adriatic cruise port.

2.1. Analysis of the selected cruise ports in the Adriatic-Ionian region

The study conducted within the EA SEA-WAY project included the Albanian port of Sarande, the Greek port of Igoumenitsa, the Italian ports, Ancona, Bari, Chioggia, Ravenna, and Trieste, along with the Slovenian port of Koper.
According to J.Corres (Corres and Papapchristou, 2013) and B. Lekakou (Lekakou et all., 2009) cruise ports can be divided into three classes with attendant subclasses. This includes hub ports (classes I, II and III), hybrid ports (classes A, B and C) and destination ports (classes 1, 2 and 3). A hub port serves as a homeport, meaning that it has the entire infrastructure required for embarkation or disembarkation of passengers and a place where passengers may begin or end their journeys. On the other hand, a destination port serves only as a port of call, a port where a ship only visits for a short period of time (often just for a few hours), but doesn´t provide services related to embarking/disembarking. Passengers at these ports don´t begin or end their journeys. The hybrid port is considered a hub port and a destination port at the same time. These ports usually have perfect conditions for embarking and disembarking including great hinterland connections by road, rail and particularly air.
Figure 3 clearly shows the two ports that receive the most passengers (Venice and Dubrovnik), which also top of the list in number of calls (Venice 548 and Dubrovnik 843, respectively). Although Dubrovnik has more calls, the ships tend to be smaller, carrying fewer passengers. Most likely, due to exceptional air and rail connections, Venice is classified as Hybrid A, while we can consider Dubrovnik as a destination port class 1, as the homeport operations are still too few for it to be considered a hybrid port. The two ports are both world-renowned destinations, UNESCO World heritage sites and thus major tourist attractions.

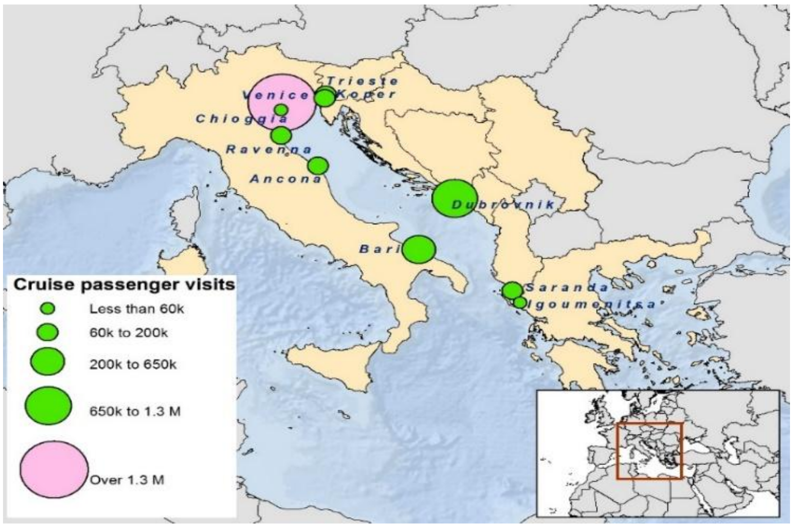

Fig. 3.
Cruise Passenger Visits, Adriatic-Ionian Region, 2013
Source: Adopted from the MedCruise, 2014

According to Lekakou (Lekakou et al., 2009)**,** the most important factors that affect the choice of ports to be included in a cruise line's itinerary are: port services to cruise ships, natural port characteristics, port services to passengers, port infrastructure, attractive touristic areas and activities, port service cost, port efficiency, port management, provision of intermodal transport, political conditions and regulatory framework, city amenities, and proximity to markets for cruise passengers. An important role in port choice is attributed to the port hinterland connections within the region. The vicinity of an airport proved to be one of the most important factors.

Fig. 4.
Airports In the Vicinity of Venice, Trieste and Dubrovnik
Source: Adapted from google maps

Venice fulfils all of these conditions and is considered the most important cruise port of the Adriatic-Ionian region. As shown in Figure 4, Venice also has the best air connections among the analysed ports. Not only does it have two international airports in the near vicinity, two more airports are available within less than an hour's drive. A valid alternative to the port of Venice is the port of Trieste, which is already gaining importance. The local cultural attractions and the proximity to its local airport, and especially to Venice, are reasons for its continuous development as a hybrid port. The port of Dubrovnik is the second most visited destination of the Adriatic-Ionian region and its status could even improve in the future as it represents a great tourist attraction. It is connected to one international airport.

2.2. Portfolio analysis of the selected Adriatic-Ionian cruise ports

To determine the competitive position of the analysed cruise ports, we used a rather simplistic approach with the "port portfolio analysis". It is usually used as a tool in strategic positioning analysis and offers a graphical representation of results within a "growth-share" matrix (Bagis and Dooms, 2014) for a certain timeframe.
The results in the matrix are based on annual growth rate data gathered from port websites and calculated average market share. Each of the matrix quadrants represent a port's role in the cruise market for the observed time span, based on their average market share and average annual growth, and the quadrants were determined by the average of all the ports' annual growth (12.1%) and average market share (10%). The ports have recorded rather large fluctuations of passengers in recent years; therefore, it is unlikely that the time span we used for observations is sufficient. Some of the analysed ports are in the early stages of their cruise destination development, lines established just a few years ago (e.g., Igoumenitsa, with almost no market share is thus not visible in the matrix). The cruise terminal in the port of Ravenna

was built in 2010 and within two years received cruise passenger traffic of more than 150,000 passengers, declining over the next two years to what seems will be a stable 100,000 passengers yearly.
Data in the matrix (Fig. 5) shows that the majority of the ports have a rather small market share (figures by the ports represent market share among selected ports) in comparison to the three ports with the most traffic.

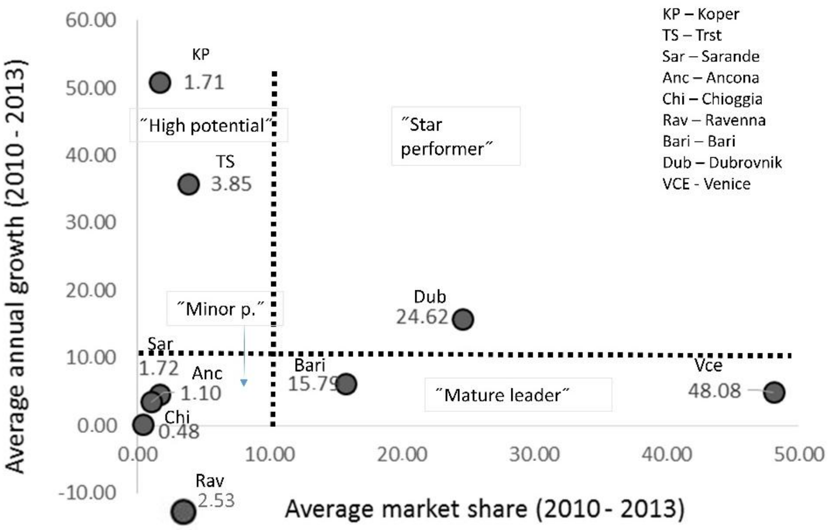

Fig. 5.
Port portfolio analysis
Source: Own calculations

It is important to note that the research was limited to the ports included within EA SEA-WAY project. Naturally, the position of the ports may change within the matrix if we included all the ports of the Adriatic-Ionian region; however, the matrix still represents a good overview of their competitive position and market share. The port of Venice clearly stands out from the rest of the ports with its position well into the ˝Mature leader˝ quadrant with almost 50% market share. This result is consistent with a similar study (Bagis and Dooms, 2014) among Mediterranean ports, which placed the port of Venice in the ˝star performer˝ quadrant for the period (2006-2011). The port of Bari is well situated in the mature leader quadrant with a steady market share and levelled passenger figures. Among the selected ports, only Dubrovnik is placed in the star performer quadrant. Its large market share, substantial average growth and the fact that it recently became a homeport, suggests that it will continue its trend of increasing passenger figures and further increase its market share. In the ˝High potential´ quadrant, Trieste stands out. Even though the port of Koper is situated in the same quadrant, the port of Trieste has greater potential to further its growth and strengthen its position in the quadrant and perhaps even move to the star performer quadrant due to its development as a hub/hybrid port. The minor performer quadrant is occupied by ports that are in various stages of their development with their futures unclear at this point.

3. Adriatic – Ionian Ferry sector

The geography of the Adriatic-Ionian region provides potential for the development of cross-sea ferry connections, especially from Italy towards Croatia, Montenegro, Albania and Greece, and for fast speed craft lines in the northern Adriatic; however, the majority of ports in the Adriatic-Ionian region have lost a number of ferry passengers in recent years (the trends are inconclusive and the drop in number of passengers is especially visible in 2013 in comparison to 2012).
There were around 17 million ferry passengers in 2013 in the Adriatic-Ionian region with the majority of them using domestic ferry lines in Croatia and Greece (Adopted from the Adriatic Sea Tourism Report 2014 (Turismo, 2014)).
As shown in Table 2 the most important country in regard to ferry traffic of the Adriatic-Ionian region was Croatia with almost half of the total passenger movements (7,874,264), despite the fact that it experienced only a 0.7% increase in the last year. Aside from Croatia, the only country that recorded a growth in the number of passengers was Greece (+5.3%).
These two countries have one important characteristic in common; they have a large number of island nearby, which makes for the right conditions for services. In the rest of the countries analyzed, the number of passengers in 2013 decreased. The exception was Slovenia, where the situation remained the same as in 2012, at a near negligible 156 calls per year.

Table 2
Non-cruise traffic by Country, Absolute values and Shares percentage, 2013

Ports	**2013**		**Share on total (%)**		**2012**		**Variation on 2012 (%)**	
Country	Pax. mov.	Calls	Pax. mov.	Calls	Pax. mov.	Calls	Pax. mov.	Calls
Croatia	7,874,264	43,961	46.4	54.2	7,822,238	43,252	0.7	1.6
Greece	4,798,663	27,984	28.3	34.4	4,556,500	28,688	5.3	-2.8
Italy	3,223,948	7,539	19.0	9.3	3,566,808	8,057	-9.6	-6.4
Albania	1,009,186	1,632	6.0	2	1,101,025	1,78	-8	-8
Montenegro	43,097	n.a	0.2	n.a.	53,259	n.a.	-19	n.a.
Slovenia	10,494	156	0.1	0.2	10,494	156	stable	stable
Bosnia-Herzegovina	0	0	0.0	0.0	0	0	0.0	0.0
Total 2013	16,959,652	81,182	100	100	17,110,324	81,935	-0.9	-0.9

Source: Adriatic Sea Tourism Report 2014

The number of ship calls decreased in total by 0.9% in 2013. The ports in almost all countries recorded fewer incoming ships than in 2012, with the exception of Croatia, whose number increased by 1.6% to reach 43,961 calls and, of course, Slovenia.
Figure 6 presents traffic shares regarding passenger movements and ship calls of ten major ferry ports in the Adriatic. The port of Split ranked first in 2013 with a 23.7% share, followed by Igoumenitsa and Zadar with 14.7% and 14.2% respectively. Those three ports accounted for more than 50% of all passenger movements in the Adriatic-Ionian region in 2013. The situation in the number of ship calls was different. The port with the largest share of ferry calls was Zadar (20.9%), followed by Corfu (18.7%), which in passenger movements reached only fourth place. The ports of Split and Igoumenitsa ranked third and fourth with 18.3% and 13.3% respectively. This means that the ports of Split and Igoumenitsa have been accepting larger ferry ships than the ports of Zadar and Corfu.

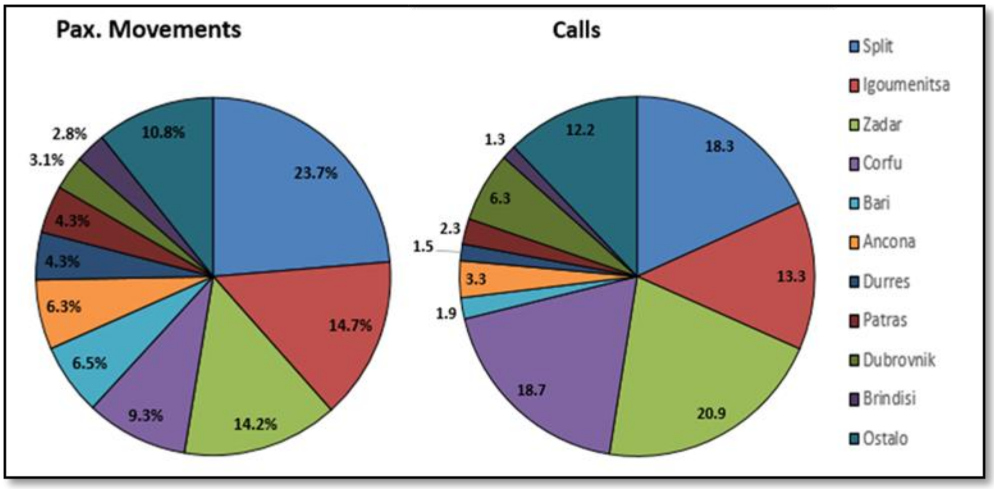

Fig. 6.
Traffic Share of the First 10 Ferry Destinations Among Adriatic Ports (2013)
Source: Adopted from the Adriatic Sea Tourism Report 2014

Further analysis of the ferry traffic in the Adriatic region includes ten ferry ports that were part of the EA SEA-WAY project.

3.1. Analysis of the selected ferry ports in the Adriatic-Ionian region

The study conducted within the EA SEA-WAY project included: the Albanian ports of Vlora, Saranda and Durres, the Greek port of Igoumenitsa, the Italian ports, Ancona, Bari, and Ravenna, the Croatian port of Dubrovnik, the Montenegrin port of Bar and the Slovenian port of Piran.
Among the analysed ports, Bari was the most successful in 2013 with 1,095,810 passengers, while the second and third place belonged to Ancona and Igoumenitsa with 1,064,562 and 900,975 passengers, respectively. By far, the least traffic was accounted for in Ravenna (4,996) (EA SEA WAY project data).

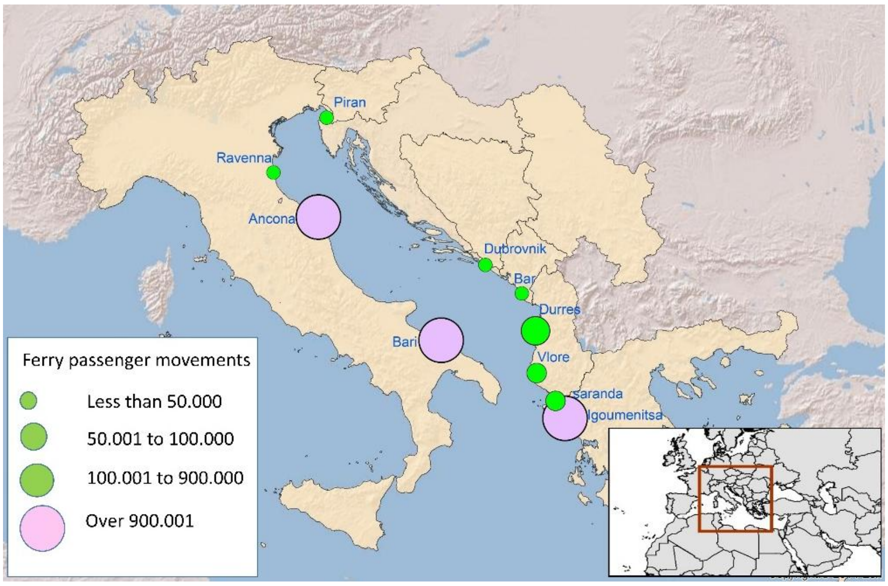

Fig. 7.
Ferry Passenger Movements, Adriatic-Ionian Region, 2013
Source: adopted from EA SEA WAY project data

Compared to 2012, the largest relative growth (17.7%) was recorded in the port of Saranda, followed by Igoumenitsa with 5.8%. Ancona traffic remained almost the same with a mere 0.2% growth. The largest drop in traffic was recorded in Bari at 21%, followed by Bar with an 18% drop, and Vlora with a 17% drop (EA SEA-WAY project data).
The new port of Igoumenitsa is one of the most important ports of the European Union as a category A port, which includes all ports of international importance. It is one of the biggest Ro-Ro ports of international transport in Greece and the eastern Mediterranean. The Port of Igoumenitsa is connected by ferry services to several ports in Italy, namely: Ancona, Bari, Brindisi, Ravenna, Trieste and Venice (Figure 8). The second largest, the port of Bari, is connected to some of the most important Adriatic ferry ports, such as Dubrovnik, Bar, Durrës, Corfu, Igoumenitsa, Patras and Sami. Ancona represents one of the busiest Adriatic ferry ports and is well connected by its port to many other locations. Destinations available from the port of Ancona include Split (with calls at Vis and Hvar), Zadar, Dubrovnik, Bar, Durres, Patras and Igoumenitsa (EA SEA WAY project data).

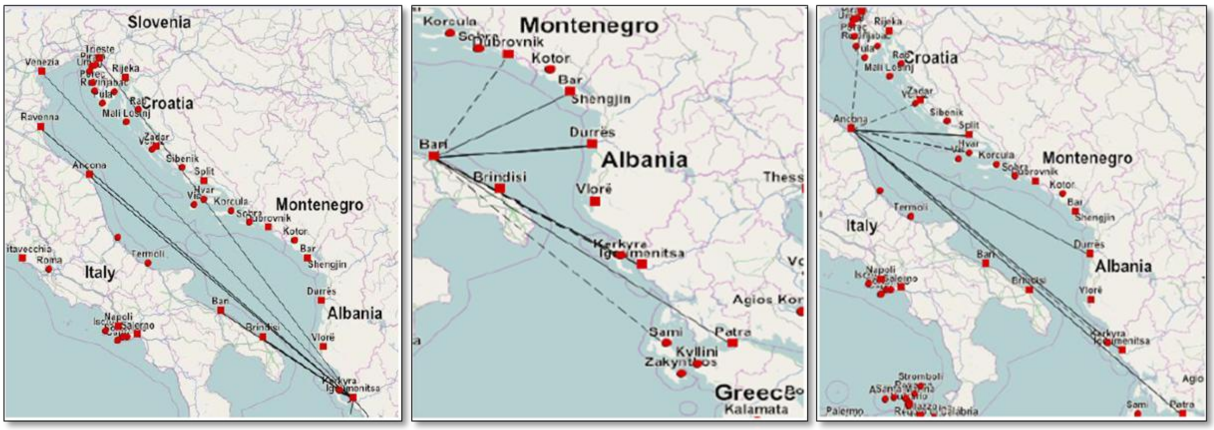

Fig. 8.
Ferry lines from the port of Igoumenitsa, Bari and Ancona
Source: (Ferry Lines, 2014)

The establishments of Ro-Pax ferry lines requires both ports to have adequate terminal capacities, including large parking areas, and terminal services offered to allow the pre-boarding and boarding procedures to be as fluid as possible and the stays of passengers within the port zones to be as pleasant as possible. In addition, the establishment of Ro-Pax ferry lines demands good hinterland connections to extend the catchment area of the service and in this way ensure sufficient demand.
In this segment, ports cannot expect significant progress in the future without good hinterland infrastructure. At this point, road transport is of the utmost importance for the functioning of ferry traffic flows in the Adriatic-Ionian region. Expressed flexibility and ability to quickly respond to modern transport demands have enabled the largest share of road transport at the level of the whole transport market. Although the majority of the Adriatic-Ionian ports are directly connected with railways and this represents a great opportunity for the seaports' competitiveness, the use of rail

transport by passengers is generally limited in the Adriatic-Ionian area, in particular with reference to long distance connections. Such a situation is in ever growing contradiction with the goals of EU integration and environmental sustainability. Apart from current limitations of transport demand, the main reasons for this situation are connected with various problems affecting western Balkans railways: limited size, fragmentation, aged infrastructure and rolling stock, and poor operating and financial performance.

3.2. Portfolio analysis of the selected Adriatic-Ionian ferry ports

The competitive position of ports within this study was, once again, determined using the ″port portfolio analysis″ method. The data used in this analysis was also gathered from the EA SEA-WAY project and port web sites. The time span for the observations was from 2010–2013, which may result in findings not being conclusive due to the short period so further observations are in order for the future verification of results.

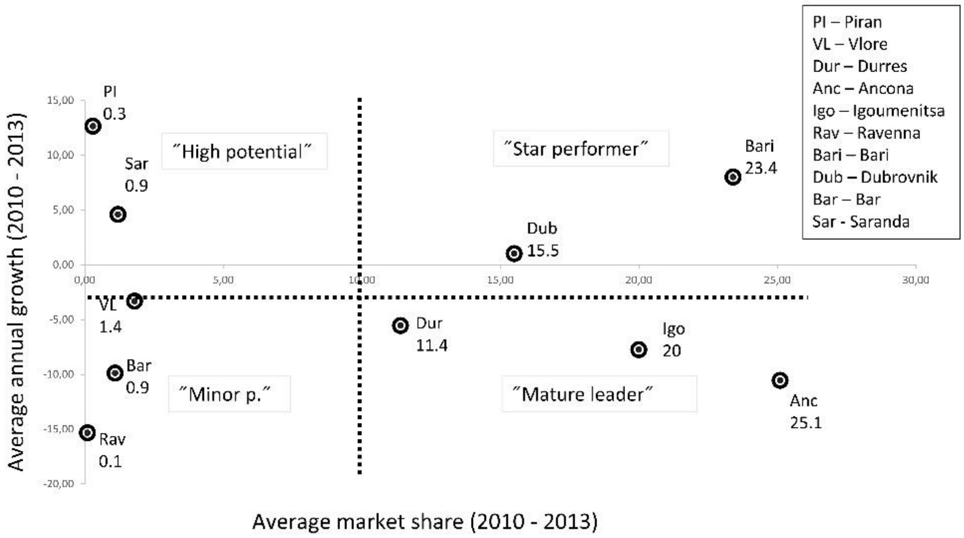

Fig. 9.
Ferry port portfolio analysis
Source: Own calculations

According to Eurostat (EUROSTAT, 2015), ferry passenger traffic in Europe was decreasing in the period from 2008 – 2011 by 11%. In the years 2010/11 the recorded traffic decrease was 4.2%. It was determined that this was the effect of construction of new bridges linking the mainland to islands, which caused many ferry lines to close. Most of the ports within this study continued the downward trend in the following time frame from 2010 onward.

Capturing the biggest and smallest ports of the area proved to be a challenge, since the study was limited to the ports included in the EA SEA-WAY project, but we have managed to show the traffic trends across the ferry traffic market.

The top three ports on our list were Igoumenitsa, Bari and Ancona, together taking a share of almost 70% of all traffic. Including the port of Dubrovnik, these ports take about 85% of all traffic among the ports included in the study. Even though the port of Ancona lost almost 30% of its traffic volume, it still retained over 25% of the market share with about 1.06 million passengers. Due to this drop in 2013, Bari had more traffic than Ancona, with almost 1.1 million passengers and was actually one of the few ports with increased traffic in the observed period.

Among all the ports in the study, only Igoumenitsa recorded significant traffic growth in 2013 (relative increase of +5.8%). Although the port of Piran recorded growth in the 2010 – 2012 timeframe (data for 2013 was not available), we cannot consider it as a high potential port as it is more of a marina than a port, with limited to no further development possibilities. The port of Sarande shows more potential for future growth; however, passenger figures in the observed period have been fluctuating a great deal, so it is impossible to say whether its growth trend will continue. The port of Durres, with over 10% market share, recorded an average 5.5% decrease of traffic from 2011-13 and is following the trend of the entire market, where the ports of Vlore, Bar and Ravenna are no exceptions with -3%, -10% and -15% decreases, respectively.

It will be interesting to see in the coming years whether the predictions of a more than 2% increase for the year 2014 in ferry traffic (Turismo, 2014) will actually be realised.

4. Conclusion

From the analysis, we can conclude that passenger seaborne traffic has a very important role in Europe. Predictions suggest that this sector will continue to grow in terms of ferry connections as well as the cruise sector, despite a certain decrease recorded recently. The European Commission plays a very important role in the promotion of seaborne transport. In recent years, it has significantly invested and supported not only the development of the Motorways of the Sea and Short Sea Shipping, but also ferry services and the development of modern cruising. The latter has now an increasingly important role in the world as well as in Europe. Among European regions, the Mediterranean definitely has a leading position in cruising sector, as it represents the second most important area for cruises in the world. The largest part of the cruise traffic is now taking place among the western Mediterranean ports, while Adriatic ports are gaining ever more importance. In the period from 2010 to 2013 the number of cruise passengers in this area increased by almost 25%. They have therefore high potentials to obtain an even greater share of Mediterranean traffic - as long as they know how to take proper advantage of the opportunities offered to them by the arrivals of an increasing number of ships in recent years. The ratio between the number of passenger movements and received ships shows that certain ports are gradually receiving larger ships that require greater port facilities as well as fast and efficient connections to the key tourist locations in the hinterland.

Through the performed portfolio analysis of the cruising ports in the period 2010 – 2013, we have been able to see that the ports with the largest growth are those, which have the best combination of criteria upon which the cruising companies select their homeports or ports of call. Based on those criteria Venice, Dubrovnik and Bari stand out. Almost all of the selected ports within this study recorded traffic growth in the observed period, indicating further growth in the cruise sector in the future.

The ferry sector lost a number of passengers in recent years (the trends are inconclusive and the drop in number of passengers was especially visible in 2013 in comparison to 2012), nevertheless predictions show that in the future there will be a growing demand for non-cruise passenger traffic in the Adriatic region. This means that as long as ports will want to continue their further development and increase mobility in the region, they will have to improve their inland connections.

However, the analysis in the ferry sector shows an overall decline in traffic in the past few years. Among the ports included in this research, Igoumenitsa, Bari and Ancona stand out in terms of market share, but among the three ports, only Bari recorded traffic growth in the observed time span (2010-2013). All of them recorded high fluctuations in traffic, so the trend is hard to determine. The most stabile traffic figures were recorded by Dubrovnik, which had a constant 1% increase. It will be interesting to see if the demand for non-cruise passenger traffic in the Adriatic region will turn upwards in the upcoming years.

ANALYSIS OF THE MAIN OPERATIONS AND THE CHARACTERISTICS OF THE ENVIRONMENTAL MATRIX AT THE ROMANIAN HARBORS IN THE BLACK SEA

Alina Modiga[1], Carmen Gasparotti[2], Liliana Rusu[3], Gabriel Popescu[4]
[1,2,4] *"Dunarea de Jos" Faculty of Naval Architecture, Dunarea de Jos University of Galati, Galati, Romania*
[3] *"Dunarea de Jos" Department of Mechanical Engineering, Dunarea de Jos University of Galati, Galati, Romania*

Abstract: The first objective of the present work is to present an overview of the main operations at the Romanian harbors in the Black Sea. The main harbors considered are Constanta, Navodari and Mangalia. First of all, it has to be noticed that the port activities in the target area were considerably enhanced in the last years. This is due to the considerable increase of the offshore activities in the western side of the Black Sea, as well as to the general enhancement of the human activities in the Romanian coastal environment and to the high dynamics of the economy grows in both nearshore and offshore areas. On the other hand, this implies also the coastal navigation of the river ships that are more exposed in the case of the harshest sea conditions. From this perspective, a second target of the proposed work is to analyze the main features of the environmental matrix in the vicinity of the harbor areas. For his reason, simulations with a wave modelling system, based on the spectral phase average model SWAN (acronym from Simulating Waves Nearshore), have been carried out for an extended time interval covering the 15-year period 1999-2013. The wind field considered for these simulations is that provided by NCEP-CFSR (United States National Centers for Environmental Prediction, Climate Forecast System Reanalysis) with a spatial resolution of 0.312º×0.312º and a temporal resolution of 3 hours. Moreover, in order to increase the accuracy of the wave predictions, some assimilation techniques of the satellite data, based on the Optimal Interpolation method, have been also implemented. Having as a basis this data set, a comprehensive picture of the wind and wave conditions in the vicinity of the main Romanian harbors has been provided.

Keywords: Black Sea, Romanian nearshore, harbor operations, environmental matrix, coastal hazards.

1. Introduction

The transportation has a very important role in every country's economy, since any product can be used only after it arrives, with the help of the transport means from the place of production to the use point. The transportation substantially contributes to attracting, in the economic circle, of the new territories, material and human resources and development of the foreign trade. The material resources are not evenly distributed on the globe, so it is necessary to be transported for long distances between different geographic areas of the world, by air, by rail, by road, inland waterway, by sea or by pipelines. The transportation requires a quarter of global consumption of fuel, one-third of electricity produced, 70% of rubber production, oils, metals and the others, so that it must be done in the most economical way.
Water transportation is used both within a country and also for the trade between countries of the same continent, or on the different continents (Ministry of Transport. Report on Master Plan on short, medium and long term of Romania transport).
The maritime transportation plays a crucial role in achieving of the movement of goods, both in terms of quantity and of the operability. This role is given by aspects such as relatively low cost, compared to the large volume of goods that can be transported, the complex and diverse nature of trade, the increasing of the number of participants in these exchanges.
The main elements underlying the definition of maritime transport are the following: the goods characterized by a large volume and high value, the ships as a means of transport and the ports as transshipment nodes and the facilities operating within them. It can be said that shipping is a particularly complex economic activity, having a national and international character, that must be conducted both after the needs and to ensure the profitability. The main function of maritime transport is to ensure the link between production and consumption and is characterized by two major features: economic efficiency and the profitability, involving the actual transport costs and the costs of the related operations (Rusu et al, 2014). These two features depend on the three elements that underlying of the definition of the shipping: goods, ships and ports.
The ports are the nodal points where large quantities of goods can be dispersed by destination on the various routes and by all means of transport (Ciortan, 2012). This is the reason of the water transport development of a country that should be placed in the context of the worldwide transport development and of the worldwide traffic intensifying of the goods. This is one of the most efficient means of transport, from the economic point of view, benefiting from the existence of the natural waterways. A particular importance for the transport is the commercial speed, which means the average speed of the way, including parking and for this indicator the maritime transport is situated on top of the hierarchy: 460-600 km/day, followed by transport by rail – 28-350km/day, and the inland transport – 150-200km/day (Ciortan, 2015).

2. Ports on the Black Sea

The Black Sea is an intercontinental sea located between southeast Europe and western Asia. Through the system of straits Bosporus- Dardanelles-Marmara Sea it communicates to the Mediterranean Sea and through the Kerch Strait with the Sea of Azov. It is bordered by the Pontic Mountains to the south and by the Caucasus Mountains to the east,

[1] Corresponding author: alina.modiga@ugal.ro

with a wide opening to the northwest. In the Black Sea there are numerous rivers that flow, such as: Danube, Dniester, Bug, Dnieper, Rioni, Kizil-Irmak and therefore its salinity is low (on average 20 to 22 o/00) compared to the planetary ocean. Many of these rivers are navigable, contributing to expanding the Black Sea hinterland.
The area of the Black Sea is about 411,540 km2, the maximum depth being about 2,212 m and the volume is 547,000 km3. Together with the Sea of Azov are bordered by six countries: Bulgaria, Georgia, Romania, Russia, Turkey, and Ukraine, and there are at least 35 harbors including 30 operating merchant seaports in the Black Sea. There are many important cities along the coast such as Batumi, Burgas, Constanța, Giresun, Hopa, Istanbul, Kerch, Mangalia, Năvodari, Novorossiysk, Odessa, Ordu, Poti, Rize, Sinop, Samsun, Sevastopol, Sochi, Sozopol, Sukhumi, Trabzon, Varna, Yalta and Zonguldak (Ports from the Black Sea and Danube). The harbors located in the Black Sea region are shown in Figure 1.

Fig. 1.
The maritime harbors on the Black Sea
Source: (https://commons.wikimedia.org/wiki/User:NormanEinstein)

The Romanian ports on the Black Sea are: Constanta, Midia Navodari and Mangalia. Development of the water transport in Romania was favored by the existence of over 200 km of coastline along the Black Sea and about 1,300 km of inland waterways. The Danube is one of the most important inland waterways in Europe, having a navigable length of 2,588 km from which 1,075 km run through Romania. To the benefits of this navigable potential were constructed 30 port facilities, as part of a transport integrated system. Some of these are of great complexity, integrated into the road, rail and air Romanian transport system. In this way it can be ensured the maritime connections with all the world's oceans, as well as the countries of Central and Western Europe. The Danube hinterland was substantially expanded through the channels Danube-Black Sea and Poarta-Alba-Midia-Navodari, which led to the development of a major traffic of goods, contributing significantly to the Romania's economic development. Thus, in Romania, in 2013 there were transported 317 million tons of goods including 76.4 million tons of goods on waterways (maritime - 44.48 million tons, inland navigation-26.62 million tons and 5.4 million tons via pipelines).

2.1. Issues identified in harbors

Constanta harbor has an outdated infrastructure that is inadequate for operating new flows of goods, including containers. Although it is an important harbor for container traffic, in 2013 have been operated only 661, 000 TEU compared to the peak year 2007 for the container traffic, when there were operated 1.41 million TEU. The current economic conditions, particularly the low fares paid for the container transport, have affected the shipping lines, which remained increasingly less to service the harbor and the platforms of common services arrive with containers for multiple shipping lines. It also requires the improving of the harbor connectivity.
The problems identified in the Constanta harbor are: old or undeveloped infrastructure, poor connectivity, the inability to operate new flows, capacity deficit (Raileanu et al, 2015).

2.2. Critical conditions for navigation

Shipping is a complex activity both by volume and nature of goods in traffic, but rather by specific operating conditions, seas and oceans imposing special measures for the safety of the ship.
In maritime transport people interact with technology, the environment and organizational factors, each of which having a determining role in the safety of the ship at sea (Gasparotti et al, 2014).
It admits that the production of accidents at sea is inevitable. There is a set of causes that lead to an accident. They consist of in high density traffic, unfavorable hydrometeorological conditions (storms, waves, rain, frost), navigation obstacles, conditions of the sea (sea depth and the topography of the seabed), reduced visibility, human errors, defects of the ship, fall out of gas in the tanks. These may individually or in combination lead to marine accidents (Gasparotti and Rusu, 2012).

It is widely accepted that marine accidents are not caused by a single cause, but a multitude of causes, including human factor, organizational and technological factors (Onea and Rusu, 2014a, b). Statistics show that most accidents occurred due to heavy hydro-meteorological conditions and human error. The most dramatic situations occur when these two factors are met, leading to loss of life, property damage and environmental pollution (Rusu and Guedes Soares, 2011).

In the Black Sea, the most accidents occurred during winter (November to March), when there are the worst hydro-meteorological conditions, strong wind, fog, heavy snow, low temperatures that produce ice on the deck and the superstructure of the ship affecting the buoyancy of the ship (Gasparotti and Rusu, 2014). In winter, the frequency of wind with high speeds is larger than the rest of the year. The winds with speeds of 11 and 15 m/s reach in winter 12-25% of all those present, and winds with speeds of 15 m/s reach to 10%, compared to the annual average of 3-5% (the characteristics of hydro-meteorological area of the Danube). Often the strong winds are accompanied by heavy precipitation, snowstorm and low visibility situations that can have lasting 13 to 45 days, that are accompanied by strong frosts increase the likelihood of marine disasters (Ivan et al, 2012).

3. Romanian ports on the Black Sea

Constanta Harbor The Constanța harbor is located on the western coast of the Black Sea, at 332 km from he Bosporus Strait and 157 km, from the Sulina Branch. The harbor has a favorable geographical position being connected with two Pan-European transport corridors: Corridor VII – Danube (inland waterway) and Corridor IV (railway). Together with the two satellite ports, Mangalia and Midia are part of the Romanian maritime port system. The Constanta harbor has a handling capacity of 100,000,000 tones per year and 156 berths, of which 140 berths are operational. It is divided into:
The *maritime harbor* has an annual operating capacity of 100 million tons and is serviced by 140 functional berths allowing access the ships with a capacity of 220,000 dwt.
The River port allows the access to any type of river ship having an annual handling capacity of 10 million tons. This port handles about 200 daily river ships.
The *tourist harbor* is a major milestone for passenger ships sailing along the Black Sea. Due to the total quay length of 29.8 kilometers with depths between 8 and 19 meters the Constanta harbor has become one of the most important European and international ports, allowing the accommodation of tankers with a capacity of 165,000 tonnes deadweight (dwt) and bulk carriers of 220,000 dwt. Constanța harbor is both a maritime and a river port, in which more than 200 river vessels/day are in the port for cargo loading or unloading. The Constanta harbor is connected with the Danube River through the Danube–Black Sea Canal, which represents one of the main strengths of Constanța Port. The cargo quantities are carried by river, between Constanta and Central and Eastern European countries, such as: Bulgaria, Serbia, Hungary, Austria, Slovakia and Germany.
The river traffic for the Constanța Port has had a share of 23.3% of the total traffic in 2005. The traffic started growing after 2003 and reached a record 61,838,000 tonnes and in 2008 there was the second largest cargo traffic in the history of the port. The most important terminals which are operational since 2004 there were: container terminal, passenger terminal, barge terminal and the oil terminal which has seven operational jetties that allow berthage for the ships up to 165,000 dwt capacity (National Institute of Statistics) (www.portofconstantza.com). In 2014 the Constanța harbor there were handled a total traffic of 55,641,910 tonnes of cargo and 668,293 twenty-foot equivalent units (TEU).
Mangalia Harbor Mangalia is a harbor for yachts and small boats up to 18 m long located on the Black Sea coast very close to the southern border with Bulgaria, at 38 km south of Constanta. It is the most modern tourist harbor in Romania, that covers 142.19 ha of which 27.47 ha is land and 114.72 ha is water. The harbor has the breakwaters with a total length of 2.74 km and 4 berths from which 2 are operational berths with a total length of 540 m. The maximum depth in the harbor is 9 m.
Midia Harbor The Port of Midia is located on the Black Sea coastline at 25.0 km north of Constanța, having breakwaters with a total length of 6.7 km. It covers 834 ha of which 234 ha is land and 600 ha is water and it has 14 berths from which 11 operational berths and three berths belong to Constanța Shipyard, with a total length of 2.24 km. The harbor depths are till 9 m at crude oil discharging berths 1–4, allowing access to tankers having a 8.5 m maximum draught and 20,000 dwt (www.portofconstantza.com).

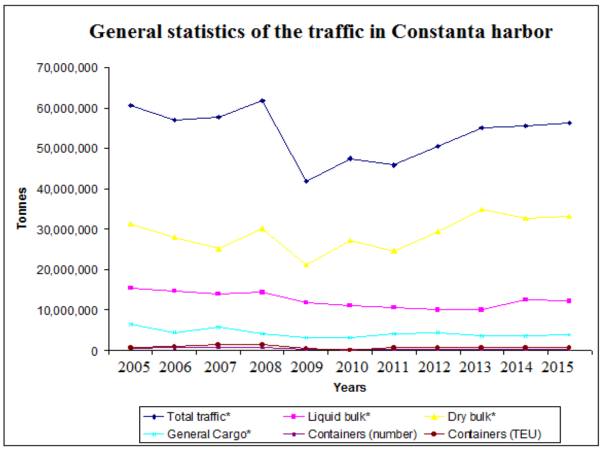

Fig. 2.
General statistics of the traffic in Constanta harbor

3.1. The main port operations

An accelerated growth of the world maritime traffic as a result of increasing the demand for raw materials and industrial products, has led to the diversification and specialization of the maritime transport and the increase of the ship's tonnage. Assuring of a wide range of services is essential to any port, and the satisfying of these requirements is an important factor for asserting on a "market harbors" that already exist worldwide. To become a modern port, the Constanta port was adapted to the needs of the transformation process of the international transport network providing a variety of services to everyone with who comes in contact: goods, ship, crew, port operators etc. (Vlasceanuet et al, 2015).
The seaports on the Black Sea ensure the optimal conditions for carrying out of all the activities of ships that coming into the port, such as: input and output, harboring when there are extreme weather conditions, the supplying and bunkering, the maintenance and repair and mainly the carrying out of all the port operations related to the exploitation during the shipping (Omer et al, 2015).
The main port public services that are provided, are: the pilotage of the ships at the entering and leaving the ports, as well as the handling from one berth to another; binding-unbinding the ships; the towing of the ships; the taking of the waste, sewage and garbage from ships; fire extinction from the ships and on the floating facilities located in ports; decontamination of the port waters and taking garbage from the economic agents operating in the ports. In the category of other services provided, are: loading/unloading, storage, handling, mooring, labeling, palletizing, expeditions national and international control services, goods, the rescue of the ships and the human life, repair of ships in the shipyards or outside, the international service of shipping and cargo etc. (www.portofconstantza.com).

3.2. Dynamics of the cargo traffic in the main harbors

The total goods traffic registered in the Romanian maritime harbors Constanța, Media and Mangalia was 32.71 million tons in the first seven months of 2016 in comparison with 33.41 million tones corresponding to the same period of 2015. On the other hand, the maritime traffic was of 25.64 million tons against 25.36 million tons at 31 July 2015, and the river traffic was 7.07 million tones, in comparison with 8.04 million tons at 31 July 2015.
In terms of transit goods through ports, the first place holds the cereals, followed by miscellaneous items, solid fuels and mineral oil products. The iron ore is ranked on the fifth place and are followed by non-ferrous ores and waste, chemicals and metal products and vegetables, fruits and cellulose are on the last places among the quantities of goods transited through Romanian ports.
The cargo traffic in the Constanta harbor is shown in Figure 3. The maritime traffic has had an ascending trend in the period 2009-2015 when it has increased in 2015 by 27.7% compared to 2009. The general statistics, calls of seagoing ships by capacity in the Constanta, Mangalia and Midia harbors are shown in Figure 4. In figure 4, it can be observed that calls of seagoing ships in all three harbors are the highest for the ship capacity until 5000 dtw.

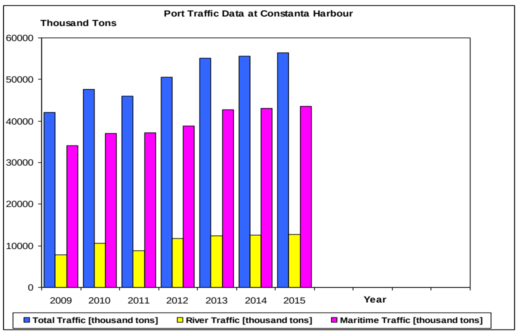

Fig. 3.
Port traffic data in Constanta harbor
Source: (www.portofconstantza.com.)

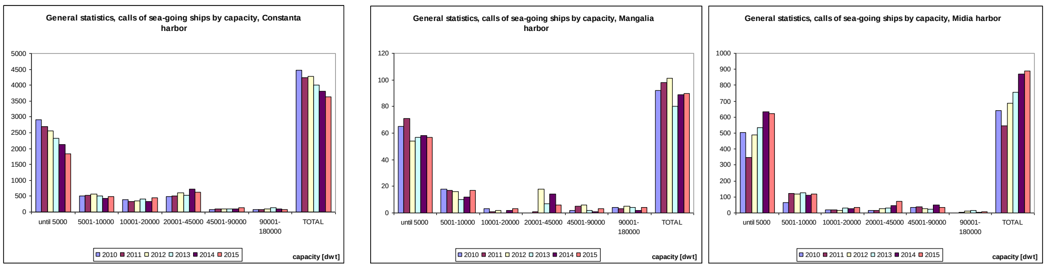

Fig. 4.
General statistics, calls of seagoing ships by capacity in Constanta, Mangalia and Sulina harbors, respectively.
Source: (www.portofconstantza.com)

4. Characteristics of the environmental matrix close to the harbor areas

In order to analyze the wave conditions in the vicinity of the main Romanian harbors a SWAN based wave modeling system was implemented and extensively tested in the Black Sea (see for example Rusu, 2010 and Rusu and Butunoiu, 2015). Moreover, this system was used to assess the extreme storm conditions along the Black Sea with the emphasis on the western side of the basin (Rusu et al., 2013). Further on, some data assimilation techniques have been also implemented in order to increase the accuracy of the model results.
For the present work simulations with this wave prediction system have been performed for the 15-year time interval 1999-2013 and, on this basis, an analysis of the most representative wave parameter (significant wave height - Hs) has been carried out. Thus, Fig. 5 illustrates the Hs histograms close to the main Romanian harbors. It can be noticed that close to the Constanta harbor, although most of the occurrences are in the range 0-1 meters, there exist however significant wave heights greater than 6 meters.

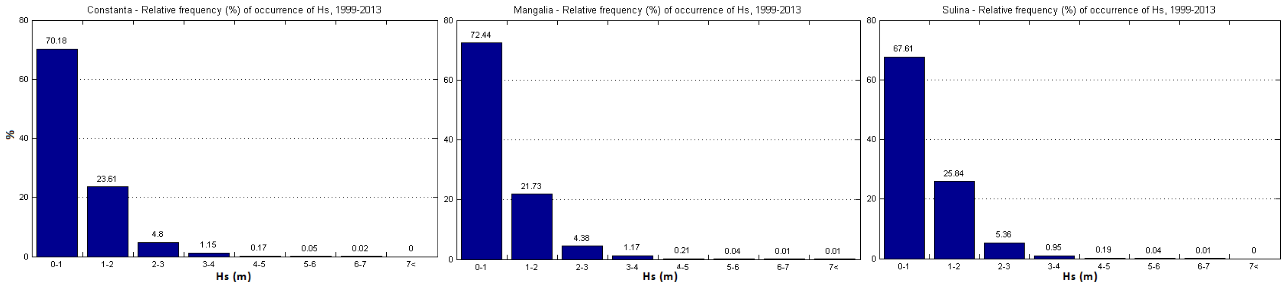

Fig. 5.
HS histograms close to Constanta (left panel), Mangalia (middle panel) and Sulina (right panel) harbors, respectively

The corresponding wave roses are presented in Fig. 6. As it can be seen, most of the waves are coming from North-Northeast, although the wave directions from South-Southeast are also representative. We can notice that close to Mangalia harbor there are waves with significant wave heights greater than seven meters, in a higher percentage than close to the harbors Constanta and Sulina.

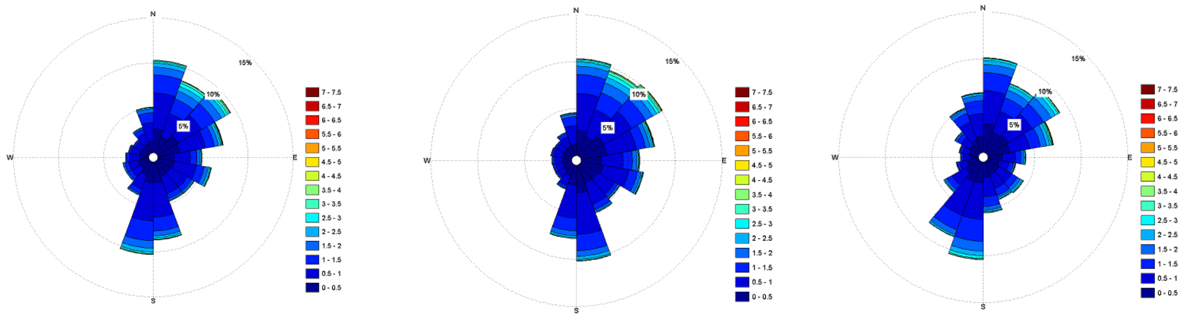

Fig. 6.
HS wave roses close to Constanta (left panel), Mangalia (middle panel) and Sulina (right panel) harbors, respectively

Looking at figures 5 and 6, it can be highlighted that the wave conditions close to the Romanian harbors at the Black Sea are very often quite strong and that is why an adequate knowledge of the main characteristics of the environmental matrix in the vicinity of the harbors (including also the extreme conditions that might be expected) represents an issue of crucial importance for the safety of the harbor operations.

5. Conclusions

The importance of the maritime transportation has determined the development of a broad international cooperation to ensure: avoiding the accidents and the organization of the assistance and the maritime rescue, the safety of life and ships at sea, the unification of legislation and methodology in the maritime transportation, the pollution prevention of the environment in general and of the marine environment in particularly, the protection of the ship-owners and cargo owners, the assurance of the goods, ships and people. Also, it is aimed to establish for the maritime trade, an appropriate legal and economic framework, equitable, sustainable and workable, amid international cooperation, guaranteeing functionality, equal rights and obligations of the partners. The first quarter of 2016 ended with a decrease of 7.8% of total freight traffic compared with the same period in 2015. The three ports of Constanta, Midia and Mangalia, were held together 12,907,895 tons, with 1,093,423 tons less compared to the first quarter of last year. At the negative result have contributed, mainly, the grain flows decrease by 35% and solid mineral fuels, by 27%.
Constanta port has performed 85.07% of cargo flows, while the Midia port only 14.50% and Mangalia port - 0.43%.

In terms of maritime traffic, this decreased by 4.04%, registering 10.22 million tons, and the river traffic was down by 19.76, reaching 2.68 million tons. In 2016 Constanta port has handled 10.981.333 tons of goods, down with 11.32%, or 1,401,965 tons compared to 2015. The grains and oilseeds continue to hold the largest share in total flows of goods, but this was reduced from 44.53% in 2015 at 32.40% in the first quarter of 2016. The container traffic in the port of Constanta has totaled 1,739,857 tonnes or 174 235 TEU, up by 9.18% and 10.43%, respectively, but remains well below the existing operating capacity.
The Midia harbor goes through a period of growth, recording a traffic of 1,872,242 tons, with 19.91% higher than the same period last year. The positive evolution was due to the quantities of oil and petroleum products larger with 31.46% and 4.60% respectively.
Mangalia harbor has performed only 54 320 tonnes, 4.09% below the level achieved in the first quarter of 2015.

ANALYSIS OF STABILITY OF PONTOON TYPE MARINE VEHICLE IN THE BAY OF VLORA

Kristofor Lapa[1], Blenard Xhaferaj[2]
[1,2] University "Ismail Qemali", Skele, Vlore, Albania

Abstract: Navigation safety is of particular importance especially on pontoon type marine vehicle that operate in specific areas. Pontoon is designed and built in the Pashaliman shipyard in Vlore in southwestern Albania. Its purpose is to supply the Albanian local fish farms with nutrients and it is designed to navigate within the bay of Vlora with a depth that goes up to 50 m. In order to be classified and get the navigation permission by the Albanian Shipping Register, the ship owner is asked to carry out the necessary technical documentation. Hydrostatic calculations and the verification of Stability Criteria are done with the help of Maxsurf package. Different situations are presented and analyzed in this paper by generalizing the respective conclusions.

Keywords: the bay of Vlora, MaxSurf software, ship stability, pontoon, marine vehicle.

1. Introduction

Fish farming sector is growing rapidly in Albania, mainly in the Gulf of Vlora. Small marine vessels are on increased demand in support of these farms. Pontoon vessel was built in the unique shipyard of Pashaliman and serves for communication with the farms for supplying food and obtaining fish from them. For this marine vehicle, after it was built, in order to guarantee navigation safety, it was requested from his owner the necessary documentation by the Maritime Register of Albania. With the help of technical drawings of the vehicle under construction and some other measurements made in pontoon after its construction, the modeling of pontoon in Maxsurf program was conducted and the verification of criteria was made for a secure stability in navigation.

2. 3D CAD modeling of the floating Pontoon hull

3D CAD modeling of the ship hull was made, after the shipyard made available for us the preliminary technical drawings of the initial project of the vehicle. The first step in building CAD model of this hull was to review the form of the hull. According to the preliminary design of the ship, it is a two-body vehicle with a distance of 0.5 m between them. Each of the semi-bodies is characterized by the fact that in a length of the hull of 12.25 m the transverse sections are unchanged. The sections in this length are transversal sections of the blade and an arising angle equal to 20^0. The bow body extends in a length of 1.45 m.
3D-CAD model was designed directly with the help of Maxsurf program, without the need to prebuild it in Prefit Program. The surface of the hull was designed by building first the surface of the demi-hull and then by duplicating this surface in order to take the final model of the pontoon hull. In the end all the surfaces were checked in order to respect the geometric boundary conditions.
The building of the 3D model of the ship hull was based on real measurements on preliminary technical drawing. Below are presented the main steps of CAD modeling process (Xhaferaj, 2008):

1. The necessary measurements in the preliminary technical drawing of the hull.
2. Modeling of each demi-hull surfaces by modeling individually each region of the hull (bow, stern, central body).
3. Union of individual surfaces modeled before taking the preliminary demi-hull form.
4. Checks of initial conditions of the designed demi-hull with geometry of the ship.
5. Smoothing of the surface of the CAD model of the demi hull.
6. Duplication of the demi hull in order to have the final form of the ship.
7. The drawing of the CAD model of the modeled hull is carried out.

Control points of the modeling hull surface in Maxsurf program have some limitations and their movement is needed to achieve a surface model without irregularities and to continue improving until reaching the optimal surface.
The obtained surface shown, in the following figures, seems to be a very good surface in respect of predetermined requirements. With the data obtained from the project and verification of measurements directly on the pontoon under construction, because of some deviations and modifications done during the construction process, by using the Maxsurf program, after a number of iterations, we obtained the final version of pontoon as shown in the following figures (Bentley, 2009), (Xhaferaj, 2010).

3. Evaluation of static and dynamic stability and verification of general and meteorological criteria of the pontoon type marine vehicle taken in the study

After receiving the acceptable version of 3D CAD form of Almarina pontoon hull, a series of calculations of hydrostatic and stability nature and the verification according the IMO regulations were carried out. Out of the comparison of these values relevant suggestions to the pontoon under construction were made, to be considered during its final construction and lunching to water.

3.1. Hydrostatic DATA

Hydrostatic data are calculated with the help of Maxsurf and Hydromax Software (Bentley, 2009), (Lapa, 2015), (Lapa, 2016). Here we present the data of the vessel with full load, that correspond waterline DWL=0.85m.

Table 1
Hydrostatic DATA of "ALMARINA" pontoon

Draft Amidships (m)	**0.800**	**0.900**			
Displacement (t)	37.37	44.25	Max Sect. area coeff. (Cm)	0.719	0.750

3.2. Stability DATA

Stability data are calculated with the help of Maxsurf and Hydromax Software (Bentley, 2009), (Lapa, 2015), (Lapa, 2016). Here we present only the diagram KN depending on displacement Δ for any heel angle φ. Also it is presented graphically the static stability curve of the hull in the right position of the ship taken in the study.

Table 2
KN in different heel angles of "ALMARINA" pontoon

Displacement (t)	KN in different heel angles									
	0	10	20	30	40	50	60	70	80	90

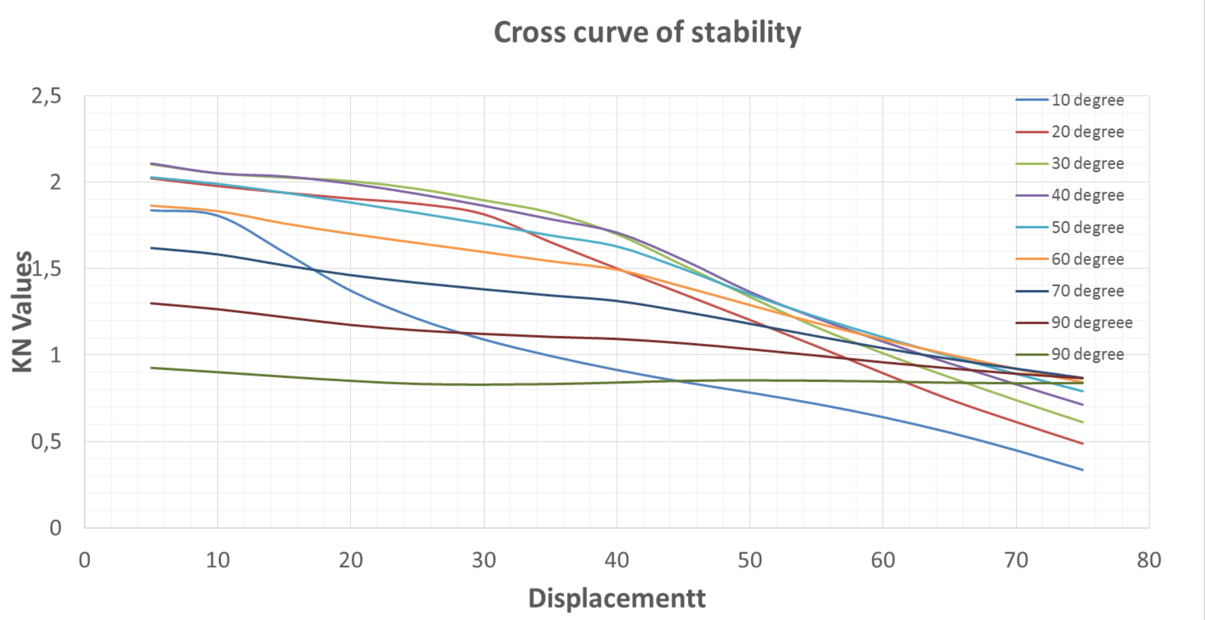

Fig. 6.
Graphic representation of Cross curve of stability
Source: Results taken by us in Maxsurf and Hydromax program and the graphic representation in Excel

3.3. Instruction to master for the use of cross curves of stability

The purpose of the cross curves is to enable Statical Stability Curves to be drawn (Bentley, 2009) for the ship in any sailing condition.
The righting lever can be calculated as follow:

$$GZ = KN - (KG \times \sin\varphi)$$

where:

- KN – Form Stability lever (see fig. 6)
- KG – Vertical position of center of gravity

φ - Angle of inclination

3.4. Calculation of the vertical center of gravity of the ship with 15 t cargo on main deck

Table 3
Weight Items and their vertical gravity center of "ALMARINA" pontoon (Lapa, 2003), (Lapa, 2004)

Nr	Weight Items	Weight (t)	VCG of weights Zi (m)	Moment about XY $M_{XY} = P*z$
1	Hull	17.341	0.5	8.6705
2	Crane	2	3	6
3	Crane engine	0.3	1.7	0.51
4	Crane basement	2	1.55	3.1
5	Planks of main deck	1.5	1.48	2.22
6	Main Engine	0.6	1.3	0.78

Vertical center of gravity of ship:

$$KG = \frac{\Sigma_2}{\Sigma_1} = \frac{49.5785}{39,341} = 1.26\ m$$

For the calculation of the ship's vertical center of gravity a weight of 75 kg is assumed for crew member. In this condition we have taken into consideration that the height of the cargo from the main deck does not exceed the value of 0.70m.

3.5. Stability data for 15 t cargo on the main deck

After drafting the diagram of stability for the pontoon type marine vehicle, it is necessary to verify the IMO criteria for stability and the results are shown in the following table:

Table 5
Verification of stability of the ship under IMO criteria of "ALMARINA" Pontoon (Bentley, 2009), (Lapa, 2004)

Code	Criteria	Value	Units	Actual	Status	Margin %
A.749(18) Ch3 - Design criteria applicable to all ships	3.1.2.1: Area 0 to 30	3,15	m.deg	24,17	Pass	+667
	3.1.2.1: Area 0 to 40	5,16	m.deg	34,27	Pass	+565
	3.1.2.1: Area 30 to 40	1,72	m.deg	10,10	Pass	+488
	3.1.2.2: Max GZ at 30 or greater	0,20	m	1,10	Pass	+446
	3.1.2.3: Angle of maximum GZ	25,00	deg	24,50 -25,50	Pass	+1,82
	3.1.2.4: Initial GMt	0,15	m	4,13	Pass	+2651

Source: Results taken by us in Maxsurf and Hydromax program

3.6. Weather criteria (wind and rolling criterion)

The ability of a ship to withstand the combined effects of beam wind and rolling shall be demonstrated with reference to the following figure and under these circumstances, area b shall be equal to or greater than area a,

$$\frac{S_b}{S_a} = 2.84 > 1$$

as indicated in the following figure below (Lapa, 2004), (Lapa, 2005):

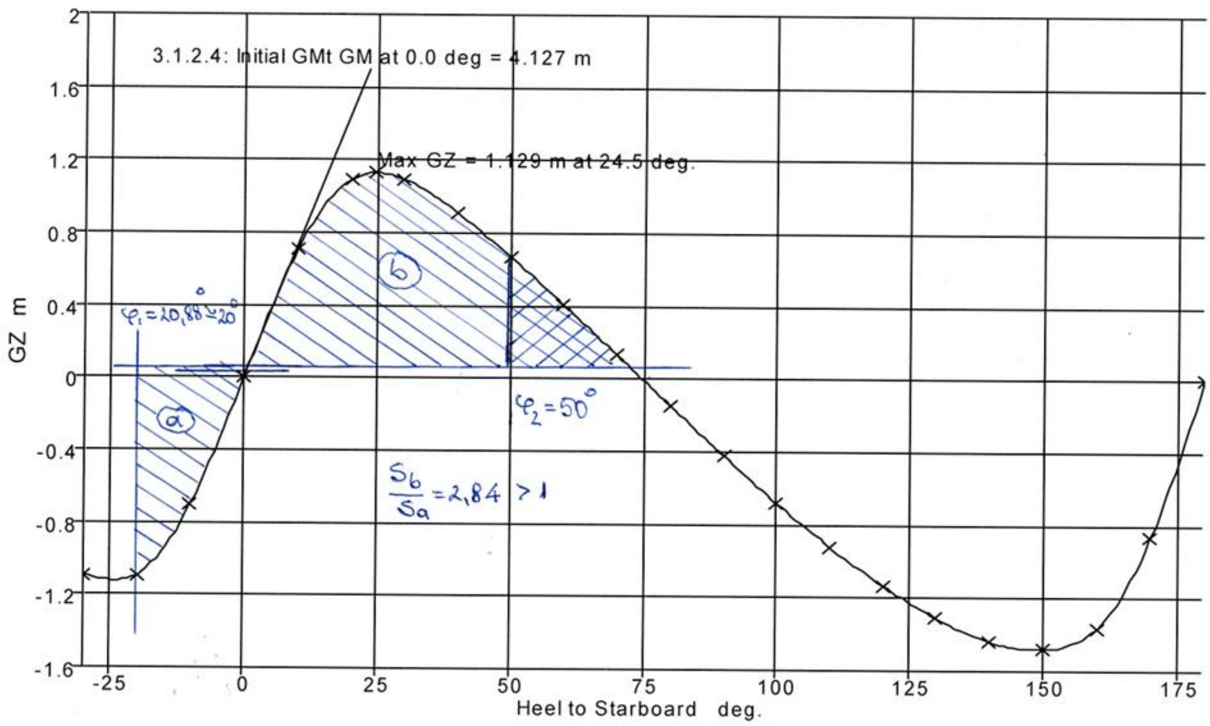

Fig. 8.
Severe wind and rolling
Source: Results taken by us

where the angles in this are defined as follows:

φ_0 = angle of heel under action of steady wind
φ_1 = angle of roll to windward due to wave action
φ_2 = angle of down-flooding or 50^0, whichever is less,

The wind heeling levers Iw1 and Iw2 are constant values at all angles of inclination and shall be calculated as follows:

$$I_{w1} = \frac{P \cdot A \cdot Z}{1000 \cdot 9.81 \cdot \Delta} = \frac{0.504 \cdot 22.204 \cdot 0.972}{1000 \cdot 9.81 \cdot 39{,}341} = 0.0281 m$$

where:

P = wind pressure of 504 Pa.

A = projected lateral area of the portion of the ship and deck cargo above the waterline = 22,204 (m^2)

Z = vertical distance from the center of A to the center of the underwater lateral area or approximately to a point at one half the mean draught =0.972 (m)

Δ = displacement = 39,341 (t)

g = gravitational acceleration of 9.81 m/s^2.

$$I_{W2} = 1.5 \cdot I_{W1} = 1.5 \cdot 0.0281 = 0.042m$$

The angle of roll (φ_1) shall be calculated as follows:

$$\varphi_1 = 109k \cdot X_1 \cdot X_2 \cdot (r \cdot s)^{0.5} = 109 \cdot 1 \cdot 0.80 \cdot 0.75 \cdot (1.019 \cdot 0.1)^{0.5} = 20.88^0$$

4. Conclusion

The marine vehicle pontoon type ALMARINA was built in the shipyard of Pashaliman.

Calculations were made for the completion of necessary technical documentation at Albanian Shipping Register after the pontoon was built.

It is shown that IMO stability criteria are fulfilled with an increased rate of stability, with the exception of GZ_{max} value.

The full procedure is indicated for stability calculations of the pontoon combined with the data obtained from drawings and verifications by direct measurements and the help of computer programs.

Maxsurf packages once again show its credibility in carrying out these calculations.

The results obtained may also serve to further studies and assessments related to this type of floating Pontoon type or in other similar cases.

CARGO CONTAINERISATION AND ITS IMPACT ON THE DEVELOPMENT OF MARITIME TRANSPORT

Andrej Dávid[1], Peter Piala[2], Vlatka Stupalo[3]

[1,2] Department of Water Transport, University of Žilina, Žilina, Slovakia
[3] Department of Water Transport, University of Zagreb, Zagreb, Croatia

Abstract: Cargo containerization belongs to the most significant changes that happened in maritime transport in the 20th century. Containers not only reduce loading time in sea ports; but they also help to protect cargo against its damage, loss and theft. The first commercial transport of containers was carried out 60 years ago. In April 1956 the Ideal X, the converted tanker from the Second World War, transported them on her deck along the East Coast of the USA. Nowadays different types of containers are transported by cellular container ships which are divided into the generations according to their dimensions and transport capacity. In maritime transport there are three main container trade routes which link the developed to developing countries located in Asia, Europe and America. Sea ports are the gateways for all kind of cargoes which are transported by ships between the continents. In the world there are about 400 sea ports which transship containers in their container terminals. Twenty top world container ports transship about 50 % of a whole container port throughout the world. Most of them are located in Asia. Handling devices of terminals move and handle containers; they also transship them between different means of transport before they are forwarded to their final destination. Container terminals differ from one another in the way that they handle equipment and systems. Some of them have used the innovation technologies to increase their throughput such as automated handling equipment, double or triple spreaders.

Keywords: cargo containerization, containers, vessels.

1. Introduction

Throughout history, maritime transport has always played an important role in cargo transport between the continents. Cargo transport has been speeded up as the result of cargo containerization since the1950s. Nowadays, most general cargoes are transported into these transport units. Before the launching of containerization, most cargoes had been carried by port workers on dry cargo vessels which had transported them to other sea ports. The basic goal of the paper is to focus on the changes which have happened in maritime transport as the result of cargo containerization, such as the construction of vessels, maritime canals, container terminals, their handling equipment and systems.

2. The Status Quo of Maritime Transport and Containers

2.1. The Main Container Trade Routes

In maritime transport, there are three main container trade routes: the Transatlantic, Transpacific, and Europe – Asia (Figure 1). They link the developed to developing countries in the world and enable cargo exchange.
The first regular container transport started between North America and Europe in the mid-1960s (Stopford, M.). Local war conflicts in the world, world economic crises, piracy or the movement of subsidiaries of transnational companies from developed to developing countries may cause the changes in the direction or the volume of transport flows.

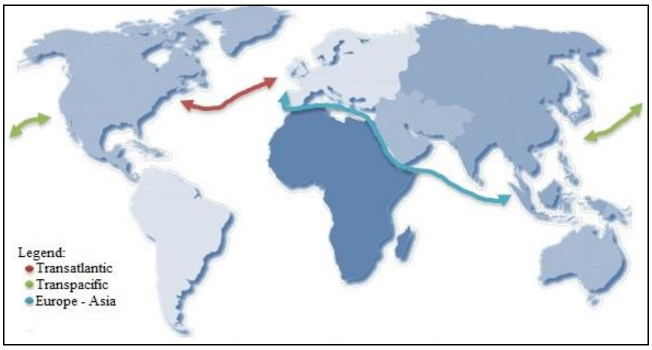

Fig. 1.
The main container trade routes
Source: authors

In 2014 most containers were transported between Europe and Asia (Table 1). Import to Europe was about 15.4 million TEUs, while export from Europe was about 7.0 million TEUs. On the container trade routes, significant imbalances have existed in export and import of containers which may influence on the prize for transport. In the same year, import of containers from North America to Asia (Transpacific route) was 14.7 million TEUs, while export was only 33.8 %

[1] Corresponding author: andrej.david@fpedas.uniza.sk

(7.5 million TEUs). The least amount of containers was transported between North America and Europe. (Review of Maritime Transport 2015)

Table 1
Transport of containers on the main container trade routes between 2012 and 2014 (estimated numbers)

year	Transatlantic		Europe – Asia		Transpacific	
	Asia to North America	North America to Asia	Asia to Europe	Europe to Asia	Europe to North America	North America to Europe
2012	13,1	6,9	13,7	6,3	3,6	2,7
2013	13,8	7,9	14,3	6,9	3,6	2,7
2014	14,7	7,5	15,4	7,0	3,9	2,7

2.2. Top 20 World Container Ports

Nowadays there are approximately 400 world container ports that handle containers; the top 60 ports handle about 98 per cent of world container port throughput. Many countries have only one or two major container ports servicing the deep-sea trades, which are supported by a range of smaller ports handling short-sea and distribution trade. (Stopford, M.), (Grobarcikova, A., Sosedova, J.)
In 2014, the top 20 world container ports handled about 45.7 per cent of world container port throughput. It was about 310.116 million TEUs. These ports showed a 4.5 per cent increase in throughput compared to 2013. Between the top 20 world container ports there were sixteen Asian ports, three European ports and one American port. The port of Shanghai which was the world´s busiest container port was followed by Singapore and Shenzhen. The port of Rotterdam was the busiest European sea port; the port of Hamburg and the port of Antwerp followed it. In America, the port of Los Angeles was the busiest port. (Review of Maritime Transport 2015), (Jagelčák, J., Dávid, A., Rožek, P.), (Gašparík, J., Abramović, B., Halas, M.), (Mašek, J. et al.)

Fig. 2.
The busiest container ports in the world
Source: Port of Rotterdam

2.3. The Container Ships and their Development

Containers are transported by container vessels which are divided into generations according to their transport capacity and dimensions.
The first container ships appeared in the USA in the 1950s. Converted tankers from WWII transported containers on deck along the East Coast of the USA. In that time there was no special handling equipment that moved containers between vessels and sea ports. All handling operations were carried out by onboard or port cranes.
Due to the increase of cargo which was transported into containers, the second generation of container ships started to be built about a decade later. In the mid-1960s, these vessels started transporting containers between the East Coast of the USA and Western Europe. The last of them were cellular containers ships. Since then, each hold has had vertical rails called cell guides. In the hold containers can be stacked vertically. Depending on the size of the ship, they may be stacked up to 9 tiers below deck.
In the 1970s, shipyards started building another generation of container ships called Panamax. It was the last generation of container ships which could pass through old generation of lock chambers of the Panama Canal. The size limit of these locks chambers, which were built at the beginning of the 20th century by the USA, influenced on the dimensions of Panamax. Their deadweight was about 65 thousand tons. They could carry from 1 700 to 3 000 TEUs, out of which 8 tiers of containers below deck and up to 13 rows of containers on deck. The containers are handled between the vessel and the terminal by Panamax container gantry cranes. Their outreach is at least 35 meters.

Fig. 3.
Panamax Container Ship in the port of Koper
Source: Authors

The fourth generation of container ships, Post Panamax, was built in the 1980s, but could not pass through the Panama Canal due to their dimensions. Ships that used to transport containers between the Atlantic and the Pacific Ocean had to sail around Cape Horn. They could carry from 3 000 to 6 000 TEUs, out of which up to 9 tiers of containers below deck and 16 rows and up to 7 tiers of containers on deck. The outreach of Post Panamax gantry cranes which serve vessels is at least 45 metres.
In the 1990s, the fifth generation of container ships, called Super Post Panamax, started to be built. The vessels of this generation can only enter the ports which have deep water due to their draught. (Záležák, M.)
Ultra large container ships have been built since 2005. They may carry more than 9 000 TEUs (generally 12 – 14 000 TEUs). The length of ships is over 350 m, the draught is 14 – 15 metres, and they may transport 22 or 23 rows of containers and up to 7 tiers on deck. Their average speed is between 23 and 25 knots (40 – 50 kilometres per hour). The maximal seaward overhang of container gantry cranes that serve these vessels is at least 60 metres. (Široky, J.)

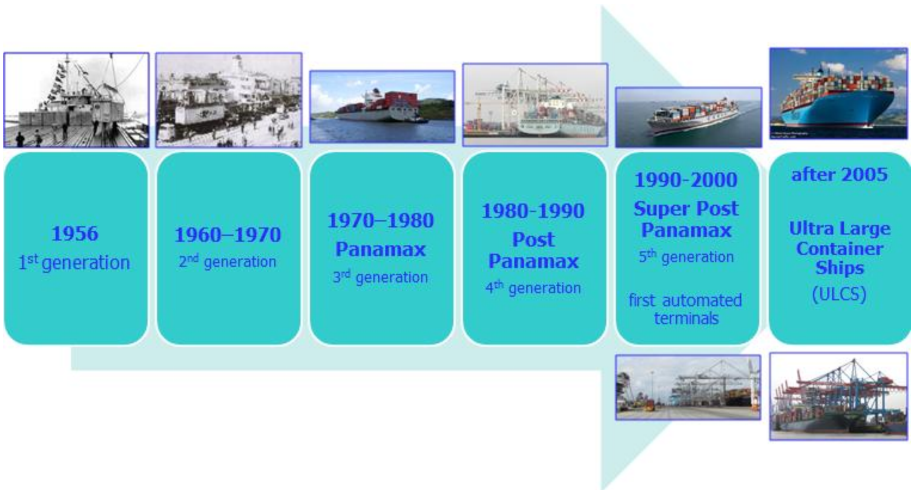

Fig. 4.
The development of container ships and terminals
Source: Authors

2.4. The Strategic Maritime Canals and Straits

In maritime transport there are several strategic canals and straits that are important for maritime transport.
The Panama Canal, which is located in Panama, shortens the distance between the Atlantic and the Pacific Oceans in about 7 000 – 9 000 miles. It is about 80 km long and was opened for maritime transport on 14 August 1914.
The Panama Canal has been managed by Panama since 1999. Nowadays between 13 and 14 thousand of vessels pass through the Canal every year which carry about 300 million tons of cargoes. Most of these vessels come from the USA and China.
In 2006 Panama decided to expand the Panama Canal because of the increase of its throughput. In 2015 new generations of lock chambers with reutilization basins were completed on both sides of the Canal. A new generation of container ships, New Panamax, has been able to sail through the Canal since 26 June 2016. These ships are much bigger and can carry more containers than Panamax. (Panama Canal Authority)
The Suez Canal provides a much shorter route between the North Atlantic and the Indian Ocean than the alternative route round the Cape of Good Hope. It links the Mediterranean Sea at Port Said with the Red Sea at Suez. The Canal,

which is the longest canal without locks in the world, is approximately 193 km long. It was opened for international navigation in 1869 after 10 years of construction.
The term Suezmax is used for ships that can sail through the Canal. Their deadweight is from 125 thousand to 240 thousand tons and their maximal width is 46 metres. Since its opening in 1869 it has been closed twice because of two war conflicts: the Suez Crisis (1956 - 1957) and the Six Day War (1967-1975). During its closing, tankers had to sail around the Cape of Good Hope and shipyards started building ultra large crude carriers.
The Suez Canal has been managed by Egypt since its nationalization between 1956 and 1957. (Suez Canal Authority)
The Kiel Canal connects the river Elbe at Brunsbüttel (the North Sea) with Kiel Fjord at Kiel-Holtenau (the Baltic Sea). It shortens the distance between the North Sea and the Baltic about 250 miles than the alternative route round the Jutland Peninsula. This canal is very important for feeder vessels that carry cargo between the port of Hamburg and the Scandinavian or Baltic States. Its length is about 98 km and has got two lock chambers. (Kiel Canal)
The Strait of Malacca belongs to the busiest and the most important waterways in the world. It links the Indian Ocean and the South China Sea and runs between Sumatra Inland and the Peninsula of Malaysia. Over 50,000 vessels (container vessels, tankers and bulk carriers) pass through the Strait per year, which transport raw materials such as coal, iron ore to manufacturing areas in Southeast and Northeast Asia. About a quarter of all oil carried by sea passes through the strait, mainly from the suppliers of the Persian Gulf to Asian markets such as China, Japan, and South Korea. The Strait is about 500 miles (800 km) long but it is very narrow and shallow. The term Malaccamax is used for ships which can sail through the Strait of Malacca. The limitation for these vessels is their draught. The Strait of Malacca belongs to the most vulnerable places in maritime transport due to attacks of pirates. (Široký, J.)

2.5. Container terminals and its basic parts

Container terminals are facilities where containers are loaded, unloaded, handled and transferred by different types of container handling equipment between different means of transport. They are also stored in an open-air storage area for a few days before they are forwarded by sea or land transport to their customers. (Tsinker, G.)
The land of the container terminal may be divided into three parts: the water side transfer area, the container yard and the land side transfer area.
The water side transfer area is the land of the container terminal from the wharf to the container yard. It is equipped by Post Panamax or Super Post Panamax container gantry cranes which transfer containers between a ship and the terminal. The different means of equipment (tractor with semi-trailer and truck trailer, straddle carrier, reach stackers, AGVs) transport containers between the water side transfer area and the container yard
The container yard is used for storage of containers which takes between 3 and 5 days (Agershou, H.). It is divided into the blocks that are located perpendicular or parallel to the wharf. Each block is equipped by at least two automated gantry cranes on rails that move containers within the block of yard or between the block and other parts of the terminal. The terminals that do not use automated handling equipment have got the blocks of container yard located parallel to the wharf. The blocks are equipped by gantry cranes on tyres which do the same function as automated gantry cranes on rails in the automated container terminals. Their advantage is that they may move from one block to another.
In the land side transfer area containers are transferred between means of road and rail transport by rail mounted gantry cranes. Wagons or tractors with semi-trailers transport containers between the terminal and the hinterland.

2.5.1. Handling equipment of container terminals

Container handling equipment can be divided into two categories:
1. Equipment that moves containers between the vessel and the terminal such as gantry container cranes. These cranes belong to the most widespread equipment in the world container sea ports. They can serve specialized container vessels that anchor at the wharf.
2. Equipment that moves containers within the terminal. Different types of equipment are used for handling containers within the terminal. Straddle carriers, automated guided vehicles or tractors towing trailers transfer containers between the wharf and the container yard. Within the terminal straddle carriers, rubber-tired or rail-mounted gantry cranes can carry out stacking or unstacking of containers. Tractor-trailer systems may be involved in receipt-delivery operations. (Tsinker, G.)

2.6. Automated container terminals

Automated container terminals are terminals in which some container handling equipment operates without direct human interaction. Drivers of the cranes have been physically removed, or they have remained in their cabins, but they are not needed for the entire duty cycle (Port of Los Angeles Automated Container Terminal Survey).
These terminals use some automated handling equipment such as automated guided vehicles, different automated stacking cranes or automated straddle carriers that:

- Transport containers at the water side transfer area from the wharf and to the container yard (automated guided vehicles, automated straddle carriers),

- Move containers between the water side transfer area and the container yard, the container yard and the land side transfer area and within the blocks of the container yard (different automated stacking cranes, automated straddle carriers),
- Transfer containers at the railway station located at the land side transfer area between semi-trailers and wagons (rail-mounted gantry cranes).

Automated container terminals differ one from another in reference to their level of automation, the type of handling equipment and system. Some of them use only automated handling equipment at container yards (Total Terminal International in the port of Algeciras). Automated stacking cranes (automated rail-mounted gantry cranes or rubber-tired gantry cranes) move and stack containers into the blocks of container yards. They also transfer containers between handling equipment that is located at the water or land side transfer area and the container yard.
More modern automated container terminals also use automated handling equipment at the water and land side transfer area (Container Terminal Altenwerder in the port of Hamburg). Automated guided vehicles or automated straddle carriers that are located at the water side transfer area transport containers between the wharf and the blocks of container yards. Automated / semi-automated stacking cranes that are located at the railway station at the land side transfer area, transfer containers between means of transport such as road and railway transport.

Fig. 5.
Automated Container Terminal Altenwerder in the port of Hamburg
Source: Authors

2.7. New ways of increasing throughput in the world container ports

The throughput belongs to the most significant indicators of world container ports. It is defined as the maximal volume of containers which is transferred by handling equipment of port between different means of transport for the monitoring period. It depends on technical equipment of sea port, transhipment technology, the type of containers, dimensions of container vessels, and other means of transport. (Záležák, M.)
The throughput is reduced by different downtimes that arise during transhipment of containers. These downtimes follow from the breakdown rate of handling equipment, their technical breaks and auxiliary operations related to vessels such as anchoring and cargo inspection.
The world container ports have used different methods to increase their throughput:

1. The increase in the number of container gantry cranes (cranes) which serve container ships. This system was used in the container terminal Ceres located in Amsterdam. The cranes located on both side of the basin used to transfer containers between a vessel and the terminal. According to the calculation transhipment was reduced to about 50 %,
2. Automation of handling processes. This system has been used in the world container ports more than 20 years. ECT Delta Terminal located in the port of Rotterdam was the first terminal in the world that started using automated guided vehicles at water side transfer area. Automated stacking cranes, automated guided vehicles and automated straddle carriers have replaced handling devices controlled by port operators. Their movement within the terminal is controlled by port computers (Kolarovszki, P. 2016. et al.),
3. The increase in the number of containers that are transhipped in an operating cycle. The first container gantry cranes used to tranship the only one container in an operating cycle. Nowadays, some cranes can handle from 2 to 6 TEUs or from 1 to 3 FEUs in an operating cycle. They use double or triple twin-lift spreaders. They can be found in some Asian ports such us the port of Shenzhen or the port of Dubai. Some container gantry cranes use two trolleys. The first trolley (water side trolley) tranships containers between a container and the platform

which is located inside of the portal of crane. The second trolley (land side trolley) handles containers between the platform and the apron. Loading / unloading time is reduced about 30 and 40 per cent.

3. Conclusion

The basic goal of the paper was to focus on the changes which have happened in maritime transport as the result of cargo containerization. On one hand these changes have influenced the construction of faster and bigger container ships which enable to transport at least 10 thousand TEUs per journey between the continents, on the other hand they have also affected on the widening of the dimensions of maritime canals and straits. The increased turnover of containers in the world container ports in the last few years has caused the changes in the construction of container terminals, their handling equipment and systems. Some world container ports are building the automated container terminals which will be equipped by the latest generation of container gantry cranes and other automated handling equipment. On one hand, this automated handling equipment will enable faster handling operations in the container terminals which will influence the throughput of container terminals; on the other hand, they will reduce the amount of time that the vessels spend at the ports and the staff costs of ports workers including the costs for transshipment operations.

THE STATUS OF VESSELS FOR SPORT AND RECREATION IN THE CROATIAN AND MONTENEGRIN LEGISLATION AND MEETING THE REQUIREMENTS OF NAVIGATION SAFETY IN NAUTICAL TOURISM PORTS

Ranka Petrinović[1],Nikola Mandić[2], Ena Sirišćević[3]
[1,2] Faculty of Maritime Studies, University of Split, Split, Croatia
[3] Faculty of Law, University of Split, Split, Croatia

Abstract: Nautical tourism on the Adriatic Sea represents a particularly significant sector of maritime and tourist activities. The safety of sport and pleasure boats guarantees successful performance of nautical tourism activities. An increasing number of these boats sailing in the Adriatic Sea is important for the overall economic development of the Republic of Croatia and the Republic of Montenegro. In Croatia, sport and pleasure boats are regulated by the Maritime Code, the Ordinance on Boats and Yachts and a number of subordinate legislation acts, while in Montenegro they are regulated by the Law on Yachts, the Law on Safety of Maritime Navigation, the Regulation on Boats and other subordinate legislation. These regulations govern the conditions for navigation, the area of navigation, seaworthiness of yachts and boats, procedure and conditions for acquiring qualifications and certificates for boat leaders, yacht masters and skippers. This paper puts special emphasis on regulatory laws on yachts, sport and pleasure boats, as well as on requirements that must be met in ensuring the safety of navigation. According to the broadest definition, a yacht is a boat designed and equipped for long sea voyages, and it is used for sport and pleasure. However, more detailed analysis indicates inconsistency in legislative terminology of the two systems, such as the definition of the term "yacht". The same applies to the term "boat". It can therefore be concluded that there are certain differences in the Croatian and Montenegrin legislation, and in this respect the paper will also provide *de lege ferenda* solutions.

Keywords: sport and pleasure boats, yachts, sailing vessels, nautical tourism, nautical tourism ports, safety of navigation.

1. Introduction

The Adriatic Sea is a bay deeply cut into the mainland of the Mediterranean between the Balkan and the Apennine peninsulas stretching in the south-east and north-east directions. It occupies an area of 138,595 km^2. The total length of coastline (mainland and islands) is 7912 km, and the indentation coefficient is 6.1. A part of the eastern Adriatic coast from the mouth of the river Dragonja to the middle of the entrance to the Bay of Kotor belongs to the Republic of Croatia, and the part of the coast from the middle of the entrance to the Bay of Kotor to the mouth of the river Bojana belongs to Montenegro.

Highly developed coast of Croatia is 5,835 km long, which is 74% of the total length of the Adriatic coast. There are 1,244 islands, islets and rocks and 4,398 km of the coastline length estimate belongs to the coastline of islands. The indentation coefficient of the Croatian coast is 11, which makes it one of the most indented coasts in the world. The total length of the Montenegrin coast is 260 km, which represents 3.3% of the total length of the Adriatic coast. Number of islands, islets and reefs is 48. The coefficient of indentation of the Montenegrin coast is 3. The surface area of the Croatian part of the Adriatic sea is 31,067 km^2, and of the Montenegrin part is 2099 km^2.

The Adriatic Sea affects a way of life which is very similar among the inhabitants of the coastal areas of Croatia, Montenegro, Italy and Albania. Regardless of the length of the coast, Croatian and Montenegrin coasts are considered to be very suitable for nautical tourism, a part of industry that contributes significantly to the economic development of both countries. Nautical tourism is a form of tourism with distinctive features which significantly distinguish it from other forms of tourism, and particularly because of the models of management of maritime domain and navigation safety systems at sea.

Nautical tourism means navigation and accommodation of tourists – navigators on cruising vessels and in nautical ports for the purpose of rest and recreation. Although nautical tourism is an integral part of the tourist industry, it is a highly interdisciplinary phenomenon and therefore, we can say that nautical tourism is an interdisciplinary tourist phenomenon containing a maritime component. (Luković et al., 2015) The essential difference between nautical tourism and other forms of tourism is in sailing and great mobility of nautical tourists, which involves frequent and often daily change of residence.

The positive effects of nautical tourism are of great importance in the development of the economy, not only for obvious economic effects, but also the fact that tourist consumption contributes considerably to the growth of relatively small national markets of Croatia and Montenegro enabling, so-called, *invisible exports*. In addition to all positive effects of nautical tourism there are negative ones which are reflected primarily in the use of external environment for infrastructure development, as well as short seasonal presence of a large number of tourists in a particular area and the increased number of sailing vessels, which enhances the number of maritime accidents during the summer months (*Development Strategy of Croatian Nautical Tourism*).

2. Nautical tourism legislation

As stated at the beginning, nautical tourism is a part of the tourist industry with a significant maritime component. (Luković et al., 2015) In nautical tourism, tourist services are mainly provided in the ports of nautical tourism and on board nautical tourism vessels. The nautical tourism ports and waterborne craft are classified into types, and certain types are categorized. Different kinds of subordinate legislation govern the types and categories of nautical tourism ports and vessels, the minimum requirements to be met by such ports, as well as the categories and methods of categorization of ports and vessels of nautical tourism.
In Croatia, nautical tourism activities are governed by several laws and regulations. Two basic legal regulations are *the Maritime Code* and the *Act on the Provision of Tourism Services.* Apart from those, it is necessary to point out *the Maritime Domain and Seaports Act.* Subordinate legislation governing nautical tourism includes *the Ordinance on Boats and Yachts, the Ordinance on the Classification and Categorization of Nautical Tourism*, the *Ordinance on the Types and Categories of Vessels of Nautical Tourism, the Ordinance on the Conditions to be met by Vessels, and Natural or Legal Person Performing the Activity of Leasing Vessels, the Regulation on Conditions for Leasing Vessels with or without Crew and Offering Accommodation Service on board Vessels*, *the Regulation on the Classification of Ports Open for Public Transport and Ports for Special Use*, *the Decree on Conditions that Ports Must Meet* and *the Regulation on Conditions for the Arrival and Stay of Foreign Yachts and Boats Intended for Sport and Leisure in the Internal waters and Territorial Sea of the Republic of Croatia*.
In Montenegro activities in nautical tourism are also regulated by several laws and regulations. The main statutory requirements are *the Law on Yachts, Port Law, the Law on Maritime Domain, the Law of the Sea, the Law for the Prevention of Pollution from Ships and the Law on Safety of Maritime Navigation.* Subordinate legislation governing nautical tourism includes *Regulation on smaller boats, Regulation on Conditions that must be met by Ports Classified according to the type of Maritime Traffic* and *Purpose* and *the Decision* on *Determination of Ports according* to *Significance.*

3. Categorisation of ports and vessels of nautical tourism

As previously stated, the two basic components that make up the nautical tourism are the nautical tourism ports and nautical tourism vessels.

3.1. Nautical tourism ports

3.1.1. Croatia

According to Art. 2, para. 1, pt. 1 of *Maritime Domain and Seaports Act*, in the broadest sense, a port shall mean a seaport, i.e. water space and the land space with developed and undeveloped coast directly connected with sea space, as well as breakwaters, installations, plants and other facilities designed for landing, anchoring and protection of ships, yachts and carrier boats, embarkation and disembarkation of passengers, loading and unloading of goods, storage and other handling of goods, manufacturing, refinement and finishing of goods, as well as other economic activities in economic, traffic and technological relation with these activities.
Furthermore, according to their purpose, ports are divided into ports open for public transport and ports for special use. Both types of ports can be ports open for international transport and ports open for domestic transport. According to the activities carried out by the ports for special use they can be divided into: naval ports, nautical tourism ports, industrial ports, shipbuilding ports, as well as sports, fishing and other type of ports for similar purposes. By their importance for the Republic of Croatia, the special purpose ports are divided into: ports of importance for the Republic of Croatia, and ports of county importance.
Nautical tourism activities take place in the ports for special use primarily nautical tourism ports and ports intended for sports. A nautical port mainly serves for reception and accommodation of cruising vessels and it is equipped for provision of services to clients and vessels. From business, construction and functional aspects, it makes an integral whole. Nautical tourism ports are functional business units in which a legal or natural entity operates and provides tourist services in nautical tourism and other services in the area of tourist spending (trade, catering, etc.). Accordingly, the ports of nautical tourism are tourist facilities in which, apart from communication services, a variety of other additional services are provided, such as accommodation and catering for boaters, maintenance and repair of vessels, supply of spare parts, food and hygiene products supply, and recreational and all other services that navigators need. (Šamanović, 2002) Sports ports are ports used for berthing of sailing vessels registered in the Croatian Register of sailing vessels intended for sport and leisure, and owned by association members, or by the same association which has a concession contract for the port.
Nautical ports of importance for the Republic of Croatia are those that have a capacity of 200 berths and more, and those of importance to a county are the ones that have a capacity of up to 200 berths in the sea. Sports ports of importance for the Republic of Croatia are those that have a capacity of 200 berths and more, and of importance to a county are those that have a capacity of up to 200 berths.

Reception facilities for sailing vessels are located in nautical tourism ports and at nautical berths in the ports open to public transport. Nautical berths can be a year-round, seasonal and transit. Receiving capacity is on a year-round and seasonal basis. Boat reception services include leasing of permanent and transit berths.
The Regulation on Classification and Categorization of Ports for Nautical Tourism prescribes the types, minimum requirements, categories and method of categorization of nautical tourism ports. Nautical ports, according to the type of services they provide in the port, are divided into: anchorage, cruising boat storage, dry marinas and marinas. *Anchorage* is a part of the sea or water area suitable for anchoring of sailing vessels, equipped with equipment for safe anchoring. *Storage of sailing vessels* is a part of the land fenced and equipped for rendering services of sailing vessels storage on land, and the provision of services of transport of boats, their launching and taking out of the sea. This type of *Storage of sailing vessels* does not provide accommodation for tourists and it is not used for preparing sailing vessels for their voyages. *Dry marina* is an area fenced and arranged for providing the storage of sailing vessels on dry land and they also provide the services for their transport, launching and taking out of the sea. A *dry marina* type can offer accommodation to tourists, as well as services for preparing sailing vessels for their voyages. *Marina* is a part of water and shore area specially built and equipped for providing services of communication, accommodation of tourists on board sailing vessels and other services.
Marinas are the only type of nautical tourism ports that are categorized. The category of marina depends on the fulfilment of the conditions laid down for each category in the *The Regulation on Classification and Categorization of Ports for Nautical Tourism*: quality of equipment and facilities, standard of basic services, diversity of additional services offered to tourists at the marina, as well as other services and facilities at disposal to tourists in the immediate vicinity of the marina and the quality of maintenance of the marina as a whole. Marinas are awarded anchors for each category. They can have: two, three, four or five anchors.

3.1.2. Montenegro

According to Art. 4, par. 1, pt. 5 of *Law on ports*, a port is defined as the sea and a shore area directly connected to the sea with constructed and non constructed quays, piers, breakwaters, buildings, installations and facilities intended for the provision of port services and performance of other activities regarding the economic, traffic or technological matters. Furthermore, according to their purpose, ports can be divided into: commercial ports, nautical tourism ports - marinas, shipbuilding ports and fishing ports. According to the types of maritime transport, ports are divided into ports open for international and for domestic transport.
According to their significance, ports are divided into ports of national significance and ports of local significance. *The Decision* on *Determination* of *Ports according* to *Significance* individually determines the ports of national and of local significance.
The nautical tourism activities take place in the ports of nautical tourism - marinas. *Nautical tourism ports - marinas* are ports intended for accommodation, storage, protection, maintenance, repair, fitting out and mooring of yachts and smaller boats.
The Rulebook on Types of Nautical Tourism Facilities, Minimal Technical Conditions and their Categorization classifies the reception facilities of nautical tourism and divides them into marinas, ports and harbours, docks, berths and anchorages. *A marina* is the nautical tourism facility with naturally or artificially protected water (sea, lake and river) areas, specializing in providing communication, supply, storage, maintenance and repair of sailing vessels, catering services, boat rental services, as well as other services in accordance with the requirements and the specific needs of nautical tourists. *Ports, harbours and docks* area nautical tourism facilities that are wholly or partly designed and tailored specifically to the primary navigation needs of the nautical tourism sailing vessels (reception, berth and supply), as well as other basic living and service needs of nautical tourists (inspection and minor repairs on sailing vessels). *Berths* are specially constructed coast or the coast connected areas fitted out for reception and berthing of nautical tourism sailing vessels, with direct pedestrian access to the vessel. *Anchorages* are naturally or artificially protected sea, lake or river water area furnished and equipped with mooring gear for nautical tourism boats, without the possibility of pedestrian approach to the boat.
Of all nautical tourism reception facilities only marinas are subject to categorization. Marinas are classified according to the conditions that must be met regarding their design, equipment and types of services (mandatory elements), and other conditions and facilities at their disposal (optional elements). The classification of marinas into categories and category designation is done in a way that each single category is symbolically awarded a suitable number of boat propellers: five propellers are awarded to the first category marina, four propellers to the second category marina, three propellers to the third category marina, two propellers to the fourth category marina, and one propeller to the fifth category marina.

3.1.3. Comparative analysis

Contrary to classification of ports of nautical tourism in Croatia prescribed in *The Regulation on Classification and Categorization of Ports for Nautical Tourism,* in the publications on nautical ports, (anchorages, boat storages, dry marinas and marinas) are divided into anchorages, berths, dry marinas and marinas. Such a division is contained in *The Regulation on Classification and Categorization of Ports for Nautical Tourism* of 1999, which expired after adopting the new *Regulation* in 2008. However, the new *Regulation* in its transitional and final provisions stipulates that legal or natural persons who on the date of entry into force of the *Regulation*, have a trade license for the port of nautical tourism in accordance with the *Regulation* of 1999, are not obliged to align with the new *Regulation*, but they may apply for classification and categorization in accordance with the new *Regulation* of 2008. According to this provision, the most of nautical tourism ports are still categorized by the previously valid categorization. Therefore, the classification that is provided in the new *Regulation* of 2008 has not yet taken hold in practice. However, this fact is not damaging considering the vagueness that has been brought by the new *Regulation* of 2008. Instead of "berth" that *Regulation* cites "boat storage" which is by definition very similar to a dry marina. In fact, the only difference being that the boat storage is used for the storage of sailing vessels on land where tourists cannot stay, and where it is not possible to prepare the boats for navigation, while in dry marina it is possible for the tourists to store their sailing vessels, stay there, and prepare their sailing vessels for navigation. The above shows that there is no essential difference between the definitions of these two terms. The difference is not sufficiently significant to mean specific types of nautical tourism ports, and therefore, this division is unnecessary. Although the new *Regulation* of 2008 tries to distinguish between the two, we believe that this is unnecessary and impracticable. Thus, it has been proposed to amend this part of *the Regulation on the Classification and Categorization of Ports for Nautical Tourism* and to restore the categorization as in *the Regulation* of 1999.

The analysis of Montenegrin *Rulebook on types of nautical tourism facilities, minimal technical conditions and their categorization* shows a lack of precision in defining the harbours, docks and berths, and their classification criteria are not clear. Namely, in the division itself, harbours (together with ports) are listed separately from the docks, and where each term is being defined there is a combined definition for both, *harbour* and *dock*. Although in practice there might be reasons for distinguishing these concepts, they are not adequately highlighted in *the Regulation*. Furthermore, there is no mention of differences between *marinas* and *dry marinas*, which certainly needs to be mentioned with regard to the specific protection of the sailing vessels on land. Therefore, we believe it is necessary to adopt a new division, or amend the current one in a way that each type of reception facility for nautical tourism is adequately defined.

Legal regulation of marinas, which still are the most important part of nautical tourism, has been adjusted in an adequate manner in both countries. We may just point out that in the categorization of marinas, there are differences because Croatia categorizes marinas in four, and Montenegro in five categories. However, this does not seem to make a significant difference.

3.2. Vessels

In nautical tourism there are numerous vessels of different properties and uses. Cruise ships are included in nautical tourism vessels. However, these vessels are not the subject of analysis in this article.

The common feature of all vessels in nautical tourism is that they are intended for sport and recreation. In principle, the vessels in nautical tourism are not subject to the provisions of international conventions, but are subject to local regulations as far as the safety of navigation is concerned. Therefore, it is necessary to separately analyze the Croatian and Montenegrin regulations that conceptually define vessels in nautical tourism.

3.2.1. Croatia

According to Art. 5 of the *Maritime Code*, as the basic regulation in the domain of maritime law, vessels shall be classified as ships, warships, submarines, yachts and boats. Due to the specifics of nautical tourism it is necessary to highlight the concepts of ships, boats and yachts. *Ship* is a waterborne craft designed for sea navigation, 12 meters in length and a gross tonnage of more than 15 tons, or it is authorized to carry more than 12 passengers. *Yacht* is a waterborne craft for sports and recreation, regardless of whether it is used for personal needs or business, exceeding 12 m in length and intended for a longer stay at sea, which is furthermore authorised to carry no more than 12 passengers in addition to the crew. *Boat* is a waterborne craft intended for navigation at sea, which is not a ship or a yacht, and the length of which is more than 2.5 metres or the total power of its propulsion engines is greater than 5 kW. The term boat does not encompass: vessels belonging to another maritime craft for the purpose of collecting, salvaging or conducting work, vessels intended exclusively for competitions, canoes, kayaks, gondolas and pedal boats, windsurfing boards and surfboards. If the Maritime Code does not provide otherwise, its provisions relating to ships also apply to yachts.

According to the *Ordinance on Boats and Yachts* there is a more detailed classification of vessels in nautical tourism, based on the technological characteristics of the vessel. Therefore, we have boats for personal use, boats for commercial purposes, yachts for commercial purposes, yachts for personal purposes, pleasure boats and speedboats. *Boat for personal use* is a boat for sport and leisure that is not used for commercial purposes, while *boat for commercial purposes* is a boat for transport of passengers and / or freight against payment, recreational boats for leasing, professional fishing, extraction of gravel, stone and other economic activities. *Yacht for commercial purposes* is a yacht designed for leasing with or without crew, while *yacht for personal needs* is a yacht that is not used for commercial purposes. *Pleasure boat* is a vessel of any type intended for sports and leisure that has a hull length from 2.5 to 24 m measured according to agreed standards, regardless of the type of propulsion. *Speedboat* is a boat or a yacht that slides on the surface of the sea using a mechanical propulsion device.

According to the *Ordinance on the Types and Categories of Vessels of Nautical Tourism* a vessel of nautical tourism is a ship, a boat or a yacht designed and equipped to provide tourist services in nautical tourism. Furthermore, the same *Ordinance* states that the vessels of nautical tourism shall be classified according to the type of services they provide:

craft for excursions and cruising craft. *Craft for excursions* is intended for tourist transport services for excursions lasting up to 24 hours without accommodation services. *Cruising craft* is intended for tourist transport services of cruising lasting over 24 hours, equipped for days-long stays of tourists. The craft must meet the minimum requirements established by specific regulations regarding registration in the Croatian Register, as well as the conditions prescribed by the *Ordinance*.

Every year when processing the data on the capacity and operation of the nautical tourism ports, Croatian Central Bureau of Statistics divides the vessels for leisure and sports into yachts (motor and sailboats) and other vessels. *Motor yacht* is a vessel equipped with engine intended for leisure, sport or recreation, which is according to common maritime customs, equipped with a cabin with at least two beds, a toilet and cooking facilities. *Sailboat* is a vessel intended for leisure, sport or recreation whose main power is wind. It is equipped with a cabin with at least two beds, a toilet and cooking facilities. *Other vessels* are boats (wooden, plastic, rubber, etc.) of 3 meters or more in length, or less than 3 meters if they have an engine. Speedboats are also included into *other vessels* unless they qualify for yachts.

3.2.2. Montenegro

Article 2 of *the Law on Yachts*, provides definitions for yachts, foreign yachts, foreign smaller boats, yachts for economic activity and yachts for personal use. *Yacht* is a vessel driven by engine or sail power, which can have more than one hull, designed and equipped for days-long stay at sea for pleasure, sport and recreation. It is over 7 meters in length, and it is used for personal needs or economic activities. *Foreign yacht* means a yacht flying a foreign flag. *Foreign smaller boat* is a vessel that has a foreign flag. *Yacht for economic activity* is a yacht, or a foreign yacht intended for leasing with or without crew. *Yacht for personal use* is a yacht or a foreign yacht that is not used for economic activities. This regulation does not fully define the terms since it does not give the definition of *smaller boat*, and states that the foreign smaller boat is a craft with a foreign flag. Therefore, with regard to *the Law on Yachts*, the full meaning of the term "smaller boat" is unclear.

The Law of the Sea defines, among other terms, the terms *ship* and *foreign yacht*. *Ship* is a vessel designed for sea navigation, 12 meters in length and a gross tonnage of more than 15 tons, or it is fit to carry more than 12 passengers. *Foreign yacht* is a vessel that has a foreign flag, 7 meters in length, used for leisure, sport and recreation and is suitable for days-long stay at sea.

Article 6 of *the Law on Safety of Maritime Navigation* defines the terms: *ship, boat, smaller boat and yacht*. *Ship* is a vessel designed for navigation (passenger, cargo, technical craft, fishing, public or scientific research ships), whose length is more than 12 meters and a gross tonnage more than 15 tons, or carrying more than 12 passengers. *Boat* is a vessel designed for sea navigation, 7-12 meters in length and a gross tonnage of less than 15 tons with power of less than 75 kW and fit for days-long stay at sea. *Smaller boat* is a vessel designed for navigation at sea, which is neither a boat nor a yacht, whose length is more than 2.5 meters, with engine power greater than 5 kW, including the watercraft, jet-ski , etc. In addition to the lifeboats on the vessel and smaller boats for sport competitions (canoes, kayaks, gondolas and pedal boats, surfboards and windsurfing boards) and it is not fit for days-long stay at sea. *Yacht* is a vessel intended for leisure, sport and recreation, more than 7 meters in length, which is not engaged in international navigation.

In Article 2 of the *Regulation on Smaller Boats*, the terms defined, among others, are a *smaller marine boat, smaller boat for commercial purposes, smaller boat for personal needs, speedboat, smaller sails boat, and smaller rowing boat*. *Smaller marine boat* is a craft intended for navigation at sea, with less than 12 meters in length, and registered capacity of less than 15 gross tons. *Smaller boat for commercial purposes* is a boat for the transport of passengers and / or goods against payment, fishing, extraction of gravel, stone etc. *Smaller boat for personal needs* is a boat for leisure, sport and other non-economic purposes. *Speedboat* is any boat that uses a mechanical drive device to slide on the surface of the water. *Smaller sails boat* is any boat that uses sails with sufficient surface size to move through the water. *Smaller rowing boat* is any boat which is propelled by oars.

The Rulebook on Types of Nautical Tourism Facilities, Minimal Technical Conditions and their Categorization classifies the vessels in nautical tourism and divides them into recreational craft, excursion craft, tourist yachts and tourist craft for tourist cruises. *Recreational craft* is a craft that is propelled by human power, wind or engine, used for pleasure and sports and recreation on the local reception facility of nautical tourism (smaller boat, a boat with an engine, sailing boat, water bike, surfboards, water scooter etc.). *Excursion craft* is a smaller boat or a ship used to transport tourists or day cruises with excursion facilities (hydrofoil, a smaller boat with an engine or a smaller ship for day trips, tourist taxi). *Tourist yacht* is a vessel for a longer stay of boaters at sea, with a cabin equipped with at least two beds, a toilet and cooking facilities (engine-powered yacht, wind-powered yacht). *Craft for tourist cruises* is a vessel with a crew that carries tourists for sailing and cruising, and is equipped for longer stays of crew and tourists at sea.

Yachts and craft for tourist cruises are nautical tourism vessels that are subject to categorization. Nautical tourism vessels are categorized according to the conditions in terms of design, equipment and types of services they provide (mandatory elements), and other conditions and facilities at their disposal (optional items). Classifying vessels of nautical tourism into categories and category designation is done in a way that each single category is symbolically awarded suitable number of ship propellers (screws): tourist yachts / craft for tourist cruises of the first category - three ship propellers, tourist yachts / craft for tourist cruises of the second category – two ship propellers, tourist yachts / craft for tourist cruises of the third category - one ship propeller.

3.2.3. Comparative analysis

From the aspect of safety of nautical tourism vessels, the *Maritime Code and the Ordinance on Boats and Yachts* are the most important regulations in Croatia. Their terminology should be the norm of all the other regulations and official documents. However, after examining the report of the Central Bureau of Statistics, it can be seen that the terminology used does not comply with these regulations. That is, the phrase *other vessels* includes boats of up to 3 meters in length or more, or of less than 3 meters if they have engines. Maritime legislation does not recognise the term *smaller boat* (cro. čamac), but instead, uses the term *boat* (cro. brodica) which is limited to 2.5 meters in length. By analyzing the data from the report of the Central Bureau of Statistics, it is not possible to obtain the actual facts on the types of nautical tourism vessels, and that, somehow causes the terminological ambiguity. We, therefore, believe that it is necessary to align the terminology of the Central Bureau of Statistics with the definitions of *the Maritime Code* and *the Ordinance on Boats and Yachts*.

By analyzing the definitions of vessels in nautical tourism used in various regulations in Montenegro, we can see that there is even greater inconsistency in determining the terms, and overlapping of the definitions of certain types of vessels. In *the Law on Yachts*, for example, there is the definition of *smaller foreign boat* as a vessel that has a foreign flag, and in fact, the very term of the *smaller boat* has not been defined. On the other hand, the same *Law* defines the terms *yacht* and *foreign yacht*. Thus, it can be interpreted that a smaller boat is any vessel that is not a yacht, which is not the case in any way.

Therefore, *in the Law on Yachts* it is necessary to define the general term *smaller boat* before defining the term *smaller foreign boat*. *The Law on Safety of Maritime Navigation* is less ambiguous as it includes the definitions of the terms: *ship, boat, smaller boat and yacht*. According to it, *boat* is a vessel intended for navigation, 7-12 meters in length, and a gross tonnage of less than 15 tons, with power of less than 75 kW. *Smaller boat* is a vessel intended for navigation at sea, which is neither a boat nor a yacht, whose length is over 2.5 meters, or engine power greater than 5 kW, while *yacht* is a vessel more than 7 meters in length, intended for sport, leisure and recreation. However, we believe that the term *boat* is not sufficiently clear and to some extent it overlaps with the definitions of *smaller boat* and *yacht*. It is well known that in technical terminology, the terms *boat* and *smaller boat* are used as synonyms, while according to *the Safety of Maritime Navigation* it seems that *boat* is a subtype of *yacht*, which certainly was not what the legislator had in mind. The definition of a *boat* is unclear and unnecessary, consequently, we believe that it should be removed from the legislation. Furthermore, comparing *the Law on Safety of Maritime Navigation* to *the Ordinance on Smaller Boats*, which defines *smaller maritime boat* as a vessel designed to sail, with length of less than 12 meters, and the registration capacity of less than 15 gross tons, it is obvious that there are different definitions for the same term in different regulations.

It should also be noted that the Croatian and Montenegrin regulations differently define *yacht* as a vessel for sport and leisure. According to Croatian law a yacht is over 12 meters in length and it is registered for the stay and transport of not more than 12 persons, while according to the Montenegrin regulations *yacht* is at least 7 meters in length, without limitation in the number of persons.

After analyzing Croatian and Montenegrin regulations it can be concluded that in the definitions of vessels the only properly defined term is *ship* because this type of waterborne craft is subject to international regulations and standards. The definitions of vessels used in nautical tourism significantly differ both within the national legislation and between the two countries. This should not be the case in any way given that both countries have the same factors that influence the development of nautical tourism, and a similar profile of boaters-tourists staying on the vessels of nautical tourism. One gets the impression that it favours particular interest groups, and that there is no long-term vision of the legal regulation of such significant part of the maritime and tourist activities.

4. Maritime accidents and safety of navigation in the nautical ports aquatorium

4.1. Concept and types of maritime accidents

Since its beginnings, sailing has been accompanied by various risks that have endangered the safety of persons and property. Technical and technological advances in the construction and operation of vessels have reduced, but not eliminated the risk. This has also been contributed by an increasing number of different ships and craft engaged in international and national voyages. A maritime accident or incident is an event or set of events of the same origin that causes loss or damage to the ship, yacht, boat, cargo, other property at sea, which also causes human suffering (death or bodily injury of crew, passengers or third parties). The event that causes the maritime accident should be of exceptional nature - regular losses or expenses that accompany transportation and maritime activities are not maritime accidents. Maritime accidents can be caused by hazards of the sea (*force majeure* or unexpected occurrence) and actions of people who may be members of the ship's crew, or a third party. (Pavić, 2006)

In Croatia and Montenegro, national centres and sub-centres for coordination of search and rescue operations at sea provide assistance in the event of maritime accidents. Providing assistance in the event of maritime accident depends on the type and nature of the accident itself and the characteristics of the vessel, and the circumstances in which a harmful event occurred. Therefore, in continuation of this paper the basic features of maritime accidents shall be presented, emphasising those that are common to the vessels in nautical tourism.

The collision of vessels (yachts, boats) is material impact of two or more vessels, which results in damage to at least one vessel, property or the people on board. The collision of vessels (yachts, boats) usually occurs in narrow navigable waters (straits), or where there is heavy traffic (during entry or departure). Due to their often different sizes and speed, the nautical tourism vessels frequently suffer injuries or death of a person in the event of collision. (Luković et al., 2015)
The impact is a material collision of vessels with fixed sea or land structures; the term *impact* means that there is a powerful contact of a vessel with a structure that is not considered a craft. Most frequently, vessels suffer damage during the impact.
Grounding is a marine accident when the boat with its entire keel or just a part of it touches the bottom. Grounding usually occurs due to the error of the person that is navigating a vessel, or in the event of propulsion system failures due to the influence of wind and waves. The consequence may be severe damage to the hull due to its exposure to multiple impacts at the bottom.
The penetration of water (flooding) is any unintentional ingress of water in quantities threatening the seaworthiness of the vessel. The penetration usually occurs due to external forces (waves, mechanical impact force) or due to a malfunction of equipment parts.
Sinking of the vessel is an accident in which there is a permanent or temporary loss of seaworthiness and the loss of floating ability by its being fully or partially submerged in the sea.
The fire is uncontrolled burning mostly caused by maltreatment of vessel's equipment. The main characteristic of fire is its rapid spreading which leaves very little time for its prevention. Breaking out of a large fire regularly results in complete destruction of the vessel, and its sinking if it is far from the shore or in shallow waters. (Luković et al., 2015)
Person overboard is usually a result of negligence or falling from the ship. In case of bad weather, the person in water is at great risk, especially in case of low temperatures of the sea when the survival time is significantly reduced. (Luković et al., 2015)
Pollution of the marine environment can be caused by any vessel including the vessels of nautical tourism. Certainly there is a greater danger of ships, especially tankers, due to the type and quantity of the cargo transported. However, smaller vessels also pose a threat to the marine environment primarily by fuel leakage.
It should be noted that many accidents occur due to the very low level of expertise of persons who navigate the vessels of nautical tourism.

4.2. Safety in ports and convenience of nautical tourism ports

Sailing of the vessels of nautical tourism takes place for the most part near the indented coast, with numerous islands, islets, reefs, bays, creeks and sea straits. On the one hand, sailing in such areas is very exciting and provides direct contact with the beauty of nature, and on the other hand, there are many safe havens in case of adverse weather conditions.
From the standpoint of weather conditions affecting the safety of navigation, the sailing in the Adriatic Sea on the vessels of nautical tourism can be divided into two distinct areas: sailing in the open seas and in the coastal navigation area, relatively close to the ports of nautical tourism. These two areas are different in terms of effects of weather conditions on navigation and safety procedures in case of threats to the safety of navigation.
Depending on the size of the vessel, winds, waves and other weather factors have different effects on navigation, or altering the course and speed of the vessel. At the same time, the Adriatic sea is relatively safe for nautical vessels in the summer months, while it is quite the opposite in winter when it can get very unpleasant, especially for smaller vessels. The consequence of the above are two fundamentally different traffic periods: the summer months, during which a large number of vessels sail between different destination ports, and the winter period, during which the traffic of small boats is almost negligible and therefore, adverse weather conditions have a relatively small impact on the overall safety of navigation. (Luković et al., 2015)
From the standpoint of safety of navigation, nautical tourism ports provide a sufficient level of safety of vessels at berth, both during the summer when there are frequent arrivals and departures, as well as during the winter, at a time when most of the vessels have no permanent crew engaged.
The marina offers the highest level of security for vessels at berth. It should be noted that regarding the safety, the marinas built in the area that is not naturally protected from the effects of the sea may have parts in which there may be a higher uncertainty of mooring, under particular circumstances. This refers primarily to the marinas where the impact of waves has been reduced after the construction of breakwaters and where in case of full occupancy of the marina and in the event of a major storm, boats moored near the entrance may be exposed to intensive motions in the waves producing the relevant consequences. (Luković et al., 2015)
Mooring (berth) provides a different level of security to the vessels at berth. If it is placed deep in the protected bays or within the protected part of the public or other ports, the security guaranteed to the vessels is very high, especially if vessels of appropriate size are moored, and if adequate mooring equipment is used. In case of such mooring, it is possible to have a safe stay throughout the year including the winter storage of a vessel at its berth. Of course, there are opposite examples of mooring that are fully exposed to the bad weather conditions. In such cases, the mooring is possible only during the summer period.
Anchorage generally provides a satisfactory level of safety during the summer period. During the rest of the year, when the probability of adverse weather conditions is significantly higher, the safety of boats at anchor is often questionable.

In this respect the use of anchors, as a rule, is limited to the summer months.
Traffic in the areas near the ports of nautical tourism is affected by the characteristics of each port. However, the maritime traffic in the vicinity of the ports of nautical tourism and other parts of internal waters marks the annual turnover which is most pronounced during the summer period, weekly traffic which is most intense at the end of the week (when there are crew changes on the rented boats), and daily traffic which is significantly increased during the morning hours when the boats leave the port, or in the evening when a significant number of vessels return to spend the night in the port. (Luković et al., 2015)

4.3. Maritime accidents with regard to the type of nautical tourism vessels

Properties of certain vessels are crucial to the safety of navigation and protection of the marine environment. In nautical tourism there are numerous vessels of different characteristics and purpose, thus, the threats they are exposed to are very diverse.
From the standpoint of the threats boats and yachts are exposed to, it is possible to use the classification of these vessels by size, or the major propulsion they use, as well as by the speed they can develop. The propulsion of vessels can directly affect the shape of the hull, and consequently the conduct of these vessels in navigation. As a result, there is a distinction between the motor boats, yachts and sailboats. The speed that the boat develops when moving through the water is often crucial for the safety of navigation. In this regard we should distinguish boats and fast boats.
Regular boat speed is low, rarely over 7-8 knots. The boats that are smaller in length are usually owned by the local population, and are used for short stays at sea, at short distances from the coast, and in good weather conditions. They are moored in marinas, while some of them are anchored in naturally protected bays. It should be noted that the way of mooring and arrangement of boats in (sports) ports usually do not fully meet the standards of safety for berthing and stay of the vessel as a result of insufficient number of available berths, especially in the summer months. These boats are subject to accidents (collision, crash, sinking, etc.) at the place of berth, when manoeuvring in harbours or when sailing. Usually, the accidents that happen during the manoeuvring do not lead to the loss of the vessel. There are often incidents of boats hitting shore or other vessels at berth and the mooring ropes getting entangled in the ship's screw, usually due to manoeuvring errors. Accidents happen due to insufficient space for berthing in ports, particularly with regard to the width of the fairway and the space needed for manoeuvring, or because of too many boats in the harbour. The most common navigation accidents occur due to the failure of propulsion engine, stranding as a result of bad weather and a collision. Collisions may occur at low speeds (which rarely happens in practice), and they usually do not cause greater damage to the boat. In a collision of boats, of which at least one is moving at a higher speed, more serious damage may be caused, personal injuries or even a loss of life. (Luković et al., 2015)
Fast boats (speedboats) may be constructed of reinforced fibreglass, and they are often made of rubber (inflatable boats). Their weight is small, which makes them liable to the influence of wind forces. Their draft is also small allowing an easy access to the undeveloped coasts. At the same time, because they usually do not have a keel, it is very difficult for them to maintain the course. Their usual speed is 12-35 knots. They are often used for one-day sailing trips in good weather conditions. Most of these boats do not have permanent berth in harbours or marinas, and their owners transport them by roads or in winter, leave them in dry marinas that take care of their storage. In the period of their intensive use they are moored at the places for rent, or improvised berths set up by boat owners, and most often are not sufficiently sheltered. Only a small number of these boats are engaged on a berth contract with marinas. Accidents of fast boats equally occur at the place of mooring when manoeuvring in harbours and in navigation. The accidents during the manoeuvring of these boats do not differ from the accidents which involve similar boats of lower speed. Because they often use petrol engines, there is an increased risk of fire on these boats. In navigation, accidents occur mainly due to negligence, but also because of speeding. Events of a collision or grounding at higher speed result in considerable material damage, increased risk of injury and death of crew members and passengers. The accidents of fast boats often take place in the area less than 300 meters away from the coast and primarily due to non-compliance with the rule of sailing at reduced speeds. In this way, they pose a great threat to swimmers.
Yachts of up to 15 meters in length are fast vessels, usually constructed of reinforced fibreglass, of small weight and subject to greater influence of wind forces. The ratio of their surface and submerged parts is relatively large. These boats have very powerful engines that at low rpm develop considerable speed from 15 to 35 knots. Due to these characteristics, the skipper needs sufficient space, and he is required to possess considerable skills in controlling the yacht. Manoeuvring can become particularly difficult if the wind increases the speed. These yachts are commonly used for longer cruising excursions. During the year, a significant number of these vessels use permanent berths in the marinas. As they often change the ports for overnight stay, they are considered as transit vessels in the ports where they berth. With regard to the safety of navigation, everything that has been said of the fast boats applies to yachts of up to 15 meters in length, only they require significantly greater space for manoeuvring and mooring. These vessels rarely have accidents at sea and it is primarily because of their size that they rarely approach the coast, their equipment is more sophisticated, and they have better resistance to the impact of adverse weather conditions. Fires and explosions in this group of vessels are much rarer because they mainly use diesel engines. During the mooring these yachts often hit the shore, collide with other vessels or get the mooring ropes entangled in the propeller due to insufficient knowledge and skills of the persons who run them and external conditions.
Yachts of 15 to 30 meters and over are called *large yachts*. Although, due to their purpose, technological features and sophisticated equipment they seem similar to the previously described group of yachts, they are, in fact, much more

similar to ships. They mostly have a propeller or, sometimes, jet propulsion. The speeds developed by these yachts range from about 15 to 35 knots. They are usually used for longer cruises, and given their size they can easily navigate in adverse weather conditions. These vessels are often anchored outside the ports, and passengers are transported to shore by launches. Because of their length (especially yachts over 25 meters) they can only berth in larger marinas i.e. the larger ports open to public transport. The number of accidents of large yachts is much smaller in relation to the accidents of all other types of nautical tourism vessels. This is due to considerably better equipment, much better maintenance, and for the most part, the fact that they are run by qualified and experienced crew, and not by their owners or users. The characteristics of the accidents that occur are not significantly different from the characteristics of smaller ship accidents.
Regarding the threats to the safety of navigation of *sailing boat*s, it is most convenient to distinguish the sailing boats of up to 15 meters in length, and those over 15 meters. Sailing of boats of up to 15 meters is very similar to the sailing of boats and motor yachts of the same length. A significant difference occurs primarily in the part referring to the manoeuvring characteristics during the navigation in unfavourable weather conditions.
Sailing boats are very stable vessels, with large draft and lower freeboard they can maintain their course very well. These vessels develop the speed of about 10 knots by their propulsion units. Above described sailing boats are subject to grounding and less often to collision accidents due to quite low speed of navigation. The largest number of incidents of these vessels is caused by incompetence or inexperience of their skippers.
Larger sailing boats (more than 15 meters in length), or sailboats are generally technologically highly sophisticated craft. They can reach a length of more than one hundred meters, most often them are used as racing boats for the most demanding competitors, or as tourist boats intended for the most demanding clientele. In both cases, they are constructed of very expensive materials and with the latest state-of-the-art technology. As the handling of these vessels requires a high level of expertise, skills and experience, the same as large yachts, they are also run by qualified and experienced crew and therefore they are rarely involved in accidents. It is not common for these vessels to sail near the coast. The number, characteristics and frequency of their accidents approximately correspond to the number of accidents in passenger ships in international voyages.

5. Conclusion

Applicable Croatian and Montenegrin legal regulations have roots in former Yugoslavia regulations and therefore there is a lot of similarity in the current legal framework of both countries. Because of this and due to the international character of maritime affairs and tourism, most maritime law institutes governing nautical tourism are very similar. However, there are certain differences that have arisen due to the adjustment of particular institutes with national interests. This means the regulation of the legal status of vessels and nautical tourism ports, but not the provisions on maritime safety.
Although the vessels in nautical tourism are not subject to the provisions of international conventions, and are subject only to national legislation, both countries seek to meet high standards of navigation safety of yachts and boats, that being a prerequisite for the sustainable development of nautical tourism.
By analyzing the legal provisions applicable to the facilities of nautical tourism one can observe a large number of different laws and regulations that are not always mutually consistent neither in the legislation of individual countries nor in comparative law.
Inconsistency in definitions and types of nautical tourism facilities is also enhanced by the fact that the regulations in the domain of nautical tourism in Croatia and Montenegro are adopted within the framework of two different ministries – Maritime Affairs and Tourism. For the Ministry of Maritime Affairs the most important is the safety aspect of vessels navigating in the internal waters and territorial sea, while the Ministry of Tourism cares more for the tourist offer in nautical tourism as demonstrated by the categorization of specific regulations.
The analysis of the existing provisions shows that there are too many regulations that govern the activities of nautical tourism, hence the inconsistency, excessive regulation and legal gaps in the existing legislation. It all has certainly been affected by different political and economic interests that influence the adoption of various regulations. An example of this is Croatia which has been waiting for years for the adoption of a new and better quality A*ct on Maritime Domain and Seaports*. Because of different interests and conflicting opinions a series of attempts to adopt a new legal text have failed. Quality regulation of maritime domain is one of the preconditions for the efficient development of nautical tourism ports.
From all of this we can conclude that a thorough review of existing legislation in Croatia and Montenegro is essential, thus, the proposal for the set up of working groups in each country made up of experts who are engaged in the specific activities of nautical tourism in order to comprehensively and clearly regulate this important economic activity.

A VERIFICATION OF A REMOTE MONITORING OF RESULTS OF BALLAST WATER MANAGEMENT SYSTEM

Goran Bakalar[1], Myriam Beatriz Baggini[2]
[1,2] Bonum Mare Consulting LLC, 148 Young Ave, Cocoa Beach, 32932, FL, USA

Abstract: Remote monitoring of BW (ballast water), after being treated by any BWTS (Ballast Water Treatment System) on board ships is the only autonomous detection system for this purpose suggested at this time. The experience from ships indicated operational problems with the treatment of ballast water on board the ships. Another problem, confirmed by scientists, is re-growth of microorganisms after the treatment. Automated monitoring of treated BW on ships is a solution. It was specified, described and mathematically proved and verified in this article. Sophisticated part of this system, flow cytometer, needs some specific conditions for the operation. Important pressure reduction is an obligation and was explained and suggested the procedure and possibility of implementation. Remotely operated from land, this system improves traffic environment**.** Result of this study is a verification that brings up more trust in this automated system that verifies contents of ships' ballast water before a ship enters a port.

Keywords: remote operations, monitoring devices, ballast water management, flow cytometer.

1. Introduction

After and during the cargo loading from commercial ships, water is taken to ensure ship's strength and stability. This water is called ballast water. Non-native marine species arrive in ports via ballast water which is being discharged while the cargo is loaded. The BWMC (*Ballast Water Management Convention*) 2004 protects the sea environment through regulations regarding ballast water treatment (Bakalar, 2011). Therefore, most of ships will have to treat ballast water once the Convention comes into force. Regulations and standards established in D-2 regulation (Globallast, 2016) of the Convention, by the IMO (*International Maritime Organization*), require treatment limits to be met independently and calls for vessels to carry out monitoring themselves (Albert et al., 2013). Many successful, type approved technologies have been suggested for ballast water treatment (EPA, 2011; Lloyd's, 2014), such as disinfection with chlorine (Simpson, 2011), injecting chemicals (La Carbona et al., 2010), adding biocides to ballast water for the neutralisation of harmful microorganisms, sterilisation with ozone (Perins et al., 2006), filtration with UV (ultraviolet) light (Suherland et al., 2003), electro-ionization (Aliotta et al., 2001), exposure to cavitation (Cvetković et al., 2015; Cvetković et al., 2016), and magnetic separation (Ren et al.,2016). Some of the suggested type approved systems are more effective in neutralizing microorganisms such as bacteria and zooplankton and other systems cannot treat them so well. No system can inactivate all microorganisms in ballast water. Some states require implementation of sampling of treated ballast water before they approve and sign the Convention. The solution verified by authors in this article is a monitoring system that could be implemented in the maritime industry. A shipping company would make an additional confirmation of high quality of their operations if they implement this automated remote autonomous system in their fleet.

2. Materials and methods

Certain systems for detection of ballast water were suggested by scientists (Bakalar and Baggini, 2016; Bakalar and Baggini, 2016a; Bakalar and Tomas, 2011). It can be indication monitoring or compliance monitoring within required treatment limits. Indication means that the detection result proves that a treatment was performed. Compliance monitoring results show the exact amount of certain microorganism in a sample of ballast water. Some of the indication monitoring technologies work with enzimes and total energy detected in a sample. Another technologies, like Pulse-Amplitude-Modulation (PAM) fluorometry, measure fluorometric character of a particle (Schreiber,2004). The amount of remaining energy or enzimes is a proof of whether a ballast was treated at all or not. Flow cytometer is a detection sensor device of compliance monitoring and needs an operator just to calibrate it using a computer after each completed detection (Bakalar, 2014). The time of DNA detection in laboratories has been shortened from days in the past down to three hours (Asai et al., 2003). Flow cytometer is capable to scan 10,000 different particles per second (Bakalar, 2013). It detects all different DNA of the smallest microorganisms. That is needed because the smallest microorganisms were not included in BWMC 2004 (van Der Star et al., 2011). Also, regrowth of treated microorganisms (Grob et al., 2016; Liebich et al., 2012; Macintyre et al., 2016) would be cotrolled in this way. It is important that this detection sensor is capable to be operated autonomously and remotely. All other detection methods and their devices need significant operational assistance by humans (Bakalar and Tomas, 2016).

2.1. Automated autonomous remote system of detection of ballast water contents

Flow cytometer has been suggested by certain scientists to monitor chemical pollution from the ships in coastal areas (Bakalar et al., 2011). In Fig. 1 is a drawing of a system that has been suggested for early discovery of unwanted ballast water contents, using fixed flow cytometer, filtration of scanned data and communication sub-system that automatically transfers data from the ship to a land office. This system includes sub-systems and remote operation from the shore side

[1] Corresponding author: Goran.Bakalar@xnet.hr

office, autonomous from ship's crew. Flow cytometer could be fixed onto the ballast water pipeline system at the location that is available for detection of all ballast water tanks on board ship.

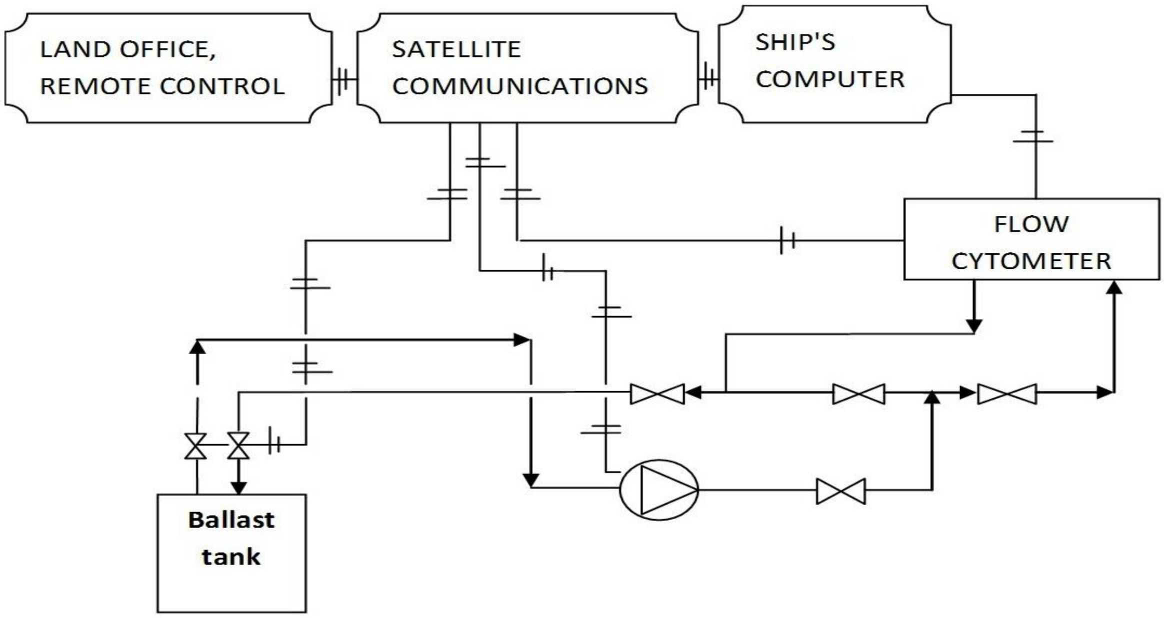

Fig. 1.
Remote detection system, using flow cytometer and satellite communication
Source: Modified from (Bakalar, 2013)

This system has been applied for a patent and it was presented in scientific and IMO conferences and published in scientific journals (Bakalar, 2015; Bakalar, 2016). The main purpose of this detection system is to timely, automatically and autonomously from ships' crew members, sample treated ballast water and send the information of ballast water status on a ship, to the land office. This system includes sub-systems and remote operation from the shore side office, autonomous from ship's crew. It is a remotely operated ship's ballast water detection system from land-based office. Remote communication of sensor data in ballast water treatment systems was researched (Kim et al., 2014) and trend analysis and diagnosis for BWTS remote monitoring of proper dosage in neutralization unit was analyzed (Choi et al., 2014). A fixed flow cytometer on the ship is remotely run that analyses treated ballast water with recirculation (Bakalar, 2012). The data of the flow cytometry scans are transmitted by an INMARSAT satellite communication system. Flow cytometer detects data after the dosing pump (inside the flow cytometer unit) takes on and off the samples. The software filters detected data after that. Software is programmed to filter and archive just needed information (related to D-2 regulation of BWMC 2004) (Bakalar, 2013). INMARSAT communication system transfers data on time, tunneling privacy with firewall network protection. The operator in land office performs remote control of ballast water. Remote operation is already in use in maritime industry for remote maintenance and supervision of some other processes on ships (Bakalar, 2012a). The control of contents of ballast water is remotely operated by the automatic detection of ship’s ballast water via satellite communication from land. It commences before the ship enters the port in which cargo will be loaded, in a manner agreed upon by the staff from the office located on land and the staff that is located on ship. Remote operation in this system includes opening valves of ballast water tanks, operation of ballast pump and operation of flow cytometer detection. Once the detection with negative results is completed, the operator in land office grants permit for the ship to enter port with confirmed clean ballast. If the result of detection was positive, the operator will not grant permit to ship to enter the port since flow cytometer detected discrepancy to D-2 regulation of the Convention. In Fig. 2. the pipelines flow cytometer unit are adjusted to reduce the pressure that has been driven from main ballast water pipeline into the flow cytometer detection unit.

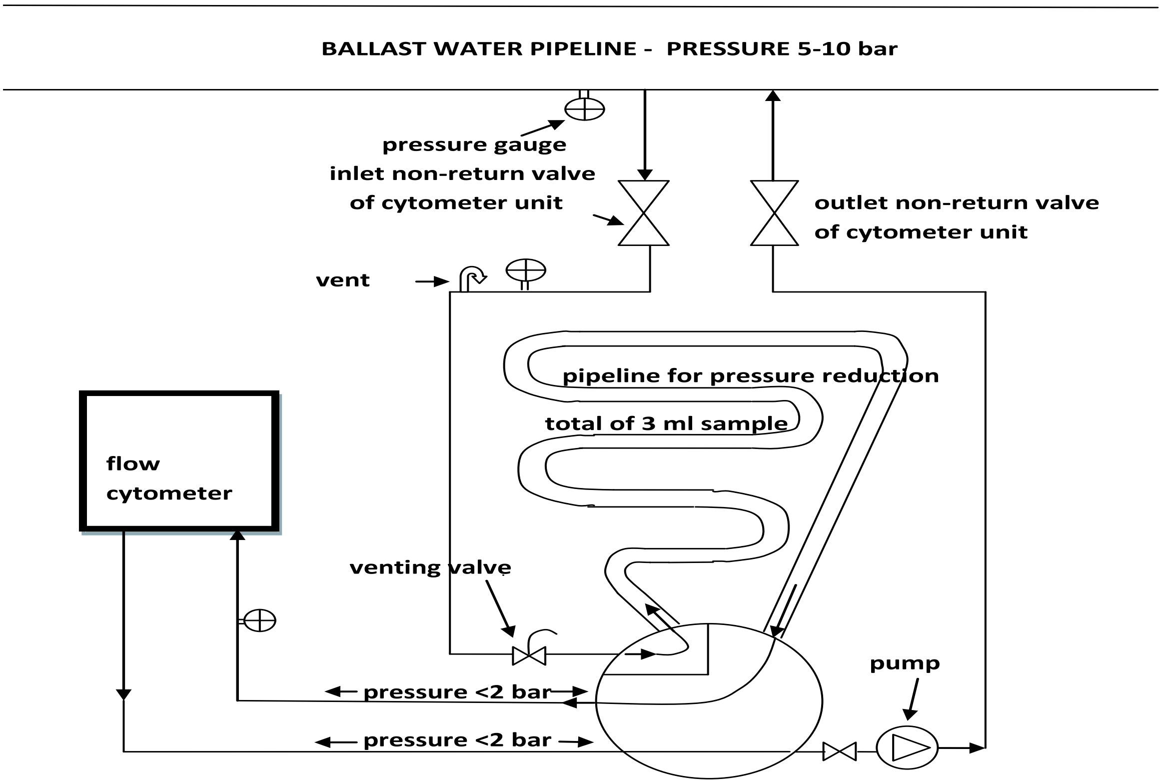

Fig. 2.
Flow cytometer unit

One of the most important conditions for flow cytometer, that needs to be verified, is the flow pressure of sampling water. The pressure cannot be higher than 2 bars, otherwise a flow cytometer would not be in proper operation (Bakalar, 2015). Verification of possibility of pressure reduction, in accordance with the drawing and suggestion in Fig. 2, is in following section.

3. A verification of the automated autonomous remote system of detection of ballast water contents

In following calculation is confirmed a pressure loss in flow cytometer unit. The pressure has to be lowered below 2 bars. That is a basic working condition for flow cytometer operation. As an example is taken a ship long L= 250 m, with width B= 50 m, hight of bulhead deck D= 25.

Inner diameter d_u is defined as follows:

$$d_u = 1.68\sqrt{L\ x\ (B+D)}\ + 25\ mm \tag{1}$$

and calculated diameter of ballast water pipeline is:

$$d_u = \sqrt{250x\ (50+25)}\ + 25\ mm = \sqrt{18750} + 25 \text{ mm} = 161.93 \text{ mm} \tag{2}$$

Ballast water flow through the pipeline is, in this case, stationary because the water fills whole inner diameter in the pipeline pressurised and driven by ballast pump maximum capacity of 2000 $\frac{m^3}{h}$ ili 0.555 $\frac{m^3}{s}$.

Pressure drop in a ballast water pipeline is in depend to inner resistance. Inner resistance is in depend of kind of flow, temperature and speed, and, the most important for this study, numerous kinds os narrowings in a pipelines system. The first pressure loss can be on T-connection, as shown on Fig. 2. That is the first connection of flow cytometer unit and ship's ballast water pipeline system. Next pressure reduction point is at inlet non-return valve of cytometer unit. Loss factor used for pressure loss in T-connection is ξ =0.11, added to pressure loss because of narrowing the space in the pipe of (calculated in 2nd equiation) 161.93 mm into 120 mm in relation

$\xi = \frac{120}{162}$. Pressure drop ξ of the narrowing at the valve is in relation to human operator and his decision or it was automaticaly ordered. Automatic valve can be narrowed of 30% of inner diameter in relation $\xi = \frac{80}{120}$ and pressure could be lowered down to required pressure by pump capacity that also can be regulated automaticaly or by operators' decision. Important factor is ballast water velocity:

$$\text{v = ballast water flow velocity } \frac{m^3}{s} \tag{3}$$

ξ of T-connection and narrowing of inner diameter of flow cytometer pipeline is:

$$\Delta p = \xi \text{ x } \frac{p\ x\ v^2}{2} = 0.81 \text{ x } \frac{5\ x\ (0.555\ \frac{m^3}{s})^2}{2} = 0.62375 \text{ bar} \tag{4}$$

ξ at the narrow of inner diameter caused by 30% reduced valve opening is:

$$\Delta p = \xi \text{ x } \frac{p\ x\ v^2}{2} = 0.66 \text{ x } \frac{4.37625\ x\ (0.555\ \frac{m^3}{s})^2}{2} = 0.674 \text{ bar za } \xi \tag{5}$$

The next step is pressure reduction by bending pipe of od *90°:* gained loss factor ξ = 1.2 and pressure reduction is:

$$\Delta p = \xi \text{ x } \frac{p\ x\ v^2}{2} = 1.2 \text{ x } \frac{3.70225\ x\ (0.555\ \frac{m^3}{s})^2}{2} = 0.68423 \text{ bar} \tag{6}$$

The last significant pressure loss is obtained by six times bended pipe, as agreed while the first author of this article was in visit in CytoBuoy institute, ξ =0,16:

$$\Delta p = \xi \text{ x } \frac{p\ x\ v^2}{2} = 6 \text{ x } 0.5 \text{ x } \frac{3.01802\ x\ (0.555\ \frac{m^3}{s})^2}{2} = 1.39444 \text{ bar} \tag{7}$$

Total pressure reduction till dosing pump in cytometer sampling unit is: ξ =3.37642

The measured pressure in main ship's ballast pipeline, at the beginning of this calculation, was 5 bar. The pressure was reduced down to 1.62358 bar and required pressure < 2 bar was verified. That pressure is good enough for proper flow cytometer function.

Malfunction index in this system is the relation between malfunctioning components and proper components:

$$\lambda = \frac{1}{P_c} \frac{d\,P_f}{\Delta t} \tag{8}$$

where P_c is the number of components which remained in proper functionality after a specified time, and P_f is the number of components which remained malfunctioning after the specified time of function.

Reliability of sophisticated part of the system is:

$$R\ (t) = P_c\ (t) = e^{-\lambda t} \tag{9}$$

which means that reliability in the function of time depends on probability of proper function and failures in specified time.

4. Discussion

Redundancy is the characteristic of computing system quality that ensures failure avoidance when a part of the system fails. This is most commonly ensured with additional spare software, by reliability of the two systems working parallely with achieved redundancy and a known malfunction index for these types of devices in determined on board the ships conditions.

It has been assumed in previous researches that the computing part of the subsystem in the system with two parallel subsystems, one of which is redundant, will be regularly maintained by operator and by self-diagnosing automatic function errors removal (Bakalar, 2016; Bakalar and Tomas, 2016). In this way, the possibility of malfunction of some ballast water treatment systems on board the ships is lowered. Malfunction index or failure for maintenance which is impossible to be diagnosed and automatically removed for this type of device of reliability for 1000 hours of work, Reliability of this type of sophisticated systems on ships was calculated in previous certain research and it was *R(t)* = 0.704688 (Bakalar, 2013). Total reliability of the whole computing subsystem as a part of some ballast water treatment systems on board the ships which consists of the two units of which one is software redundant is *R(u)* = 0.93097 (Bakalar, 2013). After the analysis of the reliability of the computing system, which is a subsystem of certain ballast water treatment systems on board the ships, the trust in this subsystem has been proven. The computing subsystem reliability with eventual use of redundant software is 0.931 or 93.1%. That reliability also has to be proven in the operations on board the ships. There were reported experienced operational problems with BWTS on ships (Bakalar, 2016a) and it was suggested action similar to suggestion in certain previous research (Bakalar, 2011a). System reliability of mechanical parts and system software reliability of 93.1% means that 6.9% of the operational time of any of the mentioned systems could be in failure or under repair. That is a high risk for the operation of BWTS and detection system verified in this study will be of great help in verification of results of performance of BWTS on ships.

5. Conclusion

Experience in operational ballast water management is hidden back data today. That is reasonable because of the profit in the maritime industry, marketing, reputation of shipping companies, ballast water treatment system inventors and institutes where the systems were tested and certified. Accidents data or malfunction and failure data of installed ballast water treatment systems are not available except to owners, classification companies or insurers. The only way for scientists to confirm proper performance of BWTS is to suggest control and supervision. Verification in this study helps to better understand a supervision system suggested in a previous research.

CROSS-TABULATION OF THE TOWS MATRIX: A NOVEL DIMENSION FOR ASSESSING THE COMPETITIVENESS OF MARITIME CLUSTERS

Peter J. Stavroulakis[1], Stratos Papadimitriou[2], Elena Riza[3]
[1,2] Department of Maritime Studies, University of Piraeus, Piraeus, Greece
[3] Medical School, University of Athens, Athens, Greece

Abstract: Industrial clusters have for decades been considered as a predominant sanctuary for competitiveness; a kind that is generated through symbiotic characteristics that are disposed to flourish through innovation dynamics. The research extract, that within industrial clusters, knowledge creation and innovation that lead to competitiveness are able to thrive, comes effortlessly. Within an industrial cluster the scarcity principle nearly vanishes and competitiveness may be attained through collective prosperity. Maritime clusters in particular can be considered as rudimentary in the formulation of regional strategic advantages, primarily due to the fact that the maritime sector holds a distinct and prevalent effect within any given economic cycle. Within the instruments formulated for industrial cluster research, the ones pertaining to strategic management do stand out, since effective strategy is a major factor of influence towards the health of an industrial cluster. It would seem that sustainable, adaptive and innovative strategy is what sets these clusters apart, majorly due to the fact that only within a strategic interpretation, can the opulence of a maritime cluster move into focus. Within this context, maritime clusters provide a rich framework for the generation and assessment of quantitative and qualitative methodologies and instruments; the present work aspires to contribute within this particular body of knowledge. The very useful TOWS matrix that can stand as the factor responsible for effective strategy formulation, is paired with cross-tabulation methodologies in order to relish the latter's arsenal of analytical potential. By introducing cross-tabulation within the TOWS matrix, an array of calculations can be relinquished that will in turn facilitate the process of strategy formulation. The application of this model may prove to be the instigator of sustainable competitiveness within a particular cluster, but furthermore, the instrument may find applicability within a plethora of strategic management cases.

Keywords: maritime cluster, competitiveness, strategic management, TOWS matrix, crosstab.

1. Introduction

Industrial clusters are the object of study and subsequent admiration, due to the fact that within them, a plethora of agreeable attributes, characteristics and dynamics, may not only reside, but thrive nonetheless. For instance, within industrial clusters, there seems to find solace a continuum that extracts instances of mutual opulence and collective prosperity. These traits, that seem to be shared within all efficient industrial clusters, suggest that within these industrial entities, a critical mass of innovation dynamics gives birth to sustainable competitive advantages for the firms within. These sustainable competitive advantages would not or could not reside outside the cluster. This goes to show that a firm that maybe would toil within any given setting, might thrive within an industrial cluster. This reincarnates industrial clusters to symbolizing beacons of collectiveness and mutuality. Thus the arrival to an industrial cluster's first paradoxical instance, that of the degeneration of the scarcity principle, leading to an evident scarcity paradox. This paradox would be the initial stance of analysis, for within it lies the key to understanding both the threads of industrial clusters and the caveat of the scarcity principle as well. As a firm pillar of economic theory, the scarcity principle stands to provide a given moral stand, as well as a latent underlying philosophy, that within a given geographical location, the quantity of resources is not infinite.

The aforementioned creed, that within a given location all natural resources should be treated as scarce, may pose as a discrete thread of a much needed requisition of respect towards the natural environment, by not treating proximity as an ever providing system; alas, within an industrial cluster it is just not applicable. This primal conflict of industrial cluster activity does pose itself as a paradoxical element, should an analysis consider the scarcity principle as a given. That the scarcity principle should be embedded in the foundation of any analytical query, is a proposition that does hold water, for it provides a quasi-level playing field for any proximate members. It also, for a kind, sets the tone of competitive dynamics within the proximate geographical location, for all stakeholders are aware of the resources that are to be exploited in order to obtain a competitive advantage. By extension, and taking under consideration modern strategic management thought, while a firm will promote its distinctive competence in order to obtain a sustainable competitive advantage, she will proceed to compete with other firms that are active within the given operations theatre. This understanding provides a very simple model for the interaction and subsequent evolution of proximate competition; since a resource is finite, the firms will compete for the given amount of the distinct resource. By extension, a question may surface as to the procedure that will be followed when a resource will render itself obsolete. Of course one could argue that the willing manifestation of the post-scarcity era will be the fixation and subsequent competition for another scarce resource, but through this prism a vicious cycle does emerge. As firms within a given proximity simply drain natural and other resources within a continuum, the question of sustainability surely becomes evident. Since firms strive for permanence and sustainable operations (that they themselves will reinforce the existence of the firm), the paradigm of resource scarcity does surrender its appeal and a novel understanding of sustainable activity may be afoot.

Within an industrial cluster setting, there seem to be a plethora of conflicting stakes that thrive altogether. The difference may be that any if not all resources pertain to potential resources and thus are utilized as before, but with the important distinction of life cycle continuity. This differentiation uncovers a basic latent ideal that can be found

[1] Corresponding author: pjstav@gmail.com

embedded in industrial clusters and many natural systems at large, that is, the culture of mutualism. Within industrial clusters, there are no destructive dynamics, but rather, a plethora of entities that coexist as one system, wherein the traditional understanding of scarcity theory is enriched with knowledge creation and innovation, that in turn facilitate the blossom of collective activity and unity that is engorged in a cluster. All the notions presented could not come to pass without that most basic characteristic of clusters, strategic management; the basis for all inherent activity within a cluster, is strategy. Strategic management is the catalyst that will facilitate all mutualistic dynamics and will formulate the sustainable competitive advantage of all entities within the cluster, to the point that it will seem that the competitive advantage belongs to the cluster itself. Within this domain, strategic management is the facilitator of competitiveness, through the formulation of quantitative and qualitative instruments that are tailored in order to assess and model the aforementioned competitiveness. This work pertains to such instruments, as it entails a novel approach as to the utilization of the TOWS matrix, an effective instrument of strategic management.

2. Strategic Management and Maritime Clusters

Industrial cluster dynamics come to alleviate the requirement of a more sustainable and constructive paradigm, through contesting the scarcity principle. The understanding of zero-sum eventualities that is adamant within a scarcity principle-woven world, is deconstructed and replaced with a dynamic and diverse culture of symbiosis, exact to natural occurrences. In nature, the paradigm of resource scarcity simply does not exist in the abstract, only in the absolute. That goes to say that in most, if not all natural systems, abundance is more evident than scarcity (McDonough & Braungart, 2002) and all activity is focused on obtaining a sustainable competitive advantage against predatorial eventualities, albeit environmental or systemic. But all this activity does not render the geographical proximity scarce, but conversely more versatile and rich. It is as though all entities through striving towards individualistic survival, contribute towards the evolution of the whole super-system; that there exists a latent systemic drive within these natural constructs, that enables collective prosperity rather than zero-sum games. A first observation should be that these occurrences may not hold an infinite life span; these systems portray the aforementioned extraordinary qualities for a time within their span of activity and not within an infinite continuum. Thus, nature will foster initiation or birth, growth, maturity and decay (again, exactly as within clusters) in a cyclical manifestation and for all levels of focal length, albeit a resource, an entity, or the sum of all systems that compose nature. A subsequent observation would be that there is evident correlation with Adam Smith's (1776) notorious 'invisible hand' and all its eventual corollaries, since (within industrial clusters) individual good is found to *somehow* guide the collective benefaction of the region.

The notion of the evident correlation of natural systems' dynamics with the absence, albeit paradox, of the scarcity principle, along with the eventuality of unhindered (and healthy) activity, that builds towards sustainable and collective mutualism, provides the cornerstone of industrial cluster theory. Thus, the two basic pillars that are mutually inclusive within industrial clusters, emerge as the circumvention of the scarcity principle, through a mechanism and process that is maybe not that transparent and a culture of self-maintenance, that again, through an oblique process, tends towards individual as well as collective tenacity, at least with respect to survival and evolution. A first attempt for understanding both these elements, could emerge from the apparent realization that the scarcity principle is self-evident. There is no way to create energy ex nihilo, as is dictated by the first law of thermodynamics and the law of the conservation of energy. As the first law of thermodynamics is the application of the law of conservation of energy for thermodynamic systems, so is the scarcity principle an application of the same law, but for systems of economies. As an isolated system for thermodynamics cannot produce energy but can only transform it, so do economies utilize finite resources and transform them into commodities, services and need-fulfilling items. Since the scarcity principle has such an airtight case, one must ponder the superficial divergence of industrial clusters from it and hazard a rational explanation for this discrepancy.

An initial explanation would situate itself as the eventuality that there are exceptions to the principle and that many natural systems that seem to break the scarcity principle by offering collective prosperity, are just instances of the scarcity principle's non-inclusion and thus, both the scarcity principle theory and many an instances where it is not applicable can be valid simultaneously. A deeper investigation as to the issue though, may reveal not only the absence of exception from the principle, but an absolute adherence towards its foundation. In order to explore this argument, one must backtrack to the law of conservation of energy. The law states that an isolated system cannot create and/or destroy energy, but merely transform it from one form into another, all the while keeping the sum of all energy a constant. If the sum of energy is to remain constant, thence the implicit conclusion with respect to resources is that they are neither created nor destroyed, rather transformed. Within this transformation, the initial form of the resource diminishes, leading to the point that this may be rendered exhausted. That a resource has been spent, in no way implies that it has been destroyed, or that another has been created from scratch, rather, that all resources may be undergoing a plethora of transformations within their life-cycle. Thence the question remains, why there resides a possibility that within a given geographical location and for a given time span, there seem to be competing entities all thriving simultaneously, within a given and finite number of natural resources, all with the scarcity principle valid. The answer is as credible as it is effortless. The entities do not compete upon a given amount of resources; they compete upon what may be considered a resource in the first place. Through this prism, the law of conservation of energy and the scarcity principle are not violated within any given scenario. Thus, the issue becomes one of visibility, or rather, of the ability to realize what a resource may entail.

Through this argument, one may ponder that the only way for a self-evident law of nature to remain un-breached and an apparent manifestation of collective prosperity (that is indisputable in so many natural systems) to be explained, is to reconsider what a resource entails in the first place. The narrow approach will discard mutualism as a discordance, an unyielding violation of a sound principle, whereas through a more inclusive approach, the at first paradoxical nature of collective sustainability will explain itself as a mere variation of the same principles. Thus, it will be a question of interpretation and subsequently, culture, if and how the scarcity principle is violated within an industrial cluster, for it is not only conflicted, but diligently adhered-to, nonetheless. At first viewing, the scarcity principle will pertain to the finite number of resources that have to be competitively and rigorously claimed by a different number of entities that are active in a particular field. At a subsequent level of detail, collective prosperity may be achieved within a given geographical location of finite resources by a growing number of firms, whence what may be conceived as such is regenerated. The only eventuality of the materialization of this version of the scarcity principle, is through a never ending plight that will reincarnate as the constant struggle of novel methods, ideas and solutions; what is widely considered to be the process of innovation. If the constituent of innovation is added to the threads of scarcity theory, thence the latter is not only not contested within so many natural systems that show such semblance to industrial clusters, but is adamantly reinforced, along with its backbone, the law of conservation of energy. All this theory requires to manifest any effectiveness and materiality, is the catalyst of strategy.

The basic approach of the latest years with respect to industry clusters, was the realization of the importance of strategic management within. From the rudiments of the theory, strategic management threads are apparent, but its explicit mention can only be traced in recent decades. Though Alfred Marshall (1890/1920), the first of neoclassical economists (Pinto, 1975), is mostly noted to have commenced the threads of modern industrial cluster theory, the father of location theory, von Thünen (1826), provided an excellent model for the effective concentration of economic activity. Within his work, there is mention of the appeal that Adam Smith's (1776) work had imposed. Smith's amazing construct of the 'invisible hand' that will guide a 'domestic industry' towards prosperity does formulate resonance to what today we would coin as industrial cluster dynamics. Thus, though Adam Smith is not formally attributed with an explicit contribution to the theory, there can be observed a correlation with his most infamous mention and cluster specifics. The entanglement of industrial clusters with instances that lean towards the paradoxical and the mysterious are merely one trait of clusters that facilitated many requirements for the emergence of strategic management. The latter is the vessel that pertains to the deconstruction of industrial clusters' obscurity, into analytically enabling traits. These obscurities are apparent in modern theory as well, many times in the form of paradoxes, such as the location paradox (Porter, 2000).

Though the cluster concept is not without caveats, albeit with respect to its applicability to specific industries (Steinle & Schiele, 2002), or with reference to the theory itself (Ortega-Colomer, 2016), recent research converges to the notion that maritime clusters provide inherent sources of regional competitive advantage (Antonopoulos, 2016). Even though the main industry from which the cluster has emerged may differentiate itself, regional competitiveness does seem to stem from an industrial cluster capacity (Doronina et al., 2016). The agreement always seems the same, that the fuel of clusters is innovation (Mazur et al., 2016). This process may very well be the output of an innovation system, or based on a specific constituent of innovation, such as collaborative innovation (Schaffers et al., 2016). Clusters do require severe scrutiny as to the process of innovation and provide a plethora of analytical potential thereof (Xie et al., 2016). Whichever the case, industrial clusters seem to be very important for strategic management (Dewally & Shao, 2015). This may be due to the fact that practice shows that one has a great influence over the other (Schiele, 2008), to the point that they may be intertwined with innovation dynamics as well (Rocha et al., 2010). Organizational adaptation may be added to the list (Niu, 2010), along with trust (Niu et al., 2012) and information networks (Casanueva et al., 2013), as drivers of industrial clusters' strategic management.

3. Cross-tabulation of the TOWS Matrix

The TOWS matrix (Fig. 1.) can be utilized as an effective instrument for mapping the different strategies available to an entity that is active within an industry cluster. Within a maritime cluster, it can pose as an extremely beneficial aspect of the strategy formulation process. Its potential strategic combinations are its major asset, for among the combinations of strategy, a firm may find a pertinent one and through this, benefit the cluster's super-system. Along with the SWOT analysis methodology, that is TOWS preceding step, the strategy formulation process for a maritime cluster can be streamlined and efficient. The methodology is utilized extensively within maritime clusters, albeit from a port perspective (Zauner, 2008), or within the focal length of a national cluster (Nordic Centre for Spatial Development, 2016). The analysis may be utilized within the exploration capacity of potential growth drivers (Danish Ministry of Economic and Business Affairs, 2006), or for analyzing national competitiveness (ECOTEC Research & Consulting, 2006). As SWOT analysis is utilized formally to present an analytical view for situation analysis, the TOWS matrix may be utilized as its progression, towards strategy formulation.

Through the utilization of the TOWS matrix, an analytical quantitative constituent may be absent and this may pose a hurdle for the efficient utilization of the instrument. This drawback may subside if cross-tabulation is introduced within the TOWS matrix items. The TOWS matrix results may be quantified and summed; for any item of the matrix, its quantitative elements may formulate a sum, such as, $a = \Sigma\ SO_n = SO_1 + SO_2 + \ldots + SO_n$, rendering a numerical result for each category. Thence, a basic crosstab (Fig. 2.) may be formulated.

Internal Origin / External Origin	Strengths	Weaknesses
Opportunities	SO Strategies	WO Strategies
Threats	ST Strategies	WT Strategies

Fig. 1.
The TOWS matrix
Source: Authors

The categorical variables of the crosstab can be the general categories of the TOWS matrix, or the preceding SWOT analysis items. Through this methodology, a novel instrument is relinquished, with the potential to portray different interpretations of the quantitative items. Through the numeric and statistical manipulation of items within the crosstab, statistical decision tests and risk factors may be calculated and interpreted, in order to portray any relevance and interdependence between the categorical variables. For example, basic measures of association can be extracted, based on the type of strategy formulation or case that is pursued.

Categorical variable 1 / Categorical variable 2	State 1i	State 1ii
State 2i	$a = \sum_{n=1}^{n_{SO}} SO_n$	$b = \sum_{n=1}^{n_{WO}} WO_n$
State 2ii	$c = \sum_{n=1}^{n_{ST}} ST_n$	$d = \sum_{n=1}^{n_{WT}} WT_n$

Fig. 2.
A generic crosstab
Source: Authors

Within crosstabs' plethora of methodological instruments, measures of association stand out as simple and practical items that enable the analysis with further informative potential. Especially for maritime clusters, measures of association can signify strategic essence, since they will provide readily available factors that guide any indication of association between the items of the crosstab. The attributable risk (AR = a – c = SO - ST) will show the relevance of the external environment within the formulation of strategies. The risk ratio [RR = a * (c + d) / c * (a + b) = SO * (ST + WT) / ST * (SO + WO)] will manifest the favorability of strengths with respect to opportunities, to that with reference to threats. Consequently, the odds ratio [OR = (a / c) / (b / d) = a * d / c * b = SO * WT / ST * WO] will present the impact of the external opportunities in creating favorable instances. In addition to measures of association, a plethora of further calculations may be administered, thus forming a calculatory arsenal that can be tailored with respect to given strategy formulation requirements.

4. Conclusion

A cost-effective methodology is relinquished that may hopefully prove to be effective in its practical utilization, within the domain of strategy formulation, in maritime clusters. Through the calculatory potential introduced by cross-tabulating the TOWS matrix, a plethora of statistical calculations may be administered, that will provide further guiding and decision making tools for the formulation of strategy within maritime clusters. The model is constrained by the limitation that in order for it to function, a quantitative understanding of the case must be portrayed. The latter may be susceptible to random as well as systematic error, not to mention error propagation. These hurdles may be overcome with diligent and materialistic processes, that will guide operations towards the effectiveness of strategy. Through this process, the competitiveness of maritime cluster members, as well as the competitiveness of the maritime cluster itself, may be assessed and pertinent strategic directions may be outlined.

[2] *University of Belgrade, Faculty of Transport and Traffic Engineering, Belgrade, Serbia*

Abstract: This paper investigates the identification of potential risks for the performance of maritime passenger transport activities in the ports. Passenger ports especially cruise ship ports in Adriatic Sea are facing with the constant growth in the passenger throughput over the last decade. The navigational safety traffic is characterized of the utmost importance. In this paper we try to quantify the possibilities for risk assessment occurrence of accidents of passenger ships including cruise and ferry ships especially in the narrow coastal areas such as Boka Kotorska Bay area in Montenegro. Here we concentrate on experts' judgments regarding the risk events' occurrence in the cruise port of call Kotor. According to their opinion we estimate the frequencies and consequences of possible risk events, such as collisions, groundings and so on. The results of this analysis enable the determination of the risk occurrence of accidents in the reported area. Finally, the proposal for the new scenario regarding the cruise ships servicing in Boka Kotorska Bay to increase navigation safety and security in passenger ports is specified.

Keywords: risk, passenger port, cruise ships, ferry ships.

1. Introduction

In this paper the nautical risk assessment in the case of Kotor cruise port (Boka Kotorska Bay, Montenegro) is investigated. We develop a model that is based on experts' judgment in relation to the frequency and consequence of risk events in defined navigational area. Also, we provide few numerical experiments as well as we propose some suggestions for avoidance of risk events when cruise ships would be serviced outside the Kotor Bay. For the realization of the specified problem, it is necessary to collect the appropriate data, identify the possibilities of risk event and propose a model. Therefore, the main goal of this research is directed to the identification of possible risks, the risk probability and the possibility of repeating the risk event after some period of time. The expert judgment provided in this analysis included consultations with pilots and ship's captains in order to separately give the estimation of the frequency and consequences of different risk events, namely: ship's collision, overtaking, grounding, navigation error, bad weather conditions and ship's breakdown.

The analysis of nautical risk assessment is investigated a lot in the previous period. Ships need to respect the rules of navigation especially in restricted and limited navigation area that represents narrow passage, so the general safety of all participants has to be provided. From the mathematical point of view, ship collision is described by geometric distribution (Debnath and Chin, 2010; Li et al., 2012; Montewka et al., 2010; Pedersen, 2002, 2010; Seong, 2012; Tan and Otay, 1999). Fowler and Sorgard (2000) evaluated that the accident is occurring as a result of the encounter between two ships and those are treated to be independent and different events. According to the analysis done by United States Coast Guard USCG (1999), different ships' encounters were discussed. Generally speaking, ship can change its speed and course in order to avoid the collision (Merrick et al., 2002). On the other side, some authors used automatic identification system in order to determine the level of congestion of maritime traffic in narrow passages. Their results were useful from the macroscopic maritime traffic modeling point of view. Main role of ships in modeling the avoidance of collisions is described and reported in Fujii and Tanaka (1971).

This paper is structured through five sections. In Section 2, the navigation area is described. Nautical risk assessment model with the appropriate parameters is provided in Section 3. Experimental analysis that includes the numerical examples with the proposal of new scenario of cruise and ferry ships' servicing in port is reported. Final section gives concluding remarks.

2. Navigation area

Kotor cruise port records the increased traffic volumes of cruise ships and is mostly oriented to nautical tourism. Likewise, Boka Kotorska Bay is situated in the southwest part of Montenegro. Nautical chart of the Bay is shown in Fig. 1. As it can be noticed, the Bay is divided into the four minor: Kotor, Risan, Tivat and Herceg-Novi. Upon the entrance, ships are passing through the Herceg-Novi Bay. The inner bays are the rest ones. In the Kotor Bay is located cruise port of call Kotor, recently recognized as a very popular place for tourists visit by ship. Therefore, the Kotor port was oriented to the cruise tourism. Approximately, it takes two hours that ship arrives to the port. Pilot station is located in Zelenika, 12.3 nautical miles from the Kotor port. The maximal ships' speed is 12 knots while entering to the pilot station, it reduces to 8 knots. At the beginning of the Kotor Bay, the speed of ships is only 4 knots. The conditions of safe ships moving inside the bay are provided due to the very well weather and nautical issues during the whole year. The maximal time of ships' maneuvering is around half an hour. Average depth in Kotor Bay is from 15 to 18 meters (Dragović et al., 2014, 2015; Kofjač et al., 2013; Škurić and Maraš, 2016).

[1] Corresponding author: Maja Škurić; email: majaskuric@gmail.com

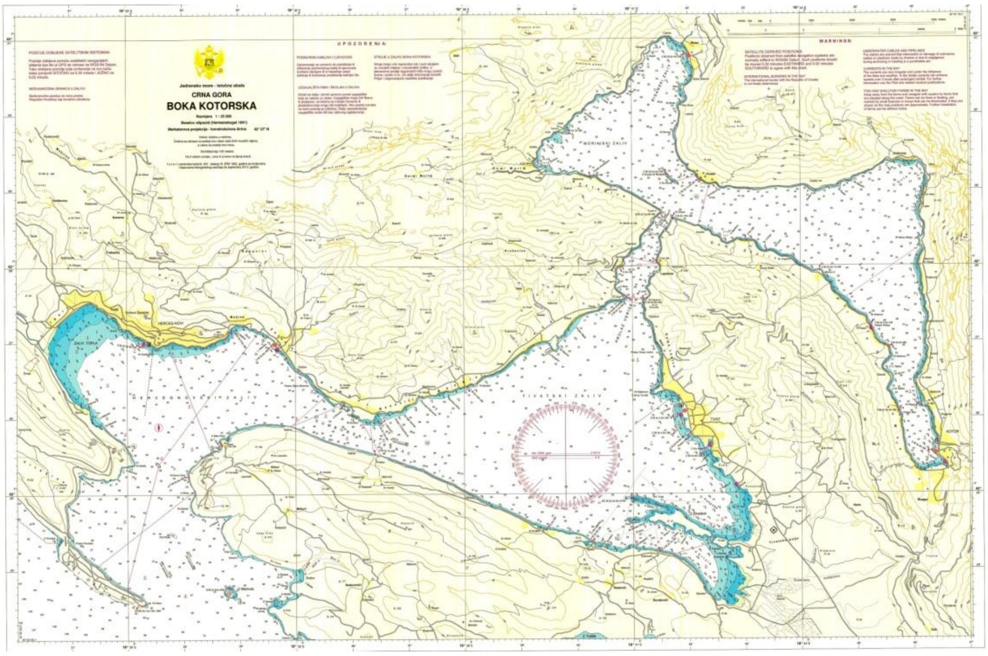

Fig. 1.
Nautical chart of Boka Kotorska Bay (PKAD, 2015)

Cruise ships in Kotor cruise port are servicing at the main berth, smaller river berth and two anchorages. At main berth, ships with length of 280 meters and draft of 8 meters can be serviced. Otherwise, ships are serviced at anchorages because there are no limitations in the ships' dimension. Ships with length of maximally 125 meters and draft of 4.5 meters are serviced at river berth. Anchorages are located 0.28 and 1.1 nautical miles from the port in Kotor Bay and frequently due to the operational policies, the anchorages are very used for ships' servicing. In addition, the trend of increased traffic is noticeable. In 2006 the total number of port calls of cruise ships was 155 while in 2015, 411 ships with around 440 thousand passengers visited Kotor cruise port. The average year increase in ships' traffic is 29%. The most frequent months are August, September and October. Sometimes, five or six ships per day are serviced in Kotor Bay area. Finally, the average number of passengers per ship call in 2006 was 235; in 2011 it was 600, while in 2015 it was 1075. In the case of servicing ships at anchorages, the port is using tendering service that implies lifeboats with capacity of 50 passengers for their embarking and disembarking.

3. Nautical risk assessment model

The quantification of nautical risk includes: identification of risk event, determining the probability of risk event, defining the loss rate produced by risk event and determining the risk rate. After the identification of risk event, it is necessary to designate its probability and quantify the loss that the risk event can produce. These are the basic indicators of the risk. The main methodologies for determining the level of risk are based on statistical data or expert judgments (Savić and Stanković, 2012). The first one is based on the probability theory while other on expert assessment. In this paper, we apply the second one. The probability of risk event P_e is in function of relative frequency of risk events is:

$$\mathrm{P_{re}} = R_e / n_{re} \tag{1}$$

Where; R_e: represent the number of risk events of the same type during a specified period of time, n_{re} is a number of possible realization of risk events in the same period. The values of risk events probability are from 0 to 1. Loss rate (number of passengers that are exposed to the risk event) in navigational area represents the mean of number of passengers that are participating in the same risk event (Savić and Stanković, 2012):

$$\mathrm{L} = \frac{1}{R_e} \sum_{j=1}^{R_e} L_j \tag{2}$$

Where; L_j: represents the rate loss caused by risk event j.
In this investigation, we apply the expert assessment on whose experience, knowledge and intuition is possible to meet the nautical risk in Boka Kotorska Bay. Beside the data of cruise ships' arrivals, here we assume that the local maritime transport of passengers from cruise ships is assigned to ferry passenger ships that are transferring tourists to the local ports. This methodology is used because of the insufficient information about the nautical risk probability, so it is

possible to model the realization of risk events. According to findings provided by Sulaiman et al. (2011) and Zaman et al. (2015), the classification of risk events is given in Table 1.

Table 1
Quantification of risk events' frequency

	Description	Probability of risk event
Negligible	Less often than once in 1000 years	$P_{re} \leq 0.001$
Small	Once between 100 and 1000 years	$0.001 \leq P_{re} \leq 0.01$
Occasionally	Once between 10 and 100 years	$0.01 \leq P_{re} \leq 0.1$
Probably	Once between 1 and 10 years	$0.1 \leq P_{re} \leq 1 \geq$
Frequently	Once or more during a year	$P_{re} \geq 1$

In this case, the experts are giving their opinions about the frequency of risk events as well as loss rate of their realization. In that way we provide the data of expected value of nautical risk, i.e. number of passengers from cruise and ferry ships that can be exposed to risk in the period of one year. But, firstly it is necessary to calculate the coefficient of concordance between the experts' opinions. In the case that coefficient of concordance is greater than 0.7, it is treated that the consensus of experts is provided. Otherwise, the process of evaluation should be succeeded (Savić, 2013). Based on their opinions, the ranking of experts' assessment is calculated. In this case, the smallest rank is given to the less frequency assessed by the experts and also this risk event is causing the smallest loss. In the case that more risk events have the same frequency or are causing the same loss, they have the same rank. Ranking that does not contain the same rank levels of events are named to be strict ranking, while the ranking that contains the same rank levels is called free ranking.

The coefficient of concordance for strict ranking is dependent on the total value of designed rankings (C) and total value of possible ranking (C_m) (Savić and Stanković, 2012; Цхадая я Подосенова, 2008):

$$W_d = C / C_m \tag{3}$$

Where;

$$C = \sum_{j=1}^{m} \left(\sum_{i=1}^{m} r_{ij} - \frac{m(n+1)}{2} \right)^2 \tag{4}$$

and

$$C_m = \frac{m^2 n}{12} \left(n^2 - 1 \right) \tag{5}$$

Where; n: a number of risk events, m: a number of experts in the analysis and r_{ij} represents the rank that the expert i assigned to the risk event j. In the case of free ranking, the coefficient of concordance is (Savić and Stanković, 2012; Цхадая я Подосенова, 2008):

$$W_f = C / C'_m \tag{6}$$

Where the total value of possible ranking is

$$C' = \frac{m^2 n}{12} \left(n^2 - 1 \right) - \frac{m}{12} \sum_{i=1}^{m} \left(\sum_{k=1}^{s_k} \left(s_k^3 - s_k \right) \right) \tag{7}$$

Where; s_k:is the number of the same rankings in group of ranks k of expert i, s_k represents the number of the groups of the same ranking provided by expert i.

After the evaluation of experts' consensus, the next is to determine the most probable values of frequencies and loss rate as well as the mean values of all experts. The expected risk value is calculated (Savić and Stanković, 2012; Цхадая я Подосенова, 2008):

$$R = \sum_{j=1}^{n} \overline{f_{rej}} \, \overline{L_j} \tag{8}$$

Where; $\overline{f_{re_j}}$: a mean frequency of risk event j, $\overline{L_j}$: mean of rate loss produced by risk event j.

4. Results

In this section we present some experimental analysis for calculating the expected values of risks in Kotor cruise port, mainly in Kotor Bay, based on the data of achieved traffic volumes of ships and passengers during a year. Considering the fact that cruise ships are serviced at main and river berth, as well as at anchorages, all located in Kotor Bay, the traffic density is very high during a year. Accordingly, the frequency of maritime transportation in a day is approximately 10 hours (taking into account that beside the cruise ship transport, here we suppose that the ferry transport of passengers to the local ports inside the Bay is active) and we start the experimental analysis that in a one-year-time-period, the total number of considered ships is 2000 (PKAD, 2015).

On the other side, for calculation expected values of risk, we interviewed three experts (denoted as e_1, e_2, e_3, respectively). The output data of their opinions regarding risk events' frequency and risk events' consequence are shown in Tables 2 and 3. They gave the independent opinions for six different categories of risks: ship's collision (r_{e1}), overtaking (r_{e2}), grounding (r_{e3}), navigation error (r_{e4}), bad weather conditions (r_{e5}) and ship's breakdown (r_{e6}).

Applying expressions (3-7) we calculate the expected value of risk using expression (8) that represents the number of passengers per year that is exposed to risk events. After the obtained result, we classify the frequency of risk events (f_{re}), as well as we calculated the period between the realization of two consecutive risk events in Boka Kotorska Bay.

Table 2

Experts' estimation of risk events' frequency (number of events per year)

	f_{re1}	f_{re2}	f_{re3}	f_{re4}	f_{re5}	f_{re5}
e_1	14	13	12	15	11	16
e_2	15	12	12	12	11	13
e_3	15	11	14	14	12	16

Table 3

Experts' estimation of risk events' consequence (number of events per year)

	L_{re1}	L_{re2}	L_{re3}	L_{re4}	L_{re5}	L_{re6}
e_1	50	10	260	100	5	90
e_2	73	13	270	50	5	120
e_3	50	15	395	50	5	75

Ranking and calculation of expected value of risk dependent on frequency and consequence of risk events is done in MATLAB-u 7.12.0, and contains the following steps:

1. First is to determine if there are the same frequencies or consequences in experts' opinions. In the case that there is no such a data, we use strict ranking, i.e. we assign the ranks from the lowest rank (1) to highest rank (6). Otherwise, in the case of the same frequencies, we calculate the mean of rank positions and they will have the same rank (we use the free ranking). The same is applied to the consequences,
2. The consensus of experts' opinions in frequency estimation is based on table data and coefficient of concordance. The same holds true for the consequence estimation,
3. We calculate the coefficient of concordance and the output shows the consensus of experts' opinions,
4. We calculate the mean of risk events' frequencies and consequences,
5. The expected value of risk expressed in number of passengers per year that is exposed to risk is obtained.

Finally, the coefficient of concordance regarding risk events' frequency of the considered example is 0.8133 which indicates the consensus of experts' opinions. In the case of risk events' consequence, the coefficient of concordance is 0.9359. The expected value of risk is 7297 passengers per year. If we assume that the total number of passengers that visited Boka Kotorska Bay is 450 thousand, the probability of realization of risk event is 0.0162, which implies that 62 years would be a period between the occurrences of two risk events. From the data in Table 1, we can conclude that the risk events' frequency belongs to occasionally class.

Following the same methodology, in Table 4 we did an experimental analysis for three cases with the input of opinions of two and three experts and five and six risk events. In the case of five events, we exclude the one of ship's breakdown. The result for a period between the realization of two consecutive risk events (E_{re}) in Boka Kotorska Bay is also provided.

Table 4
Results of expected risk values (passengers per year)

	Frequency data per year					Results			
	m	***n***	***C***	**C_m (C'_m)**	**W_d (W_f)**	***R* (pass.)**	**P_{re}**	**Class**	**E_{re} (year)**
Case 1	3	5	60.50	82.50	0.73333	487	0.00108	Small	926
	Consequence data per year								
	3	5	72.00	90.00	0.8000				
	Frequency data per year					**Results**			
	m	***n***	***C***	**C_m (C'_m)**	**W_d (W_f)**	***R* (pass.)**	**P_{re}**	**Class**	**E_{re} (year)**
Case 2	2	6	49.52	68.00	0.7282	599	0.00133	Small	752
	Consequence data per year								
	2	6	58.50	69.00	0.8478				
	Frequency data per year					**Results**			
	m	***n***	***C***	**C_m (C'_m)**	**W_d (W_f)**	***R* (pass.)**	**P_{re}**	**Class**	**E_{re} (year)**
Case 3	2	5	32.00	38.00	0.8421	942	0.00209	Small	479
	Consequence data per year								
	2	5	30.50	39.00	0.7821				

On the basis of output results and in the real case circumstances where the cruise ships are serviced, while ferry ship transport is developed in Boka Kotorska Bay, it is very important to take into consideration that the traffic density would be higher than in the case of servicing cruise and ferry ships in other inner bays of Boka Kotorska. So, for example, ships' servicing in Tivat or Risan's Bay would reduce the traffic density and appearance of risk events. Consequently, it is general opinion that the congestion of maritime transportation only in Kotor Bay can lead to the implementation of risk events and possible frequency of risk events. Therefore, it is necessary to predict the traffic intensity of all ships in bay in order to avoid the risk situations and thus prevent the endangerment of human life in this narrow area.

4.1. Proposal for new scenario of nautical risk decrease

Following the assumptions of experts, the possible situation of reducing the risk probability in Boka Kotorska Bay relies in new scenario that would include the displacement of cruise and ferry ships servicing from the Kotor Bay into the others. In that case the traffic volume of ships would be transferred to Tivat or Risan Bay, accordingly. There are few arguments that justify this scenario because the most important reason is related to the narrow passage in Kotor Bay in the case of increased maritime transport. Also, based on experts' opinions, the possibility of servicing ships in other bays is characterized to be a logical move due to the burdensome nautical area near the Kotor cruise port. The same methodology that is described in Section 3 and applying this model of nautical assessment confirms that 284 years will be a period between the realization of two consecutive risk events in Boka Kotorska Bay.

5. Conclusion

This paper deals with the nautical risk assessment in Boka Kotorska Bay, located in Montenegro, recognized as one of the most important node of nautical tourism in this part of Adriatic. However, in 2015 Kotor cruise port records 411 port calls with 420 thousand passengers. Having in mind that cruise ships are servicing at main berth, river berth and two anchorages, it is very important to investigate the level of nautical risk in the narrow area such as Kotor Bay where the port is located. Here we provided the information of navigational area, also, proposed a methodology to calculate the nautical risk assessment based on experts judgments, and finally gave some numerical examples in the case of five and six different risk events.

However, the whole methodology is very useful and accordingly we classified the frequency of risk event and predicted the time between the two consecutive events. In addition, the results obtained from the analysis are directed to the number of passengers from cruise and ferry ships (that will be employed soon) that would be exposed to the risk. On the other hand, the investigations such as this can serve to improve the communication and navigation issues in order to minimize the risk events in the future. Safety conditions need to be satisfied especially in passenger ports such as Kotor. New scenario for minimizing risk events in Kotor Bay is proposed. Therefore, there is a lot of space for improvement of this methodology, so further studies can be directed to the aspect of communication and electronic equipment that can be employed in the Boka Kotorska Bay in order to decrease the possibility of risk event realization.

SESSION 6: MULTIMODAL TRANSPORTATION AND LOGISTICS RESEARCH

SELECTION OF THE INTERMODAL TRANSPORT CHAIN VARIANT USING AHP METHOD

Slobodan Zežević[1], Snežana Tadić[2], Mladen Krstić[3]
[1,2,3] University of Belgrade, Faculty of Transport and Traffic Engineering, Serbia

Abstract: In the increasingly competitive world market freight transport faces demands for overcoming large distances while improving reliability and sustainability. Most of this transport is carried by road which generates various negative effects. On the other hand, intermodal transport allows the combination of different modes of transport, using the advantages of each of them. One of the problems in this area of research is the definition of the adequate transport modes and technologies combination, as well as the transport routes. Accordingly, the aim of this paper is to select the most favorable variant for the realization of the intermodal transport chain. As the decision-making process includes numerous conflicting criteria this is a problem of multi-criteria decision-making (MCDM) and must be accordingly addressed by the appropriate methods. The analytical hierarchy process (AHP) method is used in this paper and the applicability of the method for solving the defined problem is demonstrated by solving the case study of selecting the appropriate variant for the realization of the part of the intermodal transport chain from the port of Hamburg to trimodal terminal in Belgrade.

Keywords: intermodal transport chain, multi-criteria decision-making, AHP method.

1. Introduction

Increasing specialization and internationalization of the world trade leads to the increasing distances between suppliers, manufacturers and end users and the increase in the volume of world transport operations (OECD, 2010, UNCTAD, 2013). In the European Union, about 1,700 tons-kilometers of goods is transported in 2014, with the share of road transport of about 75% (Eurostat, 2015). A high share of road transport can be explained by the relative dense transport network that provides door-to-door transport and the high flexibility of route planning (Kummer, 2006). But the growing volume of road transport contributes to increasing road congestions, delays and other negative impacts on the reliability of transport (European Commission, 2012). In addition, transport is one of the main causes of harmful gases emission, noise and other negative impacts on the environment (European Commission, 2014). Consequently, companies are looking for alternative transport options that will enable them to reduce negative impacts of road transport and improve economic and environmental performance of their distribution systems (e.g. Demir et al., 2015). As a result, more and more researches are analyzing the negative impact of transport along the supply chain, with the aim of determining the consequences and ways to reduce them. The research results lead to the creation of policies that promote more intensive use of other modes of transport (rail, waterway) as well as the more intensive application of intermodal transport, which makes it possible to exploit the advantages of each mode of transport but also to eliminate their negative sides.

In the literature one can find different definitions or intermodal transport but the most widely accepted definition is that intermodal transport is movement of goods, in one and the same loading unit or a vehicle, by successive modes of transport without handling of the goods themselves when changing modes (ECMT, 1993). Various problems regarding intermodal transport are analyzed in the literature, such as the complementarities of different transport modes, changes in the price policy in intermodal systems, management of the flows between different modes of transport and their potential environmental impact, etc. (Sawadogo & Anciaux, 2010).

One of the problems faced by planners is to select the optimal route of goods transportation from the starting point (e.g. place of manufacture or supplier warehouse) to the endpoint (e.g. distribution center or retail warehouse). This is exactly the problem analyzed in this paper but in such a way to optimize the cost, time and performance while reducing environmental and social impacts. The aim is to support decision-makers (e.g. logistics operators) when selecting an appropriate route in the intermodal network, taking into consideration not only the criteria of time and costs, but also environmental and social criteria, and thus enabling them to choose the route, among the set of possible variants, that achieves a compromise between the benefits and negative impacts. As the achievement of this compromise implies consideration of different, mutually conflicting criteria, the problem is defined as a multi-criteria decision-making problem, and accordingly requires the application of appropriate method for its solution.

The paper is organized as follows. The second chapter describes in more detail the problem analyzed in this paper, i.e. the selection of the best variant for the realization of the part of the intermodal transport chain, as well as the criteria used in the decision making process. The third chapter describes the decision making method, AHP method, which is used for solving the case study. The fourth chapter describes the case study and presents the obtained results. Fifth chapter gives the concluding remarks.

2. Intermodal transport chain variant selection

When talking about transport chains optimization, most talk about the problems of finding the shortest or most economical route between the initial and final terminal, reducing transport costs while performing the delivery within a

[3] Corresponding author: m.krstic@sf.bg.ac.rs

reasonable period of time, reducing the cost of routing for each delivery in relation to the total cost of transport and inventories, finding the optimal mix of transport alternatives to reduce overall logistics costs, comparing different forms of transport and technologies in relation to the internal and external costs, etc. (Sawadogo & Anciaux, 2010). A special class of problems are the problems of selecting the routes in intermodal transport networks (e.g. Qu & Chen, 2008) and this is exactly the problem discussed in this paper. The aim is to choose the best variant of intermodal transport chain realization for a set of criteria. The problem is defined as the transport of intermodal transport units - Twenty-Feet Equivalent Units (TEUs), i.e. ***q*** pallets of goods (where q_u is the number of pallets in one TEU), along the road ***r***, from the starting point ***O*** to the end point ***D***. Every route ***r*** is the possible variant ***V*** and can be composed of multiple sections ***i (i=1,...,n)***. Each section represents part of the route with the length ***d***, while ***μ*** represents the number of vehicles of a certain transport mode ***m*** used for the transportation of goods. The selection of variant is based on the following criteria: transportation costs (C1), transportation time (C2), particle emissions (C3), noise emissions (C4), energy consumption (C5), traffic congestion (C6), transshipment time (C7), transshipment damages (C8) and accidents (C9), which are described in more detail below.

C1: Transportation costs. Transportation costs include fixed costs, fleet personnel costs and variable costs that depend on the traveled distance (fuels, tolls, etc.), and can be expressed by the following equation:

$$C1 = \sum_{i=1}^{n} \left[\left(c1_{im} + t_i c2_{im} + d_i c3_{im} \right) \mu_{im} \right] \tag{1}$$

where $c1_{im}$ denotes fixed costs of using transport mode *m*, $c2_{im}$ costs of hiring fleet personnel for the transport mode *m*, $c3_{im}$ costs of the distance traveled by the transport mode *m*, t_i transportation time on the section *i*, d_i length of the section *i*, and μ_{im} number of transport means *m* used on the section *i*.

C2: Transportation time. The criterion includes driving time and does not include time losses that may arise due to the border and customs control, traffic congestion, the regulations on the duration and the period of transport, etc. The transportation time is obtained by using the following equation:

$$C2 = \sum_{i=1}^{n} d_i / v_{im} * \mu_{im} \tag{2}$$

where v_{im} denotes the velocity of vehicles of the transport mode *m* on route section *i*.

C3: Particle emissions. The emission of harmful particles into the air by means of transport can be calculated using the following equation:

$$C3 = \sum_{i=1}^{n} \sum_{e=1}^{g} u * d_i * \rho_{iem} \tag{3}$$

where ρ_{iem} denotes the quantity of emitted harmful particles *e (e=1,...,g)* on route section *i* by the transport mode *m*.

C4: Noise emissions. Noise emission can be displayed using the following equation:

$$C4 = \sum_{i=1}^{n} u * d_i * \beta_{im} \tag{4}$$

where β_{im} denotes average costs of the noise emission for the transport mode *m*.

C5: Energy consumption. Energy consumption can be obtained by using the following equation:

$$C5 = \sum_{i=1}^{n} u * d_i * \varepsilon_{im} \tag{5}$$

where ε_{im} denotes the energy consumption of the transport mode *m*.

C6: Traffic congestion. Traffic congestion can be obtained by using the following equation:

$$C6 = \sum_{i=1}^{n} u * d_i * \chi_{im} \tag{6}$$

where χ_{im} denotes average costs of the traffic congestion for the transport mode *m*.

C7: Transshipment time. The transshipment time includes all times necessary for loading and unloading pallets to/from the transport unit and the times of transshipment TEU in breaking points, and can be obtained using the following equation:

$$C7 = u * \Delta_u * (2 + 2b_r) + q * \Delta_q \tag{7}$$

where Δ_u denotes average time for transshipment of one TEU, Δ_q average time for transshipment of one pallet, b_r number of breaking points on the route *r*.

C8: Transshipment damages. The cost of damaging the goods during transshipment can be obtained using the following equation:

$$C8 = u * \delta_u * p_u * (2 + 2b_r) + q * \delta_q * p_q \tag{8}$$

where δ_u denotes the average costs of damaging the goods during the transshipment of one TEU, δ_u average costs of damaging the goods during the transshipment of one pallet, p_u the probability of damaging the goods during the transshipment of one TEU, and p_q the probability of damaging the goods during the transshipment of one pallet.

C9: Accidents. Costs incurred as a result of an accident can be obtained using the following equation:

$$C9 = \sum_{i=1}^{n} u * d_i * \alpha_{im} \tag{9}$$

where α_{im} denotes average costs arising from accidents during transportation by the transport mode m.
For the calculation of the variants values in relation to the criteria, it is necessary to define the values of the parameters that appear in the previously defined equations (Table 1).

Table 1
Values of the parameters for the calculation of the variant values in relation to criteria

Parameter	Units	Road	Rail	Waterway
Capacity	TEU	2	120	180
c1	€	100	200	200
c2	€/h	20	26.27	26.27

The ultimate goal is to find a compromise solution for all the above criteria, which is why there is a need for the use of multi-criteria decision-making methods. For this purpose, AHP method, described in more detail bellow, is used in this paper.

3. AHP method

The multi-criteria decision-making problem described in this paper can be solved by using AHP method. AHP method developed by Saaty (1980) deals with the determination of the relative importance of criteria in multi-criteria decision-making problems. AHP method is based on three principles: the structure of the model, a comparative analysis of the structural elements (criteria and alternatives), and synthesis of priorities. The first step in applying the method is the formation of the hierarchical structure of the problem being solved. AHP first decompose a complex multi-criteria decision-making problem into a hierarchically arranged elements (objectives, criteria, alternatives). In general, according to the defined problem an analysis is performed to determine the relative weights of criteria at each hierarchical level and value of alternatives against the criteria. This analysis includes pair-wise comparison of all criteria in each hierarchical level as well as the pair-wise comparison of all alternatives against the criteria. The pair-wise comparison is performed by applying the standardized nine-point scale (Saaty scale) (Table 2).

Table 2
Saaty scale for criteria evaluation

Numerical value	Linguistic assessment
1	Equal importance
3	Moderate importance
5	Strong importance
7	Very strong importance
9	Extreme importance
2,4,6 i 8	Intermediate values

Steps of applying the AHP method are described below.
Step 1: Define the problem structure. First, it is necessary to define the elements of the structure, i.e. the objective, alternatives (variants) and the criteria for their prioritization.
Step 2: Form a matrix for pair wise comparison of the elements:

$$A=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1o} \\ a_{21} & a_{22} & \cdots & a_{2o} \\ \vdots & \vdots & \ddots & \vdots \\ a_{o1} & a_{o2} & \cdots & a_{oo} \end{bmatrix}, a_{kk}=1, a_{lk}=1/a_{kl}, a_{kl}\neq 0 \tag{10}$$

elements of which are a_{kl} $(k,l=1,2,...,o)$ and denote the importance of element *k* in relation to element *l*.
Step 3: Obtain the element weights based on the eigenvector. First, it is necessary to set up a matrix equation:

$$AW=\lambda_{\max}W \tag{11}$$

where W is the element weights matrix, and λ_{max} is the eigenvalue of the matrix *A*. Equation (11) becomes equation:

$$(A-\lambda_{\max}I)W=0 \tag{12}$$

where *I* is the identity matrix (matrix whose elements on the main diagonal have a value of 1).
λ_{max} is obtained by solving the equation:

$$\det(A-\lambda_{\max}I)=0\ . \tag{13}$$

Based on the value λ_{max} and by transforming the matrix equation (12), the system of linear equations is obtained. By solving this system of equations, while respecting the condition $\sum_{k=1}^{o} w_k = 1$, the values of the element weights w_k are obtained.
Step 4: Determine the consistency of the evaluations. In order to control the results of the method it is necessary to calculate the Consistency Ratio (*CR*) for each matrix and the overall inconsistency of the hierarchical structure. *CR* is calculated as follows (Saaty, 1996):

$$CR=CI/RI, \tag{14}$$

where *CI* denotes the Consistency Index and can be calculated as:

$$CI=\frac{\lambda_{\max}-n}{n-1} \tag{15}$$

RI denotes the Random Index values of which, for the matrix of different sizes, can be seen in the paper of Saaty (1996). *CR* is used for checking the consistency of pair wise comparisons and must be less than 0.10. Only then it can be said that the comparisons are acceptable.

4. Case study

In Serbia, in 2015, more than half a million tons of goods are imported from the countries of the Far East (National Statistics Institute). From the Far East ports, these goods are delivered in containers to the European ports, from where they are transported to Serbia. Most of the goods are coming into Europe via the northern-European ports, among which the port of Hamburg has a significant role in the realization of these flows. Port of Hamburg had in 2015 a turnover of 8.8 million TEUs, out of which over 50% was achieved with the Far Eastern ports (Port of Hamburg - statistics). Due to all the above, the objective of this paper is to analyse the part of the intermodal transport chain from the port of Hamburg in Germany to trimodal terminal (road, rail, river) in Belgrade, Serbia. For the realization of this transport chain, several variants are defined by combining available modes and different technologies of transport.
The problem includes the transport of 1,500t of goods, i.e. 3,000 pallets with the dimensions of 1,000x1,200 mm, whereby each pallet holds 500 kg of goods. 20 feet containers are filled with palletized goods in such a way that 100 containers are needed for transporting the entire quantity of goods, wherein each container holds 30 pallets. For the realization of the transport chain five variants (V) described below are defined (Figure 1).

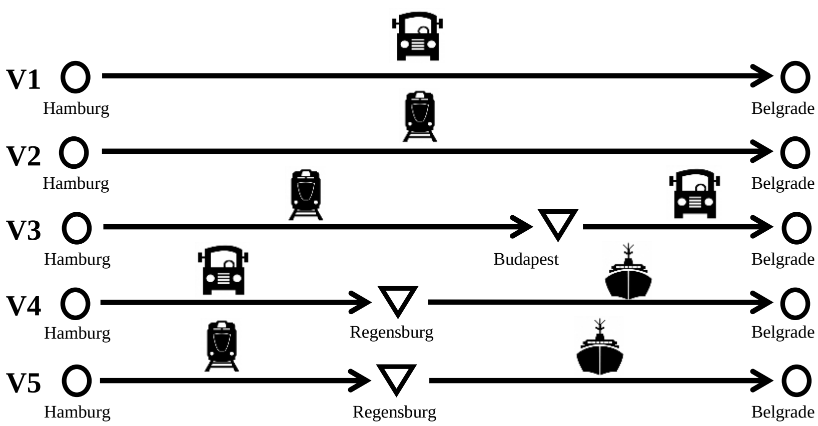

Fig. 1.
Transport chain variants

V1 – Direct road transport. The first variant includes a direct road transport of goods from the port of Hamburg to trimodal terminal in Belgrade. Goods packed in containers arrive to the port of Hamburg by ocean carriers. In the port of Hamburg containers are loaded onto the road transport vehicles that transport them to the Belgrade terminal. As the transportation from Hamburg to Belgrade is performed only by road transport, there are no breaking points. The goods are being unloaded from the containers in the terminal in Belgrade.
V2 – Direct railway transport. Second variant implies a direct rail transport from the port of Hamburg to the terminal in Belgrade. Similar to the variant 1, in the port of Hamburg containers are loaded onto railroad cars that transport them to Belgrade, without breaking points. Transport from Hamburg to Prague is performed through the part of the European rail freight corridor "North Sea-Baltic", then through the part of the corridor "Orient" from Prague to Budapest, and at last through B branch of the pan-European Corridor 10 from Budapest to Belgrade. The goods are being unloaded from the containers in the terminal in Belgrade.
V3 – Rail-road transport. The third option involves the transport of containers by using rail and road transport. Containers are loaded onto the railroad cars in Hamburg, and then transported from Hamburg to Budapest through the rail freight corridors "North Sea-Baltic" and "Orient". In Budapest, the change from rail to road transport mode occurs, since the section of the route from Budapest to Belgrade does not belong to the network of European rail freight corridors, therefore the costs are higher and speed considerably lower. The goods are being unloaded from the containers in the terminal in Belgrade.
V4 – Road-inland waterway transport. The fourth variant involves the transport of containers, loaded in Hamburg on the road freight vehicles, from the port of Hamburg to the port of Regensburg on the Danube. In the port of Regensburg, containers are being transshipped from road transport vehicles to the river barges, and then transported by Danube to the terminal in Belgrade. Containers are being transshipped and the goods unloaded from the containers in the terminal in Belgrade.
V5 – Rail-inland waterway transport. In the fifth variant, the containers are being loaded onto the railroad cars in the port of Hamburg and transported to the port of Regensburg. Between the ports of Hamburg and Regensburg there are regular lines of block trains, which transport 5 times a week. In the port of Regensburg, the containers are being transshipped from the railroad wagons onto the river barges and then transported by the Danube to the terminal in Belgrade, where the containers are being transshipped from the barges and the goods unloaded from the containers.
The distances traveled in each variant, by each mode of transport, as well as the total distances traveled are shown in Table 3.

Table 3
Distances traveled in each variant of the transport chain (km)

	Road	**Railway**	**Inland waterway**	**Total**
V1	1,534	/	/	1,534
V2	/	1,505	/	1,505
V3	380	1,185	/	1,565
V4	704	/	1,210	1,914
V5	/	750	1,210	1,960

First, it is necessary to define the hierarchical structure of the problem, which is shown in Figure 2.

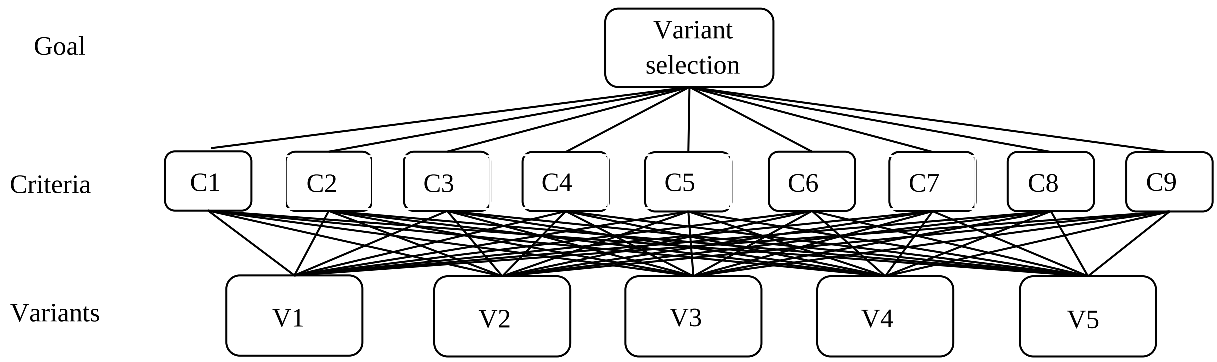

Fig. 2.
Hierarchical structure of the problem

Afterwards it is necessary to determine the criteria weights. By comparing the pairs of criteria in relation to the objective, ussing the Saaty scale given in Table 2, the resulting matrix A shown in Table 4 is obtained.

Table 4
Criteria pair wise comparison matrix

	C1	C2	C3	C4	C5	C6	C7	C8	C9
C1	1.00	3.00	2.00	6.00	2.00	5.00	7.00	4.00	5.00
C2	0.33	1.00	0.50	4.00	0.50	3.00	5.00	2.00	3.00
C3	0.50	2.00	1.00	5.00	1.00	4.00	6.00	3.00	4.00
C4	0.17	0.25	0.20	1.00	0.20	0.50	2.00	0.33	0.50
C5	0.50	2.00	1.00	5.00	1.00	4.00	6.00	3.00	4.00
C6	0.20	0.33	0.25	2.00	0.25	1.00	3.00	0.50	1.00
C7	0.14	0.20	0.16	0.50	0.16	0.33	1.00	0.25	0.33
C8	0.25	0.50	0.33	3.00	0.33	2.00	4.00	1.00	2.00
C9	0.20	0.33	0.25	2.00	0.25	1.00	3.00	0.50	1.00

By solving the equation (13) for the given matrix the largest eigenvalue $\lambda_{max} = 9.205$ is obtained. Matrix equation (12) is then transformed into the system of linear equations, and by solving it the values of criteria weights *W=(0.277, 0.120, 0.184, 0.033, 0.184, 0.050, 0.023, 0.079, 0.050)* are obtained. By applying the equations (14) and (15) the value of CR=0.018 is obtained. As the values of CR is less than 0.10 it can be said that the evaluation is consistent.
After the criteria weights are obtained, the calculation of values of the variants in relation to criteria is performed by using the equations (1) – (9) and the parameters shown in Table 1. On the basis of these values, a comparison of all pairs of variants in relation to each criterion is performed by using the Saaty scale given in Table 2. Matrices obtained in this way are shown in Table 5.

By applying the equation (13) and by solving the system of equations obtained by transforming the equation (12) for each matrix in Table 5, the preference values of variants in relation to each criteria are obtained. These values, as well as the final weighted preference values of variants are shown in Table 6.

Table 6
Preference values of variants and final ranking

Criterion	C1	C2	C3	C4	C5	C6	C7	C8	C9	Preference value	Rank
Weight	0.277	0.120	0.184	0.033	0.184	0.050	0.023	0.079	0.050		
V1	0.049	0.062	0.036	0.231	0.053	0.036	0.286	0.313	0.056	0.0809	5
V2	0.420	0.419	0.325	0.037	0.322	0.295	0.286	0.313	0.247	0.3453	1
V3	0.164	0.160	0.192	0.055	0.188	0.135	0.143	0.176	0.141	0.1674	3
V4	0.102	0.097	0.121	0.562	0.115	0.089	0.143	0.098	0.141	0.1244	4
V5	0.265	0.263	0.325	0.114	0.322	0.445	0.143	0.098	0.415	0.2818	2

Based on the results, it can be seen that the variant 2, which involves the railway transport of containers from the port of Hamburg to the trimodal terminal in Belgrade, proved to be the most favorable one in terms of the considered criteria. On the other hand, the least favorable variant is the variant of road transport of containers. In addition, all variants which included road transport were worse than the variants without the road transport, which confirms the thesis that (in terms of the considered criteria) it is more favorable to shift the goods flows from road to other modes of transport (railway and inland waterway) as much as possible.

5. Conclusion

In most developed countries, most of the freight transport is performed by road transport, while railway and inland waterway transport are either underutilized or very disorganized in terms of functioning and coordination with other modes of transport. Road freight transport recorded a steady increase in the past few decades. This has led to serious overload of road networks without significant improvement of existing infrastructure resulting in many negative effects such as higher external costs, traffic congestion, increased energy consumption, negative environmental impacts, etc.
These negative effects can be significantly mitigated through the efficient organization of intermodal transport system. Such systems can dramatically improve the utilization of transport resources and services, which leads to better planning and deliveries with lower logistics costs and higher levels of efficiency, and one of the ways to achieve these results is adequate planning of transport chains. The subject of this paper was the planning of one part of the transport chain, from Hamburg to Belgrade, i.e. the selection of the best variant of realization of the chain in relation to the defined criteria. As the problem involves consideration of a large number of criteria, it was necessary to apply a multi-criteria decision-making method for its solution, and accordingly in this paper the AHP method is used for this purpose. The results clearly show that minimization of the use of road transport, with greater use of other modes of transport (such as railway and inland waterway) lead to better results in terms of the considered criteria, whereby in the case considered in this paper, the variant that included the railway transport of containers is obtained as the best one.

TERMINAL FOR CUSTOMER-FRIENDLY LOGISTICS SERVICES

Petra Matzenberger[1], Volker Hartl-Benz[2], Bernhard Rüger[3]
[1,2,3] *Vienna University of Technology, Institute of Transportation, Research Centre of Railway Engineering, Traffic Economics and Ropeways, Austria*

Abstract: The transport of small freight (general cargo, baggage and packages) is definitely increasing at the moment. This is supported by online commerce. Current delivery services are inflexible concerning customers' needs and demands. For example the person's physical presence is necessary at the delivery address to accept it or the person has to pick up the package in a shop. Moreover, delivery services were often uneconomic because they needed several delivery attempts. This was the reason for the exploratory project smartBOX. The intention of smartBOX (founded by the Austrian Ministry for Transport, Innovation and Technology and the Austrian Research Promotion Agency) was to combine increasing mobility requirements and tightening resources by creating an intelligent and holistic approach. Visionary mechanisms of autonomous traffic optimisation together with cross-sectoral transport and service models as well as the development of terminals and intelligent containers and transport, information and communication technologies could help managing the challenges of small freight mobility in urban areas, increasing quality of life and saving the environment. In order to minimise the development risks it was first necessary to survey and define all requirements. Therefore, extensive customer surveys were conducted.

Keywords: logistics services, terminal, box, freight mobility, package, luggage.

1. Introduction

The transport of small freight (general cargo, baggage and packages) is definitely increasing at the moment. In fact, this market has been the fastest-growing transportation segment in the United States over the past two decades. For the parcel delivery industry it is typical that they are multimodal. They use small trucks, cars or messengers for pickup and delivery and another mode of transport such as a truck, the railway or planes for the line-haul. (William, 2009)
Actual trends of the small freight logistic show that the delivery sizes are getting smaller and more fragmented concerning the B2B-sector (Business to Business) and the number of single deliveries and home deliveries is increasing concerning the B2C-sector (Business to Costumer). Reasons for these trends are internet-shopping in the B2C-sector and the electronic-sourcing in the B2B-sector. Moreover, often there is more than one delivery attempt in the B2C-sector.
The big problem in the small freight mobility is the last mile, especially in city centers. The cost of the last mile is 45% in arithmetic average. It ranges from 20% to 60% depending on the company (Grün & Gudehus, 2003). Typical problems of the delivery in the city centre are the parking situation, the traffic, one-way streets and pedestrian areas. Concerning the parking situation especially in shopping streets and also in housing areas there are no free parking areas for the delivery service and so the car has to park in a second line. Sometimes this is tolerated, but sometimes the delivery service has to pay penalties for wrong parking. Concerning pedestrian areas the delivery services have to take care of the time slot for delivery. (Bogdanski, 2014)

1.1. Main idea of the project

The aim of the following project is to reduce traffic density by using a prospectively integrated system for autonomous general cargo and luggage and package transport. Simultaneously promoting public passenger traffic by developing a system for public freight traffic. Passengers will be getting rid of their luggage and passenger traffic and freight mobility are going to be installed at the same time. As a result the quality of life will increase and the environment will be perserved. In order to realise these goals, the research project smartBOX will provide concepts regarding the following system components:

- Conception of a standardised container with an intelligent control system and user security access (=the "smartBOX").
- Development of a pool system in order to provide availability, exploitation and control of the smartBOX regarding B2B as well as private passenger traffic by using electronic tracking&tracing methods and web-based communication technologies.
- Conception of extensively used vandalism proof pick-up and dropping terminals in public areas, as well as housing complexes. Adaption for freight transfer in the B2B sector.
- Conception of an encroached, intermodal transport system which will realise and bundle transport requirements in order to prevent multiple trips.
- Conception of IT-functionality by considering transparency and data privacy for decentralised autonomous subsystems.
- Conception of business models to provide favourable and distance-related transportation rates, cover service-provider expenses and combination with presently used systems.

[1] Corresponding author: petra.matzenberger@tuwien.ac.at

1.2. Statement of purpose

The main topic of this paper is the terminal. We found out that customers would be most satisfied if the luggage service is near one's residence. Best option to fulfil this demand would be a terminal. On the one hand, this terminal could be near one's residence door, but on the other hand it could also be at a train station instead of the current luggage deposits. An aim of the project "smartBOX" was to find out what a terminal should include and look like for the customer. Moreover, a test was conducted with customers with different kinds of luggage and different heights. The conclusion was that the optimal height of a lockbox for the terminal in this case depends on the luggage. By the way, most of this paper is based on the internal project results of the project "Smartbox" and a project called "Store and Go+".

2. Method

The method to get a good view of potential customer's needs and demands was a survey in form of a questionnaire. For that reason people on the street in Vienna and Parndorf, a shopping area in Lower Austria, and in four post offices, in Vienna and Lower Austria, were interviewed during January and April 2015. There was also an online questionnaire.
The first part of the questionnaire included questions concerning demographic information and the persons' residences. Moreover, the participants were asked about the actual delivery services. The next part included general questions about the terminal and its design. The last part of the questionnaire included questions about a pickup and delivery station.
With the help of the results of the surveys, it was possible to get detailed information about the interest groups for the terminal and the logistics services as well as their needs and demands. Additionally, qualitative surveys were done with business proprietors to determine their interest in and demands for a terminal and the developed logistics services of the smartBOX concept. They also showed an interest in the service, especially to oppose the online trade. The results of the surveys provide a basis for the design of the whole system and for the evaluation of the new and operating systems.
This paper only includes the results of the survey concerning the terminal.

3. Results

3.1. General data

Altogether, 890 persons were questioned on the street in Vienna and Parndorf, a shopping area in Lower Austria, and in four post offices, in Vienna and Lower Austria. Most of them (80%) were between 18 and 59 years of age. The age group between 18 and 26 made up with 28% of all questioned persons the largest group. Concerning the gender, more male persons participated in the survey (57%). The most of the questioned persons were living in a city. Below is some more detailed information about main residence.

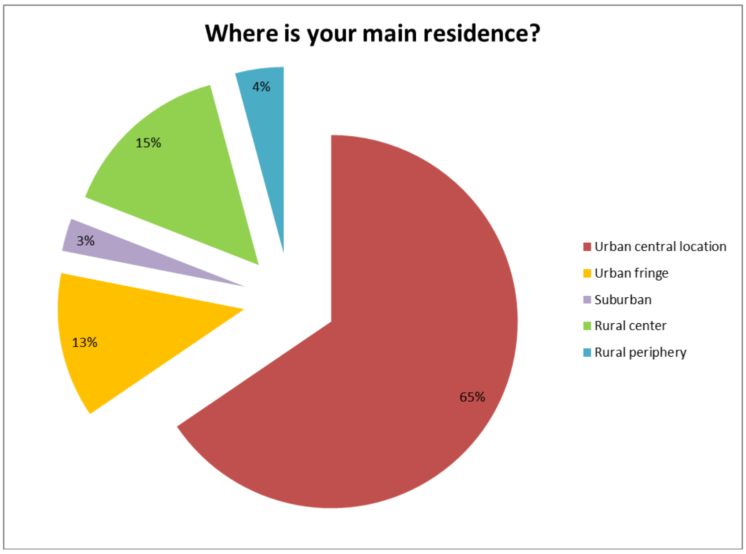

Fig. 1.
Representation of the main residences

42 % of the questioned persons were living in a flat with more than ten housing units and 24% in a flat with a maximum of ten housing units, 8% in a multi-family house and 26% in a one-family house.
In addition, the persons were questioned if there was normally someone at home during the day to accept a delivery. This question was answered with "yes" by 32% of the questioned persons, with "likely yes" by 15%, with "likely no" by 17% and with "no" by 36%.

3.2. Interest in the terminal

To find out the interest of the persons in a terminal to receive packages and also luggage, they were asked what their maximum effort would be to reach such a terminal. This interest is shown in Figure 2.

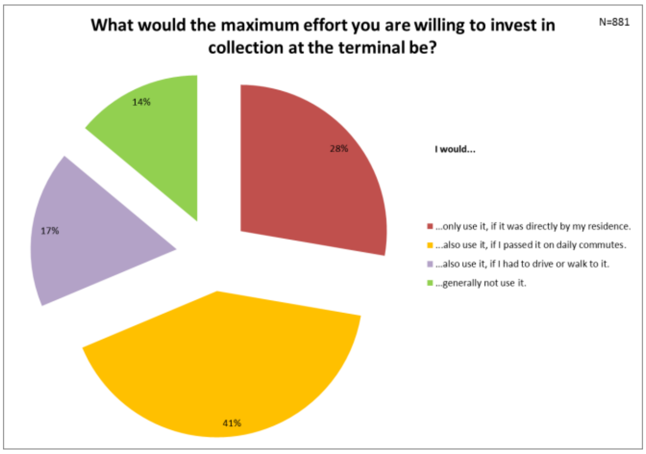

Fig. 2.
Representation of the interest in the developed logistics services

In addition, the interest in the developed logistics services of different groups was analysed. The results showed that older people were less interested in the new logistics services. Especially interested were persons, where no one is at the residences during the day (89%). Persons, who are satisfied with the actual situation, would use the terminal (23%) less than persons who are unsatisfied. Persons who never had problems with the actual service would use the terminal less (30%).
Concerning the setting of the principal residence people living outside a city centre or outside a village would render more to reach a terminal and use the logistics services (compare Fig. 3).

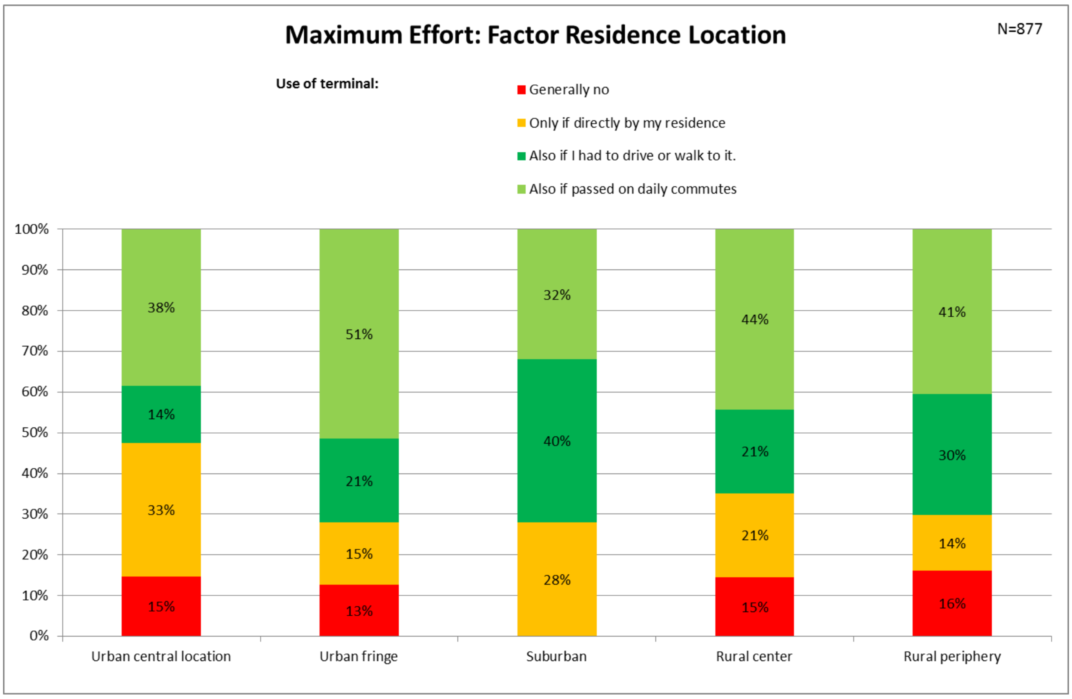

Fig. 3.
Representation of the interest in the developed logistics services of different settings of the principal residence

The survey showed that there were not many people who wouldn't generally use the developed logistics services. Counter-arguments for the terminal were:

- They prefered human contact.
- They were afraid that there are less jobs.
- It is too complex.
- The post office is next door.
- They are satisfied with the actual service.

Persons who were interested in the terminal were asked about the design of the terminal and how much time they would spend as a maximum. 35% of the questioned persons said, that they would maximally spend five minutes. 52% would spend 15 minutes and 11% 30 minutes. Only 2% would spent more that 30 minutes.

3.3. The design of the smart terminal

The questioned persons were asked what the terminal should look like in regard to different facilities. In general, following results, ordered by importance were shown:

1. **All parcel services (e.g. Post, DHL, DPD,…) should deliver to the terminal.**
   97% of the questioned persons thought that this is important or very important.
2. **24h-accessibility**.
   This was important or very important for 90%. It was less important for older people or for people, who are satisfied with the current situation.
3. **Good accessibility by public transport.**
   82% of the questioned persons said that this is important or very important. It was even more important for women.
4. **Roofing of the terminal.**
   This was important or very important for 74%. The interest was increasing with age.
5. **Well frequented, lively area.**
   66% thought that this is important or very important for the terminal's setting. Especially women and persons who were living in the city centre preferred such a setting. Interestingly persons who were living outside a village showed an interest in having the terminal in a busy neighbourhood.
6. **Free parking areas directly at the terminal.**
   This was important or very important for 59%. It was more important for men. Moreover, the interest is increasing with the age. The free parking areas were more important for people on the countryside or outside the city centre.
7. **The terminal should be inside a building.**
   This was important or very important for only 44%. The interest was increasing with age.

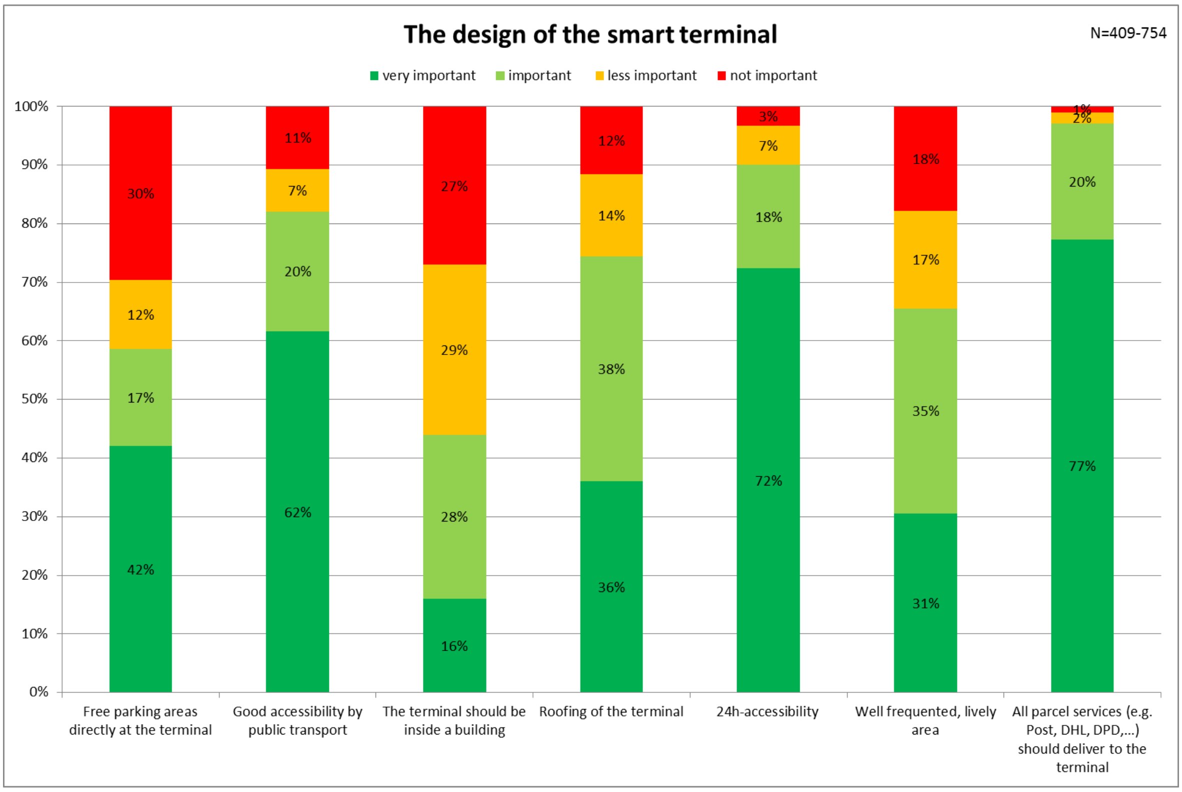

Fig. 4.
Representation of certain design aspects of the smart terminal

In addition, the people were questioned on how they would like to be informed if their package or parcels had arrived in the terminal. The most interesting notification options were SMS (84%) and mail (55%).
On a side note, 48% of the questioned people would pay extra for using the terminal. For 86% a registration at the provider would be no problem. 89% would welcome video control of the terminal.

3.4. Health related demands concerning lifting something

An essential aspect concerning health and ergonomics is the height of the terminal and the lifting process of the box. On the one hand, the terminal should be ergonomic for the customer and, on the other hand, also for the parcel service provider.
In another project of the Insitute of Transportation of the Vienna University of Technology it was evaluated what the optimal height and shape were to store packages. These results could be implemented in the developed logistics services because lifting a box like the smartBOX would be a similar process.
Concerning the results of the old project they agreed, in principle, with the idea that the preferred height is dependent on the transport method. That means that a trolley that rolls on the floor was best stored near the floor at the terminal. If someone is carrying his/her suitcase they preferred to store it in a height of 60 cm. The following figure shows the preferred storing height of different objects. There were two different shapes of the place where the object was stored.

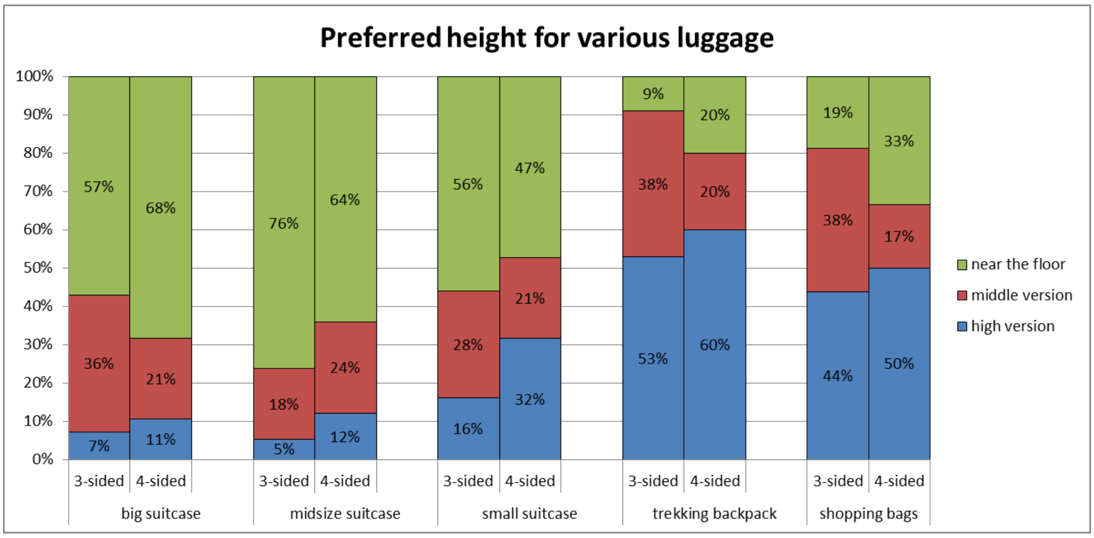

Fig. 4.
Preferred storing height of different objects

Summing up the results of the pioneered project the preferred height is dependent on the object and how it is transported. For example, if it is possible that the box is rolling on the floor, the preferred height would be near the floor. Surely, the weight of the object is an important factor. But no one would transport a one kilogram box on the floor. Therefore, the look and layout of the terminal is an influencing factor.

4. Discussion and Conclusion

Altogether 86% of the questioned persons would use the developed logistics services. This result shows that there is a great interest for such a logistics service. Also important to remark: Older persons (over 75 years) had a lower interest and are more satisfied with the actual situation than younger ones.
The customers have the following demands concerning the developed logistics services:

- The customers at least had to cross the station on their daily routes.
- A terminal should be reachable in 15 minutes (both ways combined).
- All service providers should be able to deliver to this terminal.
- In the city it is important that the station is easily reachable by public transport.
- On the countryside a free parking area is important.
- For the most the terminal should have roofing.
- The terminal should be in a lively, well frequented area, especially for women.
- A notification should be sent by mail or short message if the parcel was delivered.
- There should be no extra-costs for the service.
- People would pay extra for a longer storage at the terminal.
- A registration free of charge and a video control would be no problem for the customers.

Concerning the opinion of the commercial partners, there was an interest for the developed logistics services. For them the most important point is that the service has to be uncomplicated, safe and quick. If the service would comply with these points, the commercial partners would even support the service financially.

SAFETY OF NAVIGATION - COMPARATIVE ANALYSIS OF THE STATISTICAL INSPECTION REPORTS OF CROATIA'S HARBOUR MASTER OFFICE ZADAR OVER THE PAST TWO YEARS

Tatjana Stanivuk[1], Pero Vidan[2], Frane Prolić[3]
[1,2] University of Split, Faculty of Maritime Studies, Ruđera Boškovića 37, 21000 Split, Croatia
[3] University of Split, Faculty of Electrical Engineering, Mechanical Engineering and Naval Architecture, Ruđera Boškovića 32, 21000 Split, Croatia

Abstract: This paper outlines and analyses the annual statistical report on the performance of Croatia's Harbour Master's Office in Zadar and its Branch Offices. Statistical data have been processed with regard to the number of employees, number of registered ships, boats and yachts, as well as with reference to the cargo and passenger traffic through the ports under the jurisdiction of the Harbour Master's Office in Zadar, and number of search and rescue operations aimed at saving life and property at sea. A statistical analysis of the inspections carried out in 2015 has also been made. Statistical data for the year of 2015 have been compared with the 2014 data in order to achieve a better insight into the overall performance of the Zadar Harbour Master's Office and its Branch Offices.

Keywords: domestic and foreign ships, boats and yachts, statistical analysis of data, harbour master's office, branch offices, inspection and survey.

1. Introduction

Croatia is a maritime country with a very indented coastline and dense sea traffic. In addition to other issues, the Ministry of Maritime Affairs, Transport and Infrastructure of the Republic of Croatia is in charge of management and control of maritime demesne, seaports and vessels.
The Harbour Master's Office in Zadar, like all other Harbour Master's Offices in Croatia, operates under the jurisdiction of the Ministry of Maritime Affairs, Transport and Infrastructure. The Office consists of two main departments: the inspection department and the department for maritime traffic and search and rescue operations. This paper provides a statistical insight into the performance and efficiency of the two departments of the Zadar Harbour Master's Office and its Branch Offices.
The Zadar Harbour Master's Office includes 9 harbour branch offices whose authorised personnel carry out inspections of domestic and foreign vessels, both in ports and at sea, and keep records on the type, extent and nature of detected deficiencies. All these data are entered into the central computer system at the Ministry of Maritime Affairs, Transport and Infrastructure. The system stores information on all inspected ships, boats and yachts in the Republic of Croatia. Owing to the availability and transparency of the data which can be searched and selected through the categories of individual vessels or authorised employees, it is not difficult to make a statistical analysis and annual reports on the number of performed inspections, type and extent of detected deficiencies, number of detentions, number of search and rescue (SAR) operations, overall movement of cargo and passengers through the ports of the Republic of Croatia, etc. Supported by these information systems, the Ministry of Maritime Affairs, Transport and Infrastructure itself creates annual and other reports.
When inspecting foreign vessels, the inspectors in charge of the safety of navigation act exclusively in compliance with the international conventions and IMO (International Maritime Organisation) regulations governing the safety of navigation, safety of life at sea, environment protection, such as SOLAS, MARPOL, LOAD LINE conventions, etc. (Maritime Code, 2004; Maritime Code, 2007; Maritime Code, 2008; Maritime Code, 2011; Maritime Code, 2013)
When inspecting domestic ships, boats and yachts, vessels, the inspectors in charge of the safety of navigation act in line with the national laws and regulations such as Maritime Code, Maritime Demesne and Seaports Act, Regulation on the Inspection of the Safety of Navigation, Port Order Regulations, etc. (Maritime Code, 2004; Maritime Code, 2007; Maritime Code, 2008; Maritime Code, 2011; Maritime Code, 2013; Maritime Demesne and Seaports Act 2003; Maritime Demesne and Seaports Act, 2006; Maritime Demesne and Seaports Act, 2009)

2. Structure of the Zadar Harbour Master's Office

The Zadar Harbour Master's Office consists of the central office and nine branch offices distributed across the Zadar County, along the coast (Biograd na moru, Novigrad, Starigrad) and on larger islands: in the town of Pag on Pag Island, Preko on Ugljan Island, Sali and Božava on Dugi Otok, and on the islands of Ist and Silba. (Ministry of Maritime Affairs, Transport and Infrastructure - official web-site).

Source: Authors

The sea surface of the Zadar County covers a total of 572 NM (Table 1). Each office, including the central Harbour Master's Office and individual Branch Offices, covers a part of the area, as defined by the Law on Harbour Master's Offices. In addition to the jurisdiction area, Table 1 shows the number of employees for each branch office respectively, as well as the number of inspectors, authorised state officers, part-tome employees and vacancies with regard to the optimum number of staff as defined by the regulations. The Table clearly shows the difference in number of employees for the years 2014 and 2015 at all branch offices of the Zadar Harbour Master's Office, especially regarding the number of part-time workers whose number decreased in 2015, resulting in the corresponding number of vacant jobs.

The inspectors of the safety of navigation are entitled to carry out surveys and inspections of all vessels, whereas the authorised specialists are under the department for maritime traffic and search and rescue operations and are exclusively authorised for inspecting boats and yachts, both domestic and foreign. (Stanivuk et al., 2015)

Here it is necessary to point out that, besides the inspection of vessels, the department for maritime traffic of the Harbour Master's Office in Zadar is also in charge of other operations, such as search and rescue, signing on and signing off of the seafarers, maritime traffic control, etc.

3. Comparative method of statistical analysis of vessels in the area of Zadar Harbour Master's Office in 2015, compared to 2014

Table 2 provides the list of all vessels entered in the Register of shipping in the area of Harbour Master’s Office of Zadar by the end of 2015, compared with the year of 2014.

Source: Authors

The above Table 2 clearly shows that the Register of ships and yachts is under exclusive jurisdiction of the Harbour Master's Office in Zadar, whereas the Branch Offices are authorised only for the registration of boats.
With regard to the registered vessels in the years of 2014 and 2015, their number remained unchanged or was just slightly changed in most categories. However, the newly registered vessels saw a 60% drop, while the number of deregistered vessels decreased by 55.56%. These figures resulted from the fact that a large number of fishing vessels were already in exploitation in 2015 while some merchant ships, e.g. owned by the shipper Tankerska plovidba Zadar, were sold or deregistered due to their age and the global recession.
On the other hand, the number of newly registered yachts considerably increased from 2014 to 2015. The sharp rise of 361.7% resulted from Croatia's accession to the European Union, as the EU citizens were now able to enter their yachts in the Register of yachts of the Republic of Croatia under more favourable financial terms. As expected, most of the newly registered yachts have been used for personal non-commercial purposes.

Source: Authors

Table 3 presents the statistical values referring to the number of boats registered by 31 December 2015, compared to their number on 31 December 2014, for each boat category and for each organisational unit of the Zadar Harbour Master's Office, including the main and branch offices. The presented figures indicate an increase in total registered boats in 2015, as compared with 2014. The sharpest rise (58.6%) was experienced in the category of the newly registered boats, while the number of fishing boats (i.e. trawlers) plummeted by 27.7% (Tomašević at al., 2007).

As expected, the largest growth in the number of newly registered boats was experienced in the Harbour Master's Office in Zadar, given the fact that the city is home to three large marinas (Tankerkomerc, Borik and Sports port Uskok), as well as the nearby marina Dalmacija, Croatia's largest marina.

Apart from Zadar, a significant growth of the newly registered boats was experienced in the Branch Offices of Biograd, Preko and Pag, due to trends in nautical tourism and the marinas situated in the Branch Offices' respective areas: marinas Ilirija, Kornati and Šangulin in Biograd area, marinas Olive Island and Preko in Preko area, and marina Šimuni in Pag area.

There was only slight oscillation in the total number of boats registered in 2015 and 2014, i.e. this value remained constant.

4. Statistical overview of the movement of domestic and foreign vessels, passengers and cargo in the ports under jurisdiction of the Zadar Harbour Master's Office in 2015, compared to 2014

Table 4 presents the overall traffic of domestic and foreign vessels. In the ports under the jurisdiction of the Harbour Master's Office of Zadar, there was a decrease in traffic of domestic vessels and an increase in traffic of foreign vessels in the year of 2015, compared to 2014 (Stanivuk et al., 2015).

Table 4
Statistical overview of the movement of domestic and foreign vessels, passengers and cargo in the ports under the jurisdiction of the Zadar Harbour Master's Office for the year of 2015, compared to 2014

Source: Authors

It should be also pointed out that, compared to the year of 2014, there was a drop in the overall traffic of passengers and vehicles in the RO-RO (passenger) trade in 2015, whereas the same period saw a 12.5% (25,000 tons) increase in loaded cargo movement.

5. Inspections at the Harbour Master's Office in Zadar and its Harbour Branches in 2015, compared to 2014

This section provides a detailed analysis of the activities performed by the safety of navigation inspectors at the Harbour Master's Office in Zadar and the authorised specialists at the Branch Offices (http://www.mppi.hr/default.aspx?id=7397, 2016).

Source: Authors

As it might have been expected, Table 5 shows that the largest overall number of inspections was carried out in Zadar. The busiest harbour branch offices were the Branch Offices in Sali and Božava on the island of Dugi Otok. These offices jointly perform inspections of boats and yachts, especially in the dense traffic area of the Telašćica Nature Park, a popular destination of many nautical tourists, both foreign and domestic.
Compared to Sali and Božava, the Branch Office in Biograd n/m performs fewer inspections although much more boats and yachts have been registered in Biograd than in Sali or Božava. Unlike the harbour branch office of Sali, the harbour branch office of Biograd does not have a specialised vessel for operations at sea, where most inspections are actually performed during the nautical season.
It is also obvious that most of the ships were inspected by the Harbour Master's Office in Zadar, i.e. by the safety of navigation inspectors, and that most of the inspected ships were registered in Croatia. On the other hand, most of the inspected boats were foreign vessels.
The harbour branch offices in Novigrad, Pag, Ist and Preko did not perform any inspection due to the retirement of the personnel in the beginning of 2015. This situation also affected the overall number of inspections of vessels in the area under the jurisdiction of the Zadar Harbour Master's Office, so that there were fewer inspections carried out in 2015 than in 2014. The only inspection category that increased in this period was the inspection of foreign ships.
In addition to the inspections of vessels, the central and branch offices of the Zadar Harbour Master's Office carried out the inspections of the maritime demesne, seaports and safety of navigation facilities such as lighthouses, coastal lights, buoys, radio-stations, electronic and radar systems, and other safety of navigation facilities.

5.1. Overview of search and rescue operations

This section presents an overview of all search and rescue (SAR) operations carried out by the Zadar Harbour Master's Office and its Branch Offices, in cooperation with the national Maritime Rescue Coordination Centre, seated in Rijeka, for the year 2015, compared to 2014 (http://www.mppi.hr/default.aspx?id=7397, 2016).

Table 6
Overview of SAR operations performed by the Harbour Master's Office in Zadar and its Branch Offices in 2015, compared to the operations performed in 2014

TYPE OF DATA	HARBOUR MASTER'S OFFICE AND HARBOUR BRANCH OFFICES										TOTAL	INDEX	TOTAL
	ZADAR	BIOGRAD n/m	NOVIGRAD	STARIGRAD	PAG	PREKO	SALI	BOŽAVA	IST	SILBA	2015		2014

Boats saved	**14**	**0**	**0**	**8**	**0**	**0**	**0**	**0**	**0**	**0**	**22**	***110,0***	**20**
Total number of casualties	**4**	**0**	**0**	**1**	**0**	**0**	**0**	**0**	**0**	**0**	**5**	***500,0***	**1**

Source: Authors

It is rather important to emphasise that the overall number of SAR operations was lower in 2015 than in 2014 (see Table 6). It is highly commendable that, despite the reduced number of staff (see Table 5), the safety of navigation was increased owing to frequent inspections performed by the Harbour Master's Office in Zadar and its Branch offices. The cooperation of the Harbour Master's structural units should be pointed out as well. The harbour branch offices of Starigrad and Sali, for instance, engaged in joint SAR operations. Apart from the central Harbour Master's Office in zadar, the Branch Office in Starigrad was the busiest unit due to specific meteorological conditions prevailing in the area throughout the year (the most frequent threat to the safety of navigation being north-easterly gale-force Bura).
In addition to human lives, considerable property was saved in search and rescue operations in 2015. The value of the saved property was 10% higher than in the previous year.

6. Conclusion

In Chapter IX, the Maritime Code, the fundamental legal document governing the inspectoral supervision of the sea traffic and the safety of navigation in the waters of the Republic of Croatia, specifies the responsibilities of the safety of navigation inspectors and authorised specialists in Croatia's Harbour Master's Offices and their Branch Offices regarding the implementation of inspection surveys of domestic and foreign ships, boats and yachts.
The comparative analysis of the statistical data referring to the years 2014-2015 resulted in the following conclusions: the number of registered ships and boats in 2014 and 2015 did not fluctuate much, i.e. their number remained almost the same. However, the number of registered yachts saw a sharp rise, mostly due to the newly registered yachts intended for personal use and recreational purposes. With respect to the overall traffic of seaborne passengers and vehicles, there was a decrease in their movement in 2015, compared to 2014, whereas the cargo traffic grew over the same period.
The increasingly frequent surveys of ships, boats and yachts performed by the safety of navigation inspectors and the authorised specialists acting in line with the ever stricter national regulations and instructions of the Ministry of

Maritime Affairs, Transport and Infrastructure, gradually resulted in an increased safety of navigation, safety of human lives at sea, and marine environment protection.
Even though the number of employees at the Zadar Harbour Master's central office and its branch offices was below the optimum, the inspection surveys of the domestic and foreign ships, boats and yachts were carried out frequently and thoroughly. Violations of maritime regulations were detected and sanctioned with great diligence, in compliance with the Maritime Code, with the purpose of enhancing the safety of navigation, safety of life at sea, and marine environment protection.
Regular inspections and performance of the safety of navigation inspectors and authorised specialists at sea increased the awareness across the nautical population, i.e. participants in maritime traffic, especially in summer when more than 20,000 vessels were present in the area under the jurisdiction of the Harbour Master's Office of Zadar. This has been confirmed by the statistical data which show that, in the year of 2015, there were much less search and rescue operations and property salvage operations than in 2014.

ASPECTS OF DEVELOPMENT OF CONTINENTAL COMBINED TRANSPORT IN THE CZECH REPUBLIC

Jaromír Široký[1], Pavlína Hlavsová[2], Hana Vohanková[3]
[1,2,3] University of Pardubice, Jan Perner Transport Faculty, Department of Transport Technology and Control, Studetnstká 95, CZ-53210 Pardubice, Czech Republic

Abstract: This paper describes the current state of combined transport, and especially continental transport, in the Czech Republic, and aspects of its potential further development. The role of continental CT is particularly important in logistics chains, mainly in transporting palletised goods.

Keywords: combined transport, continental transport, logistics chains, development.

1. Current state of CT in the Czech Republic

Currently, only unaccompanied combined transport ("CD") is operated in the Czech Republic, mainly using ISO 1A containers due to the subsequent maritime transport. Moreover, swapbodies and intermodal road semitrailers are operated in the Czech Republic as well. However, their share in the total volume of CT is low. Statistical transport yearbooks show that the share of swapbodies and intermodal road semitrailers in CT in the Czech Republic in 2015 was 7.3% by gross tonnage transported (see Table 1 and Fig. 1).
It is the continental transport performed by other systems (not containers) that has a great potential. Since 2005, national transport of woodchips has been performed in special inland containers by integrated trains, and in 2012, sludge started to be transported in this way from North Moravia to Bohemia. In October 2005, international continental CT routes Lovosice–Duisburg were introduced, and in June 2006, Lovosice–Hamburg–Billwerder; these are mainly suitable for the transport of swapbodies and intermodal road semitrailers. Since 2010, CT transport operations with a regular transport of containers, swapbodies and intermodal road semitrailers have started to be performed on the routes Ostrava–Lovosice–Duisburg, Ostrava–Verona, Brno–Rostock as well. In 2012, transport started to be performed on another route Praha–Uhříněves–Duisburg, where ISO 1 containers are transported.

Source: Transport yearbooks 1995–2014, MD, adapted by authors

The ISO 1 containers are frequently used in continental CT transport, where it is necessary to change the gauge on the route. The ISO 1 containers are deployed on regular routes between ŠKODA AUTO Mladá Boleslav and Kaluga and Nizhny Novgorod (Russian Federation) – integrated trains. Moreover, ISO 1 containers are transported from the Paskov container freight station to Kazakhstan – groups of wagons. The results of these container continental transports cannot be established as carriers and CT operators consider these results for individual years as their trade secrets (ŠKODA AUTO Mladá Boleslav, Express-Interfracht, etc.). These national transport operations, not only those performed by ISO 1 containers, account for as much as 10% of CT, as estimated by the research team.
For the use of swapbodies and intermodal road semitrailers in CT to be significantly greater, there is no efficient incentive for road carriers and shippers. Even though road carriers own swapbodies (albeit often without rail transport authorisation[2]) and operate them in the Czech Republic, they only use them in the regular road freight transport. Moreover, road carriers mostly own shorter series C swapbodies, which is not ideal for CT due to higher reloading costs (one reloading of a series A swapbody corresponds to reloading of two series C swapbodies). The number of swapbodies used in the territory of the Czech Republic cannot be established; these are not freight vehicles and there is no national register and statistics. In CT, these transport units are mainly used by foreign road carriers and shippers (for

[1] Corresponding author: jaromir.siroky@upce.cz
[2] UIC railways and UIRR operators approved a plan of attributing ILU-Codes to transport units (swapbodies, intermodal road semitrailers). The plan started to be performed in July 2011, when UIRR started giving out ILU-Codes for marking these units with code stamps. Since July 2014, only ILU codes (swapbodies, intermodal road semitrailers) and BIC (ISO 1 containers) have been accepted. It is expected that after a 8-year transition period since the introduction of ILU-Codes (July 2019), all transport units are to be equipped with the new code stamps. Presently (March 2016), 7 Czech entities are registered in the ILU register.

instance DB Schenker, LKV Walter, DSV, DHL), even though swapbodies are very advantageous for CT (mainly for palletised goods). Due to their dimensions and construction, they cannot be transported on sea-going vessels – i.e. in maritime (intercontinental) transport.

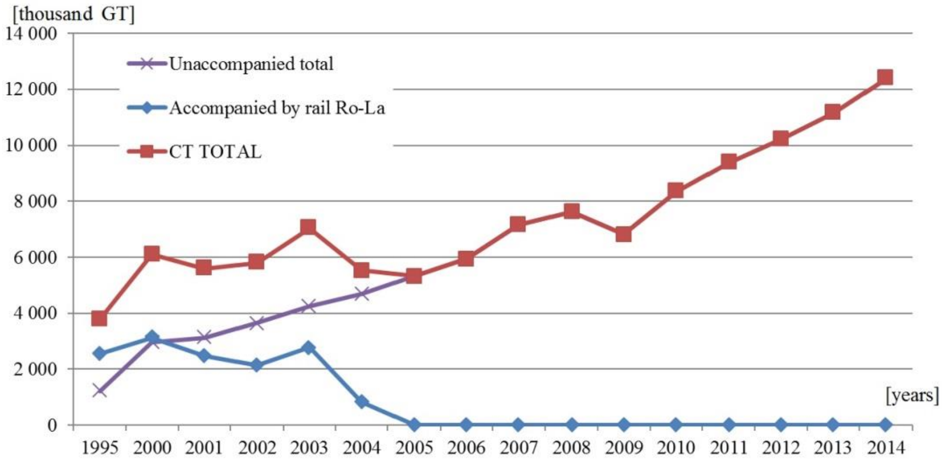

Fig. 1.
Total volume of CT in the Czech Republic between 1995–2014 [thousand GT]
Source: Transport yearbooks 1995–2014, MD, adapted by authors

The development of unaccompanied CT can be assessed as very positive. Its gradual increase is closely connected with the increase of world trade and the ever increasing maritime transport of ISO 1 containers mainly from/to Asia. As a result, the transport of containers by rail from/to large European ports (mainly Hamburg, Bremerhaven, Rotterdam, Koper, to a lesser extent also Rostock, Pireus and Trieste) increases as well, these cities being the key source and target points for international CT (see Fig. 2). That is why the number of direct integrated trains on the routes from/to ports is increasing and other subsequent routes are introduced from hub container freight stations in the Czech Republic by significant CT operators.

The use of individual CT systems is described in Table 2 and Table 3, showing the number of full and empty transport units in CT by rail in thousand GT and thousand TEU. It shows that the support of transport unit purchase between 2005–2010 resulted in an increase of transport mainly of intermodal road semitrailers by rail of several dozens of percent. Therefore, there is room for the use of transport units used in continental CT, especially intermodal road semitrailers or swapbodies. That is why the aim of this project is to provide methodology to further support the development of these CT systems.

2. Aspects of further development of continental combined transport

To achieve a greater use of CT, it is necessary to at least partially compensate the price differences compared to road transport. Before the costs for using a transport route are harmonised, a transport policy should be implemented that would at least in part eliminate these disproportions, ensuring more comparable conditions for CT. This is also in full accord not only with the White Paper on European transport policy (support of competitiveness of rail transport), but also with the results of the RECORDIT project (Real Cost Reduction of Door-to-Door Intermodal Transport) as part of the EU Fifth Framework Programme.

Yet another reason is the fact that the projects are not profitable in the initial phase as CT can only be efficient in directions where the streams of traffic are concentrated, and therefore it takes some time for a new system or CT route to gain market share. Only an integrated train with a capacity of 40 to 60 transport units usually starts to be profitable, its average utilization being at least 80% in both route directions.

It is not possible to make customers use a certain type of transport. For customers ordering shipping, several criteria may be of importance (speed of transport, shipment arriving in time, safety and reliability of transport, related services and their frequency); however, what is important is usually the price. Customers usually don't care that the safety of rail traffic is many times higher and most emissions are on a much lower level. This is related to the fact that these external costs are not internalised. In accordance with the White Paper, the average ratio of externalities in road and rail freight transport is about 4.5: 1. The internalisation of externalities is one of the most problematic issues in transport, and due to its complexity it has not been satisfactorily resolved either in the Czech Republic, or in any other EU state.

Not only the government, but also municipalities, regions, non-governmental organisations and other entities aim to support such types of transport that have the lowest negative impact on the environment. That is why the development of CT is supported, as emphasised by the EU White Paper as well. Therefore it is necessary to ensure a better integration of individual types of transport and at the same time, to provide for a significant potential transport capacity serving as connections in an efficiently managed logistics chain connecting all individual transport services.

The support of transport unit purchase depends on several other factors, dealt with by the authors separately below.

2.1. Reloading equipment for transport units in continental CT

Another significant factor is the high cost of investment necessary for implementing new CT system technologies and for construction or modernisation of infrastructure necessary for its further development. The modernisation of existing and construction of new CT container freight stations (meeting the requirements of the AGTC Agreement, Regulation of the European Parliament and Council 913/2010, 1315/2013, and 1316/2013), either independent or as part of public logistics centres, renewal or completion of rail fleet for CT, purchase of transport units and reloading equipment, and ship modification entirely depend on business plans; however, these are influenced by framework conditions.

It is to be noted that the development of continental CT systems is also related to technical and technological equipment of public CT container freight stations in the Czech Republic. Most publicly accessible container freight stations in the Czech Republic are equipped with reloading equipment including both spreaders for the reloading of ISO 1 containers, and spreaders with collets for vertical reloading of swapbodies and intermodal road semitrailers (see Table 3). Adding collets to reloading equipment is not very costly, as their price is around CZK 800,000[3] (purchase price of the Kalmar reloading equipment being around CZK 9 million). Considering the newly arranged supplier-customer relationships and the increasing number of transport operations, the price of collets as an addition to the reloading equipment is rather negligible.

Table 3

Overview of publicly accessible container freight stations with reloading equipment with collets in the Czech Republic (as of 06/ 2016)

Operator/owner	Container freight station	Number of reloading mechanisms with collets
ČD-DUSS, Terminál, a.s.	Lovosice	2
Rail Cargo Operator – CSKD s.r.o.	Mělník port Přerov	3 1
Terminal Brno	Brno-Horní Heršpice	2
METRANS, a.s., Praha	Česká Třebová Nýřany (near Plzeň) Praha-Uhříněves	1 1 2

[3] It is very demanding to operate the additional collets – the reloading equipment is not fully synchronised to manipulate with the device, i.e. the reloading must be performed by more workers and it takes a longer time. Additional collets reduce the carrying capacity of the reloading equipment by 1–1.5 t. It also usually takes several weeks to equip the reloading equipment with these additional collets. The purchase of a new reloading equipment is much more costly and the purchase time is very long (several months), as it not only depends on the manufacturing of the equipment, but also on the delivery, mounting and putting into operation.

Operator/owner	Container freight station	Number of reloading mechanisms with collets
	Šenov (near Ostrava) Želechovice (near Zlín) Ústí nad Labem	1 1 1
Star Container s.r.o., Mělník	Mělník port	1
AWT, a.s., Ostrava	Paskov (near Ostrava)	3

Source: Rail Authority, adapted by authors

The equipment of container freight stations for reloading of not only containers, but also swapbodies and intermodal road semitrailers is very important. The use of the particular transport unit is related to the number of manipulations during reloading at container freight stations (see Table 4). To compare the prices of reloading, articulated vehicles and road trains are considered. For containers, the use of articulated vehicles is considered (one ISO 1 A container or two ISO 1 C containers) or road trains for two ISO 1 C containers. For swapbodies, articulated vehicles are considered (one A swapbody – very rarely transported in the Czech Republic) or road trains for two C swapbodies. During reloading at the container freight station, the road set brings the transport units to a lay-by, and then the reloading from the lay-by to railway wagons takes place (or reversely). At the container freight station, the transport unit is thus reloaded twice. For C swapbodies and 1C ISO containers, it is necessary to account for a double number of manipulations (for road sets). Therefore even the number of manipulations in these types of transport unit is an important factor as the price of reloading increases. For intermodal road semitrailers, only one manipulation is considered[4] during reloading at the CT container freight station, whereas for ISO 1 A containers[5] or A swapbodies, there are two manipulations[6]. In collection or distribution of transport units to/from the container freight station, the types of manipulations with the individual units are not recorded for statistical purposes. Therefore in determining the price of manipulation, the above mentioned numbers of manipulations are taken into account.

Table 4
Number of manipulations at CT container freight stations for selected transport units

Transport unit	Number of manipulations at container freight station	Costs of one manipulation [EUR]	Costs of reloading of transport unit for articulated vehicle / road train [EUR]
ISO 1 A container	2	23	46
ISO 1 C container	4	23	92
A swapbody	2	25	50
C swapbody	4	25	100
Intermodal road semitrailer	1	32	32

2.2. Length and capacity of CT train

It is also necessary to point out the influence of CT train length and capacity. Presently, CT trains being around 550–630 m long (including the length of the power unit – 20 m) have a capacity of around 71–92 TEU. However, this value depends on the number of individual railway wagon series and their combinations. Individual CT operators in the Czech Republic use different series of railway wagons (for the transport of containers, swapbodies, intermodal road semitrailers). The following Table 5 illustrates the main series of railway wagons used in CT in the Czech Republic and shows the capacities of train sets in TEU for train length of 550–750 m (taking into account the recommended length of train of 740 m in accordance with Regulation 1315/2013).

Table 5
Capacity of CT train of a length of 550–750 m in different railway wagon series [TEU]

Railway wagon			Length of train [m]					
series	length [m]	capacity [TEU]	550	600	650	700	740	750
Sggrss	26.4	4	80	88	96	104	112	112
Sgnss	19.7	3	81	90	96	105	111	114
Sggmrss	29.6	4	72	80	84	92	100	100
Sggnss 80´	25.9	4	84	92	100	108	112	112

[4] During reloading of intermodal road semitrailers at the container freight station, the semitrailer is put on the lay-by upon arrival of the articulated vehicle at the container freight station. The actual reloading of the intermodal road semitrailer on a railway wagon (and reversely) is performed using reloading equipment, being considered by the container freight station operator as one manipulation.

[5] As it is possible to store ISO 1 A containers (or ISO 1 C containers), they are sometimes manipulated with at the container freight station. These technological manipulations are not counted as manipulations.

[6] During reloading of ISO 1 A containers or A swapbodies at the container freight station, the transport unit is put on the lay-by by the reloading mechanism upon arrival of the articulated vehicle at the container freight station. The actual reloading of the transport unit to a railway wagon is performed by the reloading mechanism and is counted as another manipulation (i.e. there are two manipulations).

Sdggmrs	34.2	4.8*	76	81	91	96	100	100
Sdggmrss TWIN	34.2	4.8*	76	81	91	96	100	100

Note: the capacity of 4.8 TEU corresponds to transportation of 2 intermodal road semitrailers on 1 railway wagon.
Source: authors

The length of train stated above includes the length of the power unit of 20 m. The individual combinations are not mentioned here as they are different for different CT operators. It is obvious from the overview that using a train with a length of up to 750 m (in accordance with AGTC Agreement recommendations), or 740 m (in accordance with Regulation 1315/2013), the capacity of the train set increases by approximately 30 TEU, which is very positive in economic terms. However, it is necessary to take into account that using a 750 m long train is very advantageous from the economic perspective, but very problematic from the operational point of view as in the Czech railway network, there are very few intermediate railway stations, at which overtaking or crossing of trains of such length would be possible on running tracks. That is why trains of such length cannot be counted on as of yet. The researchers suggest to use trains with a length of 650–700 m.

2.3. Support of CT abroad

In the EU, the support of combined transport is established by the Combined Transport Directive (Council Directive 92/106/EEC). The Directive aims to support certain types of combined transport eliminating authorisation procedures and quantitative restrictions for certain types of combined transport, clarifies the non-application of restrictions on road cabotage in road transport, and provides financial support for certain types of CT by means of tax incentives. In accordance with the provisions of the Combined Transport Directive, the combined transport of goods is to meet several specific criteria, mainly as to the type of transport units and distances.
The Combined Transport Directive is complemented by several other EU provisions, such as the directive regulating the weights and dimensions (Directive (EU) 2015/719 amending Council Directive 96/53/EC) laying down for member states to allow the movement of heavy duty intermodal transport units on the road, where they are used in CT. Moreover, the EU provides financial support to projects related to combined transport.
In line with the general EU transport policy, the aim of the provisions is to reduce the share of road freight transport and to support more environmentally friendly modes of transport with better energy efficiency. CT is supported in four main areas:

1. Internalisation of external costs in all modes of transport to provide adequate price signals to users, operators and investors. Social and environmental costs of transport should be paid taking into account its polluters.
2. Greater share of targeted investments in infrastructure to allow for better links between individual modes of transport.
3. Better use of information (on transport, capacity, availability of infrastructure, cargo and vehicle position).
4. Direct support of intermodal transport, as laid down in the Combined Transport Directive (Council Directive 92/106/EEC) aiming at increasing the competitiveness of combined transport.

What plays a crucial role in the development of CT in individual EU member states are the legislative regulations of this support, i.e. either laws or regulations. Before these provisions are issued, they are usually discussed with EU institutions. Even though the form and content of the individual ways of support are different, there is one common aim: to harmonise costs between direct road transport and CT.
In 2011, the European Commission presented a new plan of the European core multimodal network (it is to present instructions, schedules /road maps/ and financing plan of the TEN-T Trans-European network). EU financial means from TEN-T funds, cohesion fund and structural funds are to be used conceptually, and therefore they will be provided within a single framework.
In January 2015, the final report of project FV355/2012/MOVE/D1/ETU/SI2.659386 (Analysis of the EU Combined Transport[7]) was presented in Frankfurt am Main. Besides the actual analysis of CT systems in individual EU member states, the report also covered the support of CT in individual states. The support of CT was treated from two perspectives. The first one was the history of support in different countries or different projects and its impacts on the development of CT. The second one were recommendations for further support of CT development in the EU. The support should be provided in the following areas:

- subventions for the construction and modernisation of CT terminal infrastructure;
- subventions for the purchase and modernisation of CT reloading equipment;
- subventions for the construction of CT terminal allowing for non-discriminatory access of the operator to individual terminal users;
- creation of the Single European Transport Area as the core network of strategic infrastructure;
- moreover road vehicle parameters in different member states should be harmonised so that it is possible to use the option of a greater weight of shipments in international transport than in national transport (increase from 40 t to

[7] Project FV355/2012/MOVE/D1/ETU/SI2.659386 called Analysis of the EU Combined Transport was carried out by KombiConsult GmbH (Frankfurt am Main), Intermodality Ltd (Lewes), PLANCO Consulting GmbH (Essen) and Gruppo CLAS S.p.A. (Milan). The complete final report is available at: http://ec.europa.eu/transport/themes/strategies/studies/doc/2015-01-freight-logistics-lot2-combined-transport.pdf

44 t). Borderland areas will have better access to terminals abroad;
- long stays caused by transition to a different railway network will be eliminated using interoperable power units;
- harmonization of costs of access to transport infrastructure in the whole of Europe.

2.4. Logistics use of transport units in CT

In terms of transport of palletised goods (goods on Euro-pallets of 800 mm x 1200 mm) in continental CT, it is the A and C swapbodies or intermodal road semitrailers that are most advantageous for these, due to the inner space of the transport units (see Table 6). In both these transport units, it is possible to load up to 33 Euro-pallets (in one layer). It is by 37.5% more compared to the ISO 1 A container, even though in transporting these units by rail, an equivalent number of railway wagons is necessary. That is why for customers requiring the transport of palletised goods, these transport units suitable for continental CT are more advantageous than the use of regular maritime containers. Comparing these transport units, we can see that goods transported in three ISO 1 A containers[8] can be transported in only two A swapbodies or two intermodal road semitrailers. This results in a significant reduction of the number of transport units transported, and also the number of railway wagons used.

Table 8
Comparison of selected technical specifications in transport units

Transport unit	ISO 1 A container	Inland 45' PW container	C swapbody	A swapbody	Intermodal road semitrailer
length [mm] width [mm] height [mm]	12.192 2.438 2.896	13.716 2.500 2.896	7.820 2.550 2.700	13.600 2.500 3.000	13.600 2.500 3.005
number of Euro-pallets [pieces]	24	33	17	33	33
internal volume [m^3]	68	84	42	90	100
Empty weight [kg]	4.200	5.870	2.400	4.900	6.500–7.500
Maximum net weight [kg]	28.100	28.130	13.600	29.100	26.500–27.500
Maximum gross weight [kg]	30.500	34.000	16.000	34.000	34.000
Purchase price [CZK]	42.000	220.000	350.000	450.000	800.000

Source: CARU, Kögel, authors

At depots and logistics centres, terminal tractors are often used for the manipulation of swapbodies from lay-bys to loading platforms. These terminal tractors have to be purchased (the price of these tractors is around CZK 2 million). However, these tractors are not used in all depots or logistics centres. That is why the whole road train (lorry + trailer) is driven to the loading platform. However, this offsets the significant advantage of swapbodies (saving the driver's waiting time during unloading or loading).
On the other hand, when using the intermodal road semitrailers, the tractor drives the semitrailer to the loading platform and leaves it there. As in swapbodies, it then drives to the lay-by (or to another platform) and loads another intermodal road semitrailer. That is why there is no waste of time for the driver (tractor) during the loading or unloading. This is one of the significant advantages compared to ISO 1 containers that are mounted on the road semitrailers and can't be manipulated with during loading or unloading.
What also plays a crucial role is the purchase price of individual transport units suitable for continental CT. Table 6 describes basic technical specifications together with price for these transport units. For comparison, ISO 1A container parameters are mentioned here as well. In terms of price and inner volume, it is best to use A swapbodies. However, the companies using swapbodies asked mostly use C swapbodies (C745 or C782).

3. Conclusion

This paper describes the current state of combined transport, and especially continental transport, in the Czech Republic and aspects of its potential further development. The role of continental CT is particularly important in logistics chains, mainly in transporting palletised goods. This is also the main output of this paper. Within the Operational Programme of the Ministry of Transport, support will be granted for the construction of CT infrastructure (mainly CT terminals) and also for the purchase of new transport units for continental CT. There are many other factors that can influence the use of CT in the Czech Republic; however, these are beyond the scope of this paper.

[8] ISO 1 A containers are mainly used in continental CD in transport operations requiring a change of gauge (from 1435 mm to 1520 and vice versa) or in combination with ferry transport.

LOCATING CITY LOGISTICS TERMINAL BY APPLYING THE COMBINED QFD-VIKOR METHOD

Snežana Tadić[1], Slobodan Zežević[2], Mladen Krstić[3]
[1,2,3] *University of Belgrade, Faculty of Transport and Traffic Engineering, Serbia*

Abstract: Locating the city logistics terminal (CLT) is a strategic problem and various city logistics stakeholders are interested for its solution. All of them are generating the requirements that can be achieved through the definition of multiple criteria, based on which the location that most closely meets the expressed requirements is chosen. For the solution of the defined problems this paper proposes a model that combines the Quality Function Deployment (QFD) and Višekriterijumska Optimizacija i kompromisno Rešenje (VIKOR) methods. QFD method is used to establish the connections between requirements and criteria, as well as to obtain the criteria weights, while VIKOR method used for the evaluation of potential locations and selection of the best one in terms of considered criteria. The applicability of the proposed model is demonstrated by solving the real-life case study of locating the CLT in the territory of Belgrade.

Keywords: city logistics terminal, location, QFD, VIKOR.

1. Introduction

The city is the place of the largest concentration of economic and social activities, and logistics is very important for the sustainability and the economy of the city. With growing demands for a more efficient supply and environmental protection grows the interest in city logistics, i.e. goods distribution, and logistics systems of urban areas. Problems of supplying the city with goods and extracting materials from the urban areas are present and solved in accordance with varying degrees of economic, cultural, technological and other aspects of social development. The main problem is the lack of planning activities, comprehensive and long-term policy of city logistics. Urban planners' decisions are often inadequate, without the necessary research, analysis and insight into different measures and impacts.
The above mentioned problems and the complexity of logistics in urban areas, but also social, cultural, demographic characteristics of the city, architectural heritage, habits and attitudes of the population, caused the development of different conceptions of city logistics (Tadić et.al, 2014, 2014B). In a variety of different conceptual solutions logistics centers stand out. The concept is based on the channelling of goods and transport flows from different providers towards the logistics center and consolidated deliveries to the generators in the urban areas. In this way, logistics centers are becoming the central element of the system for the supply of goods and extraction of waste material. Depending on the size and characteristics of the cities, the number, size and location of logistics centers vary. Logistics centers play an important role not only in the supply chain, but also in planning of the city logistics as a whole, and their location has a significant impact on the performance of city logistics, i.e. on the large number of parameters of the urban environment and logistics flows (Tadić, 2014, Tadić & Zecevic, 2016). They are being established on the traffic-favourable locations on the outskirts of the cities, or in the immediate urban areas, and connecting the inbound/outbound flows, i.e. coordinating the flows of goods in the process of supply and extraction from the urban areas. Location of the city logistics terminal, in relation to the target market, significantly affects traffic and the environment, as well as the economic parameters of the adopted concept of consolidation (Tadić *et.al*, 2012).
Taking into account the specificity of the problem, different authors have dealt with the CLT location selection by applying specialized location models (e.g. Guyon *et.al*, 2012), multi-criteria analysis (e.g. Awasthi *et.al*, 2011, Tadić *et.al*, 2012), or their combination (e.g. Rhine *et.al*, 2011). In this paper the problem of locating CLT is solved using the combined VIKOR-QFD model. In general, the Quality function deployment (QFD) is a method for planning and development of the product/service which allows clear identification of needs and requirements of the users and development of a product/service which will meet the customer expectations to the greatest extent. It involves the formation of the House of Quality (HOQ) that illustrates the connection between user requirements (WHAT?) and qualitative characteristics (HOW?). Višekriterijumska Optimizacija i kompromisno Rešenje (VIKOR) method provides a compromise solution, i.e. achieves a maximum group utility and a minimum individual regret of the opponents, and in addition to considering the distance from the ideal solution, takes into account the degree of satisfaction of each criterion. The applicability of QFD and VIKOR methods are already proved, but there are not many papers in which these methods are used for solving the location problems. In this paper, the QFD method is used to establish the connection between the location requirements (WHAT?) and location criteria (HOW?) that will ensure the fulfilment of the requirements. The results are the criteria weights used in the second part of the model, in which the VIKOR method is applied for selecting the most appropriate alternative, i.e. potential location of the CLT.
The paper is organized as follows. Chapter 2 gives a detailed description of the proposed model and the steps for its implementation. Solving the case study of a CLT location selection on the territory of Belgrade is described in Chapter 3. Finally, conclusions and directions for future research are given at the end of the paper.

2. QFD-VIKOR model

This paper proposes a new hybrid model which is based on a combination of QFD and VIKOR methods for the solution of the defined problem, i.e. city logistics terminal location selection. QFD method is used to establish the connection between the location requirements and the location criteria based on which the defined requirements will be met. As a result of the QFD method, values of the criteria weights are obtained, by which the alternatives, in this paper city logistics terminal potential locations, are evaluated. VIKOR method is used for obtaining the final order of the alternatives. QFD and VIKOR methods are described below in more detail.

QFD method is created in Japan in the period between 1967 and 1972 as a result of a number of different initiatives (O'Connor, 1990), although Dr S. Mizuno (1994) is considered as the creator of this method because he gave the largest contribution to its development. QFD represents a well-structured, multi-functional method for adequate planning, developing, designing and manufacturing of any product or service based on user requirements. In general, the method involves creation of the House of Quality whose elements are user requirements on one side and technical (design, development) requirements (features)on the other. The goal is to perform prioritization of the user's requirements and obtain the weights of technical requirements, while maximizing user's satisfaction, based on the established connections between the user's and technical requirements.

QFD has a long history and a wide range of application in various fields (Chan & Wu, 2002). It is a powerful tool for quality planning, continuous improvement, decision making etc. In addition, the matrix of HOQ is an almost universal tool that can be used to prioritize most of the tasks in any field. QFD method has many advantages. It is user oriented, i.e. in the process of structuring the problem it takes into account users' requirements and feedbacks regarding the observed problem. QFD enables faster development of products or services because it focuses on the specific requirements of users who are clearly identified. It is focused on the teamwork, i.e. all decisions are based on consensus, which is achieved through discussion and exchange of views between participants in the process. Another advantage of the QFD method is documentation of all the data related to the realization of the process, which allows continuous verification of compliance with the users' demands and timely response in case of changes. The method also allows prioritization of user requirements while finding innovative solutions for these requirements, thus improving the process and achieving maximization of the effectiveness. In this way the user expectations can even be exceeded (Sularto *et al.*, 2015).

For obtaining product or service of the appropriate quality a variety of so-called quality control methods can be used, one of which is the QFD method. However, unlike some other methods such as Control charts, Process Capability, etc. which control the "manufacturing" process of the products or services, or methods such as Sampling plans, Dodge-Roming tables, OC curves, etc. which inspect the quality of the finished products or services, QFD method provides adequate quality in the process of development or design of the products or services (Scholz, 2013, Shahin, 2008). In addition, compared to some other methods, e.g. Taguchi method, Shainin method, Conformability analysis, Poka Yoke, etc., which also ensure the quality of the product/service development process, QFD method is more flexible, it can be easily modified, extended and combined with other methods and is more suitable for achieving the appropriate level of quality in terms of users, i.e. it is "closer" to users than other methods (Shahin , 2008). For the above reasons, the QFD method is chosen in this paper.

The VIKOR method was first proposed by Opricovic (1998) for multi-criteria optimization of complex systems with the Serbian name: VIseKriterijumska Optimizacija i kompromisno Resenje (meaning multi-criteria optimization and compromise solution). The VIKOR method is convenient for the selection problems because of its stability and ease of use with cardinal information. Another advantage is that it considers the lowest performance rating with respect to a specified criterion (Tsai *et al.*, 2011). The method focuses on ranking and selecting from a set of alternatives against various, and in most cases conflicting and non-commensurable, decision criteria and determines compromise solutions for a problem. Here, the compromise solution is a feasible solution which is the closest to the ideal, and a compromise means an agreement established by mutual concessions. The obtained compromise solution can be accepted by the DMs because it provides a maximum group utility of the majority and a minimum of the individual regret of the opponent. The compromise solution can be the basis for negotiations containing the DM's preference by criteria weights (Opricovic & Tzeng, 2004).

Different MCDM methods can be used to rank the alternatives, but after comparing them the VIKOR method is chosen for solving the defined problem. The ELECTRE method has the capability to manage non-homogeneous variables and different types of criteria, but it often does not lead to the definition of only one solution emerging among the others but a subset of preferable solutions. Therefore, this method is considered more suitable for decision problems characterized by not many criteria and alternatives (Caterino *et al.*, 2008). The PROMETHEE I method has a clear approach to the decision problem and a degree of complexity depending on how the decision maker wants to model the preference function according to each criterion. However, the method very often does not lead to a complete ranking of alternatives, actually not solving the given problem. The version II of the same method, instead, always allows a complete ranking of options, but it requires a manipulation of the available information that does not always have a logical meaning (Caterino *et al.*, 2008). The TOPSIS and VIKOR methods approach the decision problem in a similar manner. They both define an ideal solution combining the best performances of the alternatives according to each criterion and perform ranking of the alternatives with respect to their distances from the ideal solution. However, the TOPSIS does not consider the relative importance of these distances (Hwang and Yoon, 1981). The highest ranked alternative by VIKOR is the closest to the ideal solution, while the highest ranked alternative by TOPSIS is the best in

terms of the ranking index, which does not mean that it is always the closest to the ideal solution. Moreover, the VIKOR method proposes a compromise solution with an advantage rate (Caterino et al., 2008, Opricovic & Tzeng, 2004).
The steps of the proposed model are described below, and the scheme of the proposed model is shown in Figure 1.

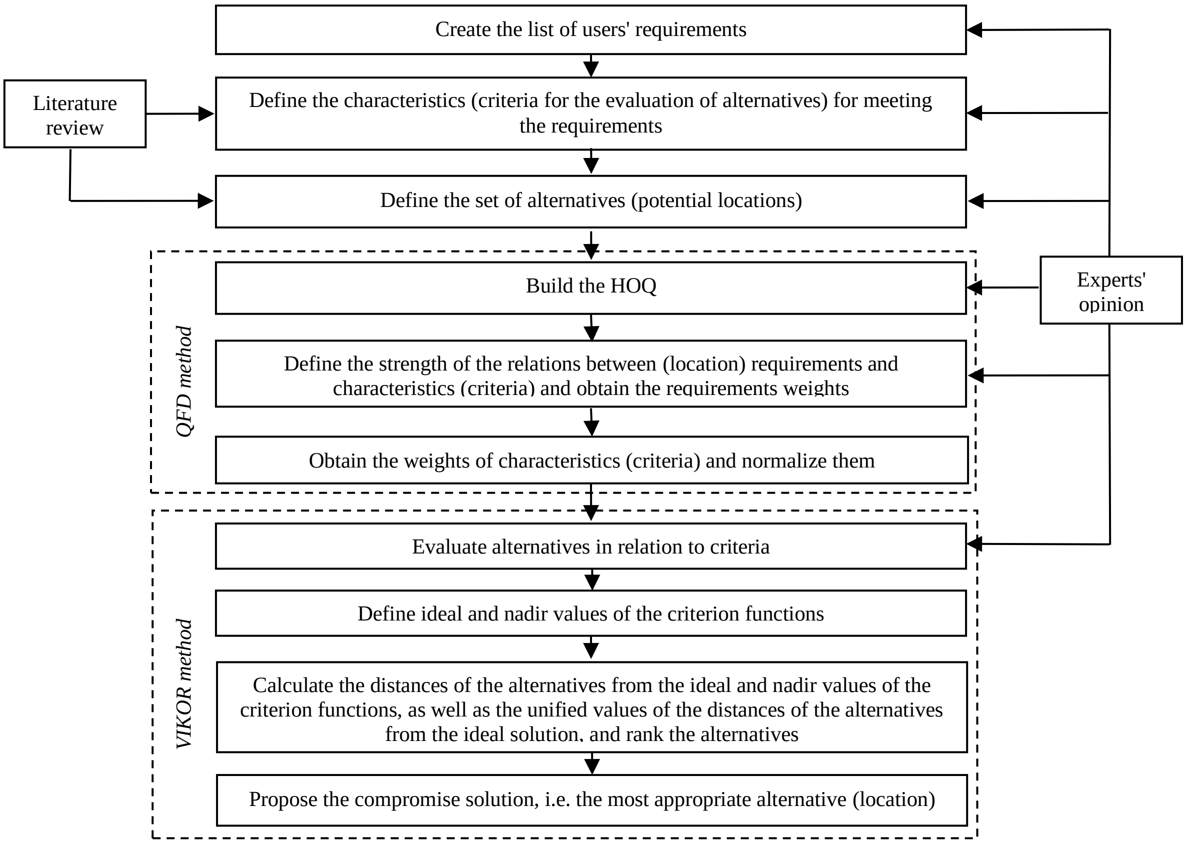

Fig. 1.
Proposed QFD-VIKOR model

Step 1: Define the problem structure. It is necessary to determine the structure of the requirements, in this paper requirements that city logistics terminal location must meet, a set of alternatives - potential locations of the terminal, as well as the criteria for selection of the alternative - location, which will ensure the fulfillment of these requirements by the defined alternatives and ensure the selection of one which will meet the set of requirements at most.
Step 2: Form the HOQ. House of quality is formed through the establishment of links between the requirements and criteria and consists of five main parts (Figure 2). The first part is a list of quality requirements, location requirements in this paper, that reflect the needs which a product or service in general, or location in this paper, must meet. The second part is a vector which refers to the values of the requirements weights, which determine the significance of each location requirement in this paper. The third part consists of qualitative characteristics in general, or criteria for locating the terminal in this paper, that must be taken into account in order to meet the defined requirements. The fourth part is a central matrix of relationships that establishes a connection between the (location) requirements and characteristics (criteria). It indicates the degree of satisfaction of each request in relation to each criterion. The fifth part consists of two vectors, the characteristics weight vector, or in this paper the vector of location criteria weights, indicating the overall level of influence of the criteria over requirements, as well as the normalized characteristics (location criteria) weight vector, which is used in the next phase of the model application as the weights of the criteria for locating the city logistics terminal.

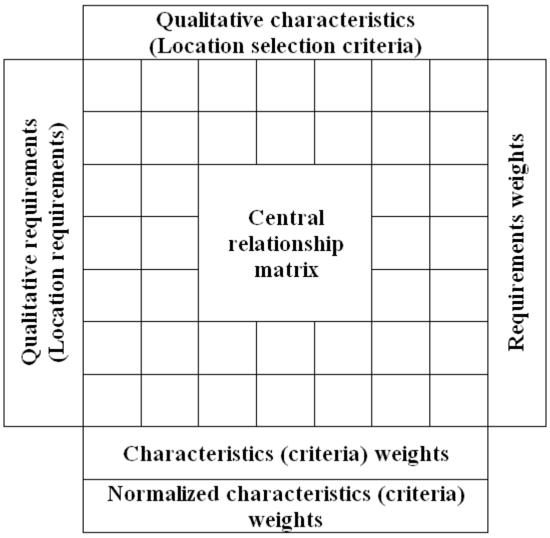

Fig. 2.
HOQ - House of Quality

Step 3: Fill in the central relationship matrix. The matrix is filled out based on the opinion of experts who are involved in the decision making process. The matrix is filled by entering the symbols "■" "◘" and "○", denoting a strong, medium and weak connection between the criteria and requirements, respectively, and indicate the degree of contribution of the criteria to the achievement of the defined requirements. The symbols are then transformed into quantitative values on the scale 4-2-1, i.e. the strong-medium-weak connections are being quantified into the given numeric values.
Step 4: Determine the requirements weights. The weight vector of the (location) requirements is obtained by evaluating the requirements by the experts involved in the decision-making process. In order to determine these weights, more detailed research that would involve various stakeholders (suppliers, customers, carriers, etc.) can be carried out and. The five-point scale shown in Table 1 is used in this paper to determine the requirements weights. In the case of requirements evaluation by the different interest groups or experts, the mean values of their scores are taken as the weights.

Table 1
Five-point scale for the evaluation of the requirements/alternatives

Linguistic assessment	Abbreviation	Numeric value
Weakly preferable/Bad	WP/B	1
Slightly preferable/good	SP/SG	2
Moderately preferable/good	MP/MG	3
Preferable/good	P/G	4
Very preferable/good	VP/VG	5

Step 5: Obtain the criteria weights. The importance of each criterion is calculated as the sum of the weighted evaluations of criteria influence on the implementation of the requirements (the values obtained from the central relationship matrix). Therefore, if *n* location criteria are taken into account in order to meet the *m* location requirements, the importance of each location criterion is obtained by using the equation:

$$w_j = \sum_{i=1}^{m} O_{ij} c_i \tag{1}$$

where w_j is the weight (importance) of criterion *j*, $j=1,2,...,n$, O_{ij} is the quantified evaluation of the relation between location requirement *i* and location criteria *j* from the central relationship matrix, and c_i is the weight of requirement *i*, $i=1,2,...,m$.
Weight values of each criterion are then normalized and such normalized values are then used as the criteria weights in the following part of the model. The following equation is used for normalization:

$$w_j' = w_j / \sum_{j=1}^{n} w_j \tag{2}$$

where w_j' denotes normalized value of the criteria weight.
Step 6: Evaluate the alternatives in relation to the criteria. By using the linguistic assessments, i.e. five-point scale given in Table 1, alternatives, or potential locations in this paper, are evaluated in relation to the criteria.
Step 7: Obtain the final ranking of the alternatives, i.e. potential locations, by applying the VIKOR method (Opricović, 1998).

Step 7.1: For the final ranking of the alternatives by applying the VIKOR method it is first necessary to normalize the quantified evaluations of the alternatives, i.e. potential location, in relation to the defined criteria. Normalization is performed using the following equation:

$$f_{kj} = \frac{x_{kj}}{\sqrt{\sum_{j=1}^{n} x_{kj}}}, k = 1,...,l, j = 1,...,n \quad (3)$$

where x_{kj} is the value of the evaluation of the alternative *k* in relation to the criterion *j*.
Step 7.2: After normalization, the best and the worst values of the criterion function are obtained, i.e. the ideal (f_j^*) and nadir (f_j^-) solutions are determined:

$$f_j^* = \max_k f_{kj}, k = 1,...,l \quad (4)$$

$$f_j^- = \min_k f_{kj}, k = 1,...,l \quad (5)$$

where f_{kj} is the normalized value of the preference of the alternative *k* in relation to criterion *j, j=1,2,...,n..*
Step 7.3 Afterwards, the distances (S_k) of the alternative from the ideal solution, and distances (R_k) from the nadir solution are calculated:

$$S_k = \sum_{i=1}^{n} w_j \left(f_j^{(*} - f_{kj}\right) / \left(f_j^* - f_j^-\right) \quad (6)$$

$$R_k = \max_j \left[w_j \left(f_j^{(*} - f_{kj}\right) / \left(f_j^* - f_j^-\right)\right] \quad (7)$$

Step 7.4: In the end, it is necessary to calculate the VIKOR values Q_k, for *k=1, ..., l*, as follows:

$$Q_k = v\left[\frac{S_k - S^*}{S^- - S^*}\right] + (1-v)\left[\frac{R_k - R^*}{R^- - R^*}\right] \quad (8)$$

where $S^- = \max_k S_k$, $S^* = \min_k S_k$, $R^- = \max_k R_k$, $R^* = \min_k R_k$, and *v* is the weight of the strategy of "maximum group utility". This means that if *v* is greater than 0.5, the index Q_k will strive towards the consensus of the majority, and if it is less than 0.5 the index Q_k will strive towards the negative attitude of the majority. By arranging the Q_k values in the ascending order, the final ranking of the alternatives is obtained.

3. Case study

The proposed evaluation model has been tested for locating city logistics terminal in the city of Belgrade, administrative and economic center of the Republic of Serbia. The problems of logistics in Belgrade have been solved partially and individually, without research and monitoring of the logistic parameters, and concerning the city logistics initiatives, only the ones of regulatory nature have been present. Restrictions are defined, adopted and implemented without the analysis of the situation and their impact (Tadić *et.al*, 2014c).
Logistics systems that support the implementation of goods flows are characterized by great spatial dispersion. Providers of logistics, transportation and distribution services were developing their own systems without adequate cooperation and coordination. For the purpose of improvement the efficiency of logistics activities, particularly in terms of impact on the environment, quality of service and competitiveness of the city and the region, different CL concepts are defined. One solution for the above problems would be the construction of a logistics center for the reception of long haul flows and consolidated delivery to the generator in the city. Given the very significant role of the logistics center in the realization of logistics flows, but also in planning the logistics and transportation systems of the city, it is necessary to determine the optimal location for its construction (Tadić *et.al*, 2012).
The first step of the CLT location selection by applying the proposed model is to define the structural elements of the problem. First, it is necessary to define the location requirements that are defined in this paper based on the literature review and the authors' experiences. Twelve requirements are defined and described in more detail in Table 2.

Table 2
Definitions of the location requirements

Location requirement	Definition
Convenient delivery to the terminal - Re_1	Main roads closeness, good transport infrastructure in the vicinity of the terminal, traffic congestion avoidance etc.
Users proximity - Re_2	The proximity of the users and the existence of adequate infrastructure to enable unhindered access to/from retails and other users of the terminal
Adequate space for development - Re_3	Large enough surface area for the development of all necessary subsystems, additional expansions, good geographical and geological characteristics, etc.
Stable supply of utilities - Re_4	Smooth and stable supply of water, electricity and other consumables, adequate utility infrastructure, availability of utilities, etc.
Preservation of the environment - Re_5	The tendency for the smallest possible influence on the environment (emissions, noise, vibration, etc.) by the processes within the terminal, as

	well as processes outside the terminal but generated by the terminal operations.
Low operating costs - Re_6	Low costs of terminal functioning and its daily activities (transport, storage, keeping inventory, ordering, loading, packaging, etc.).
Security of the goods and preservation of its quality - Re_7	Prevention of unauthorized and illegal usurpation of goods at any stage of goods flow, prevention of good quality degradation as a result of mechanical, weather, biological and other impacts.
Low investment costs - Re_8	Low costs of land acquisition, land development and preparation for construction, obtaining the necessary permits, constructing the facilities and systems, purchasing the equipment, etc.
Fast and reliable distribution - Re_9	Shorter delivery times, frequent deliveries, delivery of the right goods at the right place at the right time, etc.
Quick response to requests - Re_{10}	Ability to respond to the demands and needs of users in a short period of time, the possibility of rapid adaptation to new situations and problem solving.
Available labor force - Re_{11}	Closeness to the parts of the city with a dense population, the possibility of easy and quick access of workers to the terminal, favorable demographic structure.
Application of modern technologies - Re_{12}	Application of modern technologies in the processes of ordering, transportation, warehousing, transshipment, etc., with the aim of better realization of services by all parameters

For achieving the defined requirements, 27 criteria classified into five groups are defined (Tadić et.al, 2012): Land price - C1, Transport costs - C2, Users proximity - C3, Economic growth - C4, Traffic congestion - C5, Construction costs - C6 (Economic criteria); Transport infrastructure already built - C7, Multimodality - C8, Degree of facility establishment - C9, Utility infrastructure - C10, Expansion possibilities - C11, Location availability - C12, Safety of the location - C13 (Infrastructural criteria); Land ownership - C14, Populated areas proximity - C15, Compliance with spatial plans - C16, Compliance with regulations - C17, Traffic safety - C18 (Socio-political criteria); Weather conditions - C19, Geological conditions - C20, Hydrological conditions - C21, Topographic conditions - C22 (Natural criteria); Air pollution - C23, Noise and vibration emission - C24, Natural environment disturbance - C25, Influences of environment on goods - C26, Visual fitness into the environment - C27 (Ecological criteria). The evaluation criteria are defined on the basis of authors' experience and literature review. The following CLT potential locations (alternatives) are evaluated on the basys of the defined criteria (Tadić *et.al*, 2012): Pančevački rit - A_1, Luka "Beograd" - A_2, Ada Huja - A_3, Batajnica - A_4, Brodogradilište - A_5, Rakovica - A_6 and Kumodraž - A_7. Potential locations are defined by "Master plan of Belgrade 2021" as locations planned for the establishment of logistics facilities.

After defining the structural elements of the problem, the HOQ is formed in which the symbols ("■" "◘" and "○") represent the experts' evaluations of the importance of defined criteria for the achievement of the defined requirements. By applying linguistic assessments shown in Table 1, the experts also evaluated the significance of the location requirements. House of quality is shown in Table 3.

Based on the quantified values from the HOQ and by applying the equation (1), criteria weights are obtained (w_j), which are then by applying the equation (2) normalized and these normalized criteria weights (w_j') are shown in Table 4. Afterwards, alternatives are evaluated in relation to the defined criteria, by the experts, using a five-point scale given in table 1. These evaluations are also shown in table 4.

Table 4
Alternatives evaluations in relation to criteria

	w_j'	A_1	A_2	A_3	A_4	A_5	A_6	A_7

C_{24}	0,025	MG	SG	G	G	B	G	SG
C_{25}	0,019	SG	MG	SG	VG	VG	SG	G
C_{26}	0,004	MG	G	MG	MG	SG	MG	MG
C_{27}	0,019	B	G	B	B	G	B	SG

Evaluations of alternatives in relation to the criteria are converted into numerical values, which are then normalized by applying the equation (3). Based on the obtained values the ideal (f_j^*) and nadir (f_j^-) solutions are defined by using the equations (4) and (5). Afterwards, the distances of the alternatives from the ideal (S_k) and nadir solutions (R_k) are calculated using the equations (6) and (7). In the end, VIKOR values Q_k are obtained by applying the equation (8). For obtaining the Q_k values, the value of v=0.5 is used in this paper. Values of S_k, R_k, Q_k, as well as the final ranking of the alternatives are shown in Table 5. It can be seen from the table that the alternative A_4 - Batajnica is selected as being the most suitable location for city logistics terminal.

Table 5
Final ranking of the CLT potential locations

	S_k	R_k	Q_k	Rank
Pančevački rit - A_1	0.610	0.087	0.799	5
Luka "Beograd" - A_2	0.517	0.076	0.555	3
Ada Huja - A_3	0.611	0.093	0.887	6
Batajnica - A_4	0.251	0.062	0.065	1
Brodogradilište - A_5	0.539	0.057	0.310	2
Rakovica - A_6	0.716	0.087	0.913	7
Kumodraž - A_7	0.692	0.070	0.656	4

4. Conclusion

Locating the CLT is a long-term problem which must be addressed with a lot of attention as the selection of the appropriate location has a significant impact on the participants and subsystems of the city logistics. As the process of locating the CLT requires the participation of various stakeholders: local authorities, potential operators, trade associations, local logistics companies, potential users, etc., it is necessary to take into account their requirements and needs that can be met only by defining multiple location criteria, based on which the location that will be in accordance with the defined requirements can be selected. Accordingly, this paper proposes a model that combines QFD and VIKOR methods, whereby the QFD method is used to establish the connection between the location requirements and location criteria, as well as for obtaining the criteria weights, while VIKOR method is used for evaluating alternatives in relation to the defined criteria and selecting the most suitable alternative, i.e. CLT potential location. The applicability of the proposed model is demonstrated on the real case study of selecting the CLT location in the city of Belgrade. In the future research, the described problem and defined model could also be solved in the fuzzy environment, especially if we take into account that the assessment of the connection between the requirements and criteria, the importance of the requirements, as well as the evaluations of the alternative in relation to the criteria, are established based on the evaluations of the decision makers, who often give incomplete and vague judgments. In addition, the evaluations could be performed by the decision makers as direct representatives of various stakeholders (and for the unification of their evaluations and achievement of the consensus, the model could be extended with some additional method).

CONSIGNMENT STOCK CONCEPT IN THE CZECH REPUBLIC

Petra Vrbová[1], Václav Cempírek[2]
[1] *Faculty of Administration and Economy, University of Pardubice, Pardubice, Czech Republic*
[2] *Jan Perner´s Transportation faculty, University of Pardubice, Pardubice, Czech Republic*

Abstract: The concept of Consignment Stock is a very important logistic technique for short-term asset management as it is a completely innovative approach. This concept is crucial for helping manage inventories in which the supplier furnishes the inventory and maintains a stock of material in the buyer´s possession. This paper deals mainly with analysis finding of usage and share of the Consignment Stock concept usage in the Czech Republic and defining obstacles and gains before/during/after the implementation of Consignment Stockage. The analysis is based on a quantitative survey held in the Czech Republic.

Keywords: consignment stock concept, just-in-time, inventory management, vendor inventory management.

1. Introduction

The Consignment Stock (CS) inventory policy is becoming an important strategy that companies adopt to face new manufacturing and supply chain management challenges. A CS policy implies great collaboration between the buyer and supplier, pushing them towards a complete exchange of information and a consistent sharing of management risks (De Matta, 2014). The CS policy is already widespread in a number of industrial realities and it is obtaining raised consensus in both small and large contexts, since it offers a partial solution to the 'cycle time reduction' problem and avoids any shortage of materials through enhanced communication between suppliers and buyers. The technique in fact allows partners, the vendor and the buyer, to reduce management costs and increase their flexibility. In particular, the buyer virtually removes the procurement lead time, since the responsibility of the replenishment lies completely with the vendor, who keeps a stock of its property at the buyer's plant: the buyer uses the stock of materials according to his daily production requirements. Outsourcing of materials can easily incorporate the CS policy to enhance supply chain operations (Battini, 2010). CS is a logistic technique in which the vendor, instead of the buyer, is in charge of managing the buyer's inventory and triggering replenishment orders. This makes possible a partial suppression of the vendor's warehouse, which can be replaced by that of the buyer (Braglia, 2013). In particular, the buyer virtually removes the procurement lead time, since the responsibility of the replenishment lies completely with the vendor, who keeps a stock of its property at buyer's plant: the buyer uses the stock materials according to his daily production requirements (Abdel-Malek, Kullpattaranirun, Nathavanij, 2005). Consignment Stock (CS) is an innovative approach to supply and stock management, based on a strong and continuous collaboration between vendor and buyer to create a "win-win" situation, where both partners have equal gains (Battini, 2010). There is an obvious advantage for buyers. They have available stock and they can pay later for that. For sellers there is a very high certainty of supply and demand turnover when the stocks are with customers and the sale is almost guaranteed. And also they save space in their own warehouses. It also saves time to every part of the deal, because stock is being ordered by system which often uses min max method.

2. Basic elements of consignment stock

CS is a logistic technique in which the vendor, instead of the buyer, is in charge of managing the buyer's inventory and triggering replenishment orders. This makes possible a partial suppression of the vendor's warehouse, which can be replaced by that of the buyer. Consequently, it is possible to minimize both the ordering and the stock holding costs of the buyer, because materials formally owned by the vendor can be collected (that is, purchased) by the buyer only upon demand. On the other hand, the vendor gets visibility regarding the customer's demand and can use this precious information to schedule production and replenishment orders in an optimal way (Braglia,2013). In a CS policy, the buyer incurs stocking costs, since the materials are located in the buyer's plant, but does not sustain financing cost, since the item is purchased only when needed. In fact, since the item is formally purchased upon demand, the vendor sustains the financial costs of the capital immobilized until that moment. The vendor also receives a number of advantages. First of all, the average stock is reduced leaving more available space for stocking new items. Moreover, the vendor increases his production management flexibility since he is no longer constricted by consecutive close orders. For these reasons, a CS policy aims to reduce management and logistic complexity of the stocks and to ensure at the same time a constant availability of materials in order to eliminate stock-out risks. (Battini, 2010).
With regard to the basic description of the Consignment Stock concept, it is explained in Figure 1 below. Firstly, the Consignment stock itself is housed at buyers´ plants. Further, the buyer consumes delivered goods according to the daily production request. The information surrounding daily consumption data is exchanged with supplier. Additionally, vendor delivers the needed material according to the data exchange with the buyer enabling production planning. Finally, in the last step of the cycle, consignment stock refilling is performed by the vendor, including stock data update.

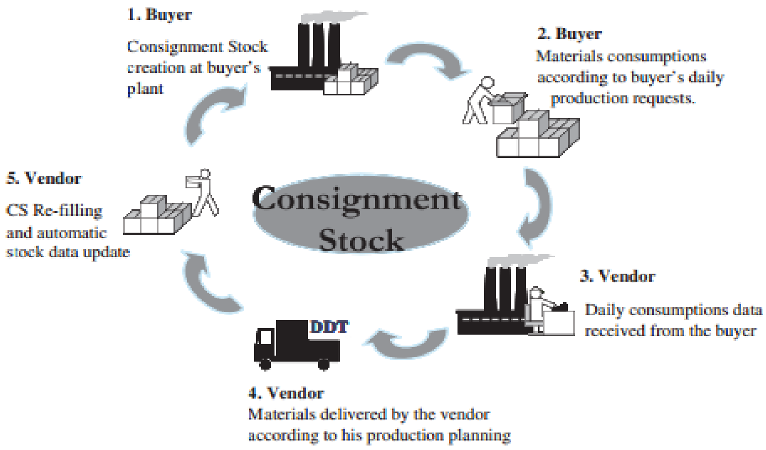

Fig. 1.
Consignment stock concept
Source: (Battini,2010)

Production and delivery of a schedule determined so as to minimize the total annual cost of the entire supply chain. Whenever something is produced, it is sent to the seller, who then sells the products in individual doses. Implementation of the consignment warehouse in cooperation seller and the buyer must be a fixed order. In order to avoid the production of the additional costs, should each machine to produce the maximum capacity (Braglia, 2013).

2.1. Consignment stock MIN a MAX concept

Supplier is responsible for keeping the buyer's inventory between a maximum (S) and a minimum level (s) and he also supports any additional cost due to stock-outs if his stock management strategy is not suitable to assure the required service level (Braglia,2013). In CS model a vendor can freely decide interval and volume of replenishment orders. The only requirement is that inventory in customer's warehouse stays between a minimum required level s and a maximum level S. Both s and S are agreed in a contract between vendor and customer (Valentini, Zavanella, 2003). The following Table 1. explains supplier's and customer's interests in stock level setting.

Table 1
Stock level related motivation for the supplier and the customer

Desired (s, S) and related motivation for supplier and the company		
	***s* level**	***S* level**
Supplier	↓ Keep as low as possible It represents a capital "frozen" in the company´s warehouse, which determines as opportunity cost	↑ Keep as high as possible It consists in a space offered by company to stock products, thus freeing space in own warehouses. Consequently, production flexibility may be increased
Company	↑ Keep as high as possible It is a sort of safety stock which enables a higher service level, whereas its economic burden is borne by supplier	↓ Keep as close as possible to *s* level There is a need for limiting the space occupied by the products and for reducing the problems linked to their management and handling

Source: (Valentini, Zavanella, 2003)

In Table 1 s represents the minimum inventory level allowed in the CS contract. A Supplier's motivation is to negotiate the s level as low as possible. The lower the s level is the less of a supplier's capital is potentially tied in the goods. In proportion, high s level means high safety stock for the customer. High s level is customer's advantage. S stands for the maximum allowed inventory level. While the supplier prefers a high S level to increase his or her operational flexibility, an S level close to s level is preferable for the customer. A Customer's total storage costs rise when more goods are stored in his or her premises (Rauvola, 2010). CS is preferably used for products characterized by constant consumption. Nonstandard products and prototypes are not to be included in CS programs (Valentini, Zavanella, 2003).

2.2. Benefits of Consignment stock concept

According to Graham (2015), first, the primary benefit that can be derived from a consignment agreement is that it allows the consignee to save money on inventory costs. As the consignee, you do not need to put money on the goods that you sell. You pay the consignor only after you have sold the merchandise. This could mean improved cash flow on the part of the consignee. Next, consignment can actually save you time because you do not have to wait for new inventory every time you run out of stock. Typically, the person or company that consigned the goods will automatically replenish your inventory right after you sell some or all of the consigned goods. It is in the best interest of the consignor to keep the agent well-supplied. Third, a consignment agreement is more convenient compared to a drop shipping arrangement where the retailer only takes orders and does not hold any inventory from the supplier. The consignee will have the merchandise on hand, easily accessible and ready for sale. Moreover, the consignee does not have to worry about goods running out of stock indefinitely, as resupplying the inventory happens regularly under a consignment setup (Graham, 2015).

Piasecky (2000) claims that the key benefit to the customer should be obvious; he does not have to tie up his capital in inventory. This does not mean that there are no inventory carrying costs for the customer; he does still incur costs related to storing and managing the inventory. So what's in it for the supplier? This is where the benefits may not be so obvious - or may not even exist. The supplier has the product or group of products for which believe they will sell and fall into the hands of end users mainly. The trick is that before we get products for end consumers, we need to get to the stock to the retailer. Traders are hesitant whether or not to store products because they do not have complete confidence in the suppliers do not want to invest money and risk to keep them in stock remained something that is not for sale (Lee, 2005).

Table 2
Consignment stock policy: benefits

Benefits for the buyer	Benefits for the vendor
1 Materials always on-hand	1 Optimization of transport
2 Reduced management costs	2 Optimization of production lot sizes
3 Procurement leads times drastically reduced (ideally eliminated)	3 Information on real consumption available (i.e., on-line data update or EDI interface)
4 Production mix more flexible	4 More space available
5 Immediate payment only of material quantities used daily	5 Long term relationship

Source: (Battini, 2010)

In Table 2, there are specified particular benefits separated from both a supplier's and a customer's perspective. With regard to benefits for the vendor, Battini (2010) deals mostly about the optimization of transport, of production sizes due to the fact that the entire planning of transport and lot sizes is to the domain of the vendor in accordance with real consumption data availability, as provided by the buyer. Furthermore, there are additional benefits for the vendor such as increased space availability and a long term contractual relationship. From the buyer's end, the main advantages are generally: materials are always on hand despite reduced management costs covered by vendor; procurement lead times are drastically reduced in case of optimal deliveries from vendor; the production mix is more flexible and payments are due only in the case of material quantities which are consumed.

2.3. Responsibility of vendor and buyer

Increasingly, competition has forced companies to seek stronger cooperation and strengthen the relations with its suppliers. One example of such cooperation is cooperation between two partners which will help to minimize costs and maximize profits of the entire system. Many researches showed that joint decisions business partners lead to the effective functioning before deciding if every man for himself within the same organization (Lee, 2005). These responsibilities affect the costs that each one of the players incurs in the future. Table 3 distinguishes the major responsibilities of Vendor and Buyer according to Zahran (2015).

Table 3
Summary of the responsibilities for the vendor and the buyer for consignment stock agreements

Responsibility	Vendor	Buyer
Product ownership	✓	
Physical loss, damage, theft, or defect		✓
Unused, unsold, or expired products	✓	
Inspection of delivered items		✓
Periodic inventory review, or audit	✓	✓
Inventory management		✓
Reporting, and order initiation		✓
Product pricing	✓	✓
Stock level management, and usage invoice	✓	
Payment by the due date		✓
Storage space requirement		✓

Source: (Zahran, 2015)

2.4. Risks associated to Consignment stock concept

Consignment stock may become disadvantageous if it brings about discrepancies in the records of both vendor and buyer. Table 3 above might refer also to risks associated to Consignment stock concept. Since for product ownership, it is vendor responsibility, he/she also has to deal with unused, unsold or expired products that might cause very high costs. The party supplying the stock faces the biggest risks under a consignment agreement. For one, the consignor will not receive any money until part or all of the consigned stock has been sold. In effect, the consignor's cash flow may suffer as more money is spent on manufacturing the goods, while cash coming in may be too slow to cover subsequent production runs. Next, the consignor may be exposed to higher product returns if the agents or consignees simply allow the goods to rot or become damaged in warehouses. After all, the consignee does not have any money invested in the consigned merchandise. Without a good profit sharing agreement, the consignee may not be too keen on pushing the consignor's products in the market. In addition, since resupplying or restocking the consignment inventory is done regularly, there is a risk of overstocking or duplicate inventories. This could be detrimental for both the consignor, who would have more goods sitting idly in the agent's warehouse, and for the consignee, who may spend more on inventory storage costs. Lastly, the record keeping systems of the party consigning the goods and the retailer or agent are not always the same (Graham, 2015). On the other hand, since buyer is responsible for storage of the materials, physical loss, damage, theft or defect, there is a huge responsibility of buyer and it is required. To provide inspection of delivered items by buyer as well. Buyer might avoid potential risks by periodic inventory review or audits. For the consignee, any misplaced item could mean paying for something that has not generated a profit. Meanwhile, inconsistencies on the consignor's side could lead to lost merchandise (Graham, 2015).

3. Methodology

There exists a plethora of research, studies, analyses, and formulas dealing with Consignment Stock, albeit mainly from theoretical point of view. By the way of contrast, there is little that is known about real usage - in terms of a practical adoption. It is therefore the main objective of this paper to specify and find out the share of the Consignment Stock concept usage in the Czech Republic and define obstacles and gains before/during/after the Consignment Stock implementation.

For the purpose of this paper, a quantitative survey was held in the Czech Republic as the main data collection source. The research was held in the period between March and May 2016 and obtained in the Czech Republic. A field survey was used to investigate the research questions and a structured questionnaire was utilized as the main data collection. Respondents/companies were selected both randomly and according to companies sampled in previous researches (71 companies). Companies were contacted as sampled from various industries and of different sizes and annual sales, in order to complete the questionnaire. Out of 118 companies addressed in various areas of business, 33 companies did not reply or refused to participate. Therefore, 85 replies were compiled.

Table 4
Respondents' overview

Industry	Total
Auto parts industry	6
Building industry	3
Ceramic industry	3
Chemical products	4

4. Key results

According to the research, a number of major advantages and disadvantages of Consignment stock concept adoption in the Czech Republic were identified. We were able to distinguish all the results below according to the buyer´s and supplier's point of view, separately.

4.1. Advantages of CS concept from the supplier's point of view

Table 5 demonstrates the main advantages of CS concept adoption from the supplier´s point of view. The major advantage can be identified as increased flexibility in deliveries (49%) as confirmed by almost half of respondents. Another advantage was determined to be the optimization of production sizes (25%). Due to the fact that each delivery is generally paid for following the actual consumption and consequently paid on a regular basis on contracted credit terms that may defer the capital expenditure for up to and over 3 months . One fifth of respondents also agreed that there is a huge advantage found in the diminished responsibility and time spent within orders and deliveries (20%).

Table 5
Advantages of CS concept from the supplier's point of view

Advantage	Nr. answers	% of answers
Optimization of production sizes	**25%**	21
More flexible deliveries	**49%**	42
Less responsibility and time /effort spent within orders and deliveries	**20%**	17
Others	6%	5
Total	100%	85

Source: (Author)

4.2. Advantages from the buyer`s point of view

Table 6 shows the most significant advantages of the Consignment Stock concept from the buyer’s point of view. Buyers find the following aspects as the most pervasive advantages of Consignment Stockage in almost equal measure – reducing the cost of business capital (18%), flexible response to a customer´s requests (15%), continuous availability of goods for customer (16%) and continuity of the production process (14%).

Table 6
Advantages of CS concept from the buyer`s point of view

Advantage	Nr. answers	% of answers
Continuity of the production process	12	**14%**
Flexible response to customer`s requests	13	**15%**
Reducing the cost of business capital	15	**18%**
Reduction of transportation and administrative costs	9	11%
Continuous availability of the goods for customer	14	**16%**
Customer payments after a real mat. consumption	11	13%
Inventory cost reduction and new form of production planning	5	6%
New way of partnership between customer and supplier	5	6%
Others	1	1%
Total	85	100%

Source: (Author)

4.3. Disadvantages from the supplier`s point of view

Table 7 shows the most significant disadvantages of CS from the supplier`s point of view. More than one third of all the respondents agreed, that the crucial disadvantage is the fact that suppliers need to deal with high bound capital in stock costs (35%) reserved for buyers. Furthermore, it is of great importance for suppliers to bear in mind risks and disadvantages associated with the need of regular inventory checking (22%), maintaining warehoused stock levels (20%), the entire responsibility for planning and delivery, etc. (21%).

Table 7

Disadvantages of CS concept from the supplier`s point of view

Disadvantage	Nr. answers	% of answers
High bound capital in stocks	30	**35%**
Keep a stock in warehouse	17	**20%**
Entire responsibility for production planning, delivery, etc.	18	**21%**
Regular inventory checking	19	**22%**
Others	1	1%
Total	85	100%

Source: (Author)

4.4. Disadvantages from buyers´ point of view

Table 8 shows the most significant disadvantages of CS from the buyer`s perspective. Buyers as respondents of this survey are mostly worried about the risks inherent with supplier reliability (40%). Trust, reliability and proper partnership are more than required in this kind of cooperation, due to the fact that in the event of low supplier reliability and delays, production stoppage and additional costs or penalties might ensue. More than a third of buyers listed as disadvantageous cases of claims and returns of goods (30%) as acquired goods would have already been invoiced and similarly, less responsibility for (and therefore, control over) deliveries (26%) which relates to the aforementioned risk of supplier reliability.

Table 8

Disadvantages of CS concept from the buyers´ point of view

Disadvantage	Nr. answers	% of answers
Risk of supplier reliability	34	**40%**
Claims, returned goods	26	**31%**
Less responsibility for deliveries	22	**26%**
Others	3	4%
Total	85	100%

Source: (Author)

5. Discussion

The concept of Consignment Stock is an innovative approach, requiring an established and solid cooperation and partnership between both parties to the transaction. Given the vast amount of research dealing with the mainly theoretical concept of Consignment Stock, the main aim of this paper was to discover practical advantages and disadvantages of the consignment stock concept from both the supplier's and buyer's perspective.

With regard to the supplier´s benefits, it has been determined that mainly the advantages listed centre around optimization of production sizes, increased flexibility in deliveries (more frequent and smaller deliveries) and less responsibility and time/effort spent within the ordering and delivery phases of the transaction (since the supplier is fully responsible for all these actions). From a buyer´s perspective, is the main benefits identified revolve around the reduction of the cost of operational capital, continuous availability of goods, and increased flexibility in responses to the customer´s request.

In determining supplier disadvantages, it was discovered that these mainly centre around the high bound capital in stocks (supplier invests capital into both goods in the consignment stock and also goods within their internal production and warehouse in order to be ready to supply once the reorder levels in the buyers´ consignment stock are reached); regular inventory checking, and the entire responsibility for production planning and deliveries. For buyers, the main disadvantages identified, mainly centre around the risks inherent with supplier reliability (in the event of which major additional costs could arise due to cessation of production, express transport costs, delays etc.), claims and returned goods (with the ensuing bureaucracy and time wastages in identifying goods that would have already been invoiced and considered as consumed), less responsibility for (and therefore control over) deliveries.

6. Conclusion

This article mainly focuses on analysis finding of usage and definition of obstacles and gains before/during/after the Consignment Stock implementation. For the purpose of this paper, a quantitative survey held in the Czech Republic was used as the main method of data collection, with a deeper focus on identifying advantages and disadvantages of the Consignment Stock concept itself for both suppliers and buyers. This paper is considered as just a part of the complete research dealing with risks related to the Consignment Stock concept implementation. This work helped to identify weak gaps that might be found as potential risks to avoid for the future implementation of Consignment Stock. Future work will focus on finding out what difficulties, obstacles and risks were found before, during and after the consignment stock implementation.

PRACTICAL APPLICATION OF THE METHODOLOGY FOR DETERMINING THE PERFORMANCE OF A COMBINED TRANSPORT TERMINAL

Ján Ližbetin[1], Ondrej Stopka[2]
[1,2] The Institute of Technology and Business in České Budějovice, Faculty of Technology, České Budějovice, Czech Republic

Abstract: This paper deals with the issue of overall performance of combined transport terminals. It is important to take into account the "compatibility" and how it ties with other elements of the terminal so that the transition of the intermodal transport unit over individual elements of the combined transport terminal is as smooth as possible. Practical application of the methodology was verified in the Prerov combined transport terminal which lies on the main railway line number 330 Prerov – Breclav, which is part of the second rail transit corridor in Czech Republic. The methodology consists of the optimization of all equipment and components performance in combined transport terminals comprising for example the handling equipment, reloading tracks, storage and reloading areas.

Keywords: combined transport terminals, handling equipment, optimization, storage, reloading, intermodal transport.

1. Introduction

Combined Transport Terminal (CTT) is the most important part of a combined transport infrastructure where various modes of transport come together (Fedorko et al., 2014), (Zając and Świeboda, 2015). It represents the point of change of the type of transport (rail, water, road) when handling intermodal transport units (large container, swap body, road trailer or entire articulated vehicle) and allows for cooperation of all concerned modes of transport (Stopka et al., 2014a), (Rogić et al., 2010).
The overall performance of the combined transport terminal is affected by the performance or by the parameters of the various elements of its internal infrastructure. Each element of the terminal should be designed to minimize the total time it takes to service road articulated vehicles and train units. It is important to take into account the "compatibility" and how it ties with other elements of the terminal so that the reloading the intermodal transport unit (thereafter referred to as ITU) over individual elements of the CTT is as smooth as possible. Practical application of the methodology was verified in the CTT Prerov. (Lizbetin, 2013), (Krile et al., 2015), (Siroky et al., 2010).

2. Performance Analysis of the Original Conditions in CTT Prerov

The combined transport terminal Prerov lies on the main railway line number 330 Prerov - Breclav which is a part of the second rail transit corridor. Near the CTT is the main road I/47 and I/55. There are plans to build the motorway D1 in the future (Kliestik, 2013), (Kubasakova et al., 2014).
At the time of the analysis (2013), the terminal had one single gantry bridge crane on tires PD 38 which worked as a principal means of handling and stacking and one side forklift truck BP 25, which worked as complementary. Both handling devices are able to handle large ISO containers only (Tadić et al., 2015). The storage area of the CTT is 2500 m^2. The usable length of the reloading tracks is 377 and 285 metres.

2.1. Performance of Handling Equipment

The performance of the handling equipment will be calculated separately for the crane and for the forklift truck. The parameters of the handling equipment are provided in Table 1.

Table 1
Technical parameters of the handling equipment in CTT Prerov

PD 38		BP 25	
speed	80 m/min	speed	300 m/min
span	12 m	weight	35 t
weight	38 t	lift height	8.125 m
lift height	8.5 m	turning radius	10.5 m
time for one loading operation	3 – 4 min	time for one loading operation	6 - 7 min

Source: authors
The time required for the loading operation of one ITU (large container - hereafter referred to as LC) located in the immediate vicinity of the crane is three minutes - T_1 (see Table 1). To calculate the handling the outermost

[1] Corresponding author: lizbetin@mail.vstecb.cz

ITU, we must first know the layout of the area under the crane which consists of one reloading track, one lane for articulated vehicles and one storage area (Siroky, 2011). Clearance of the crane allows stacking the LCs into three layers. Time T_2 is then calculated as follows:

$$T_2 = t_d + n_v * T_1$$
$$T_2 = 4.71 + 3 * 3 = 13.71\ min \tag{1}$$

Next, we determine the average handling time for one handling T_A:

$$T_A = \frac{T_1 + T_2}{2} = \frac{3 + 13.71}{2} = 8.36\ min \tag{2}$$

The calculations show that the hourly performance of the crane PD 38 is 7 handling operations. The shift performance of the crane (if the working day is 8,5 hours) is calculated as follows:

$$Q_O = \frac{T_{shifts} - (t_{breaks} + t_{waitingtime})}{T_A} = \frac{8.5 - (0.5 + 2 * 0.25)}{8.36} * 60 \cong 53\ LCs \tag{3}$$

The one side forklift truck BP 25 also allows stacking the containers in three layers in one row. The container can be handled on one side only. Reloading the container is therefore possible either to an articulated vehicle (travelling next to the vehicle), or by turning the car with the container at the specified location and unloading the container on the opposite side. Only the second option is possible in CTT Prerov. For these reasons, the time for one loading operation is extended by the necessary moves to places where it is possible to load or unload of LCs on to or off articulated vehicles or places that enable turning the vehicle.

$$T_1 = 7\ min$$
$$T_2 = t_d + n_v * T_1 = 1.26 + 3 * 7 = 22.26\ min$$
$$T_A = \frac{T_1 + T_2}{2} = \frac{7 + 22.26}{2} = 14.63\ min \tag{4}$$

The calculations show that the hourly performance of the forklift truck is 4 handling operations. Shift performance of the truck (if the working day is 8.5 hours) is calculated as follows:

$$Q_O = \frac{T_{shifts} - (t_{breaks} + t_{waitingtime})}{T_A} = \frac{8.5 - (0.5 + 2 * 0.25)}{14.63} * 60 \cong 30\ LCs \tag{5}$$

The overall performance of the handling equipment while taking into account the mutual interference of concurrent handling operations is about 80 loading operations per 8.5 hour shift.

2.2. Reloading Tracks

In the combined transport terminal in Prerov, there are two handling tracks nos. 405a and 407a with useful lengths of 377 and 285 metres. The reloading track is only the track no. 407a because the track no. 405a is under trolley wire. Therefore, it can only be used as a shunting (siding) track.
The layout of the tracks allows access of the driving car to the unit train from both sides. The total usable length of the two tracks is:

$$l_u = l_{405a} + l_{407a} = 347 + 255 = 602\ m \tag{6}$$

The handling track no. 407a can take 13 rail cars with an average length of 19.64 metres which can be loaded with 39 LCs. The handling track no. 405a can take 17 rail cars with the capacity of 51 LCs but these cannot be reloaded.

2.3. Storage and Reloading Areas

Storage areas at the CTT Prerov are currently divided into three parts with a total capacity of about 180 LCs. Along the reloading tracks is an area on which approximately 66 LCs can be stored in three layers. The other two storage areas are situated at the rear of the CTT, each with the capacity of about 60 LCs in three layers.
The total size of paved areas (storage and reloading area, internal road network) is about 4 200 m^2, out of which the storage area is:

$$S_{LC} = N_{LC} * s_{LC} * \frac{1}{\gamma} * t * \beta = 180 * 19.5 * \frac{1}{3} * 1 * 1.4 = 1\ 638\ m^2 \tag{7}$$

The size of the reloading area is established in two ways because it is influenced among others by the type of the handling equipment and, in the CTT, there are two different types of handling equipment.
The gantry crane on tires PD 38 needs two lanes with a width of 2 metres and in places where the crane rotates, it obviously needs an extended area (i.e. about 15 metres) for handling. When calculating the reloading area, we will not calculate with circular area, but for technical reasons, we will calculate with a square area. We will also presume that the length of the CTT is about 250 metres and the crane will rotate only at one end of the reloading area. The total reloading area for PD 38 will be as follows:

$$S_{PD38} = 2 * 2 * 250 + 15^2 = 1\,225\ m^2 \tag{8}$$

The one side of the forklift truck BP 25 needs the handling area of one lane with a width of 4 metres and its turning radius is about 8 metres. The truck can rotate in two ways, namely:

- Turning in a circle with a radius of 8 metres,
- Rotate using the so-called triangle that has at least two sides of a minimum radius of 8 metres.

However, since the fork lift is only used as a "backup" equipment in the CTT (in case of failure of the crane), we will not consider a separate reloading area for BP 25. Therefore, in the case of using the fork lift for reloading the LCs, the lanes for road vehicles can be used for handling.

2.4. Entrance Gate and Internal Road Network

Entrance gate in the CTT is designed for dispatching the road vehicles on the internal road communication with lay-flat road for two articulated vehicles waiting for dispatch, one of which is located directly on the road. (Lamacz, 2010) In the CTT, it is single-circuit system (direct access of road articulated vehicles to the place of reloading) used.
Local conditions permit driving the road vehicles around the reloading tracks only in one lane in both directions. Road articulated vehicles turn at the back of the CTT near the lay by and storage areas. The distance that articulated vehicles must travel in the CTT is about 500 metres. (Lizbetin, 2011) Internal road network in the CTT takes up an area of about 1 360 m^2, of which approximately 640 m^2 serves the forklift truck BP 25 for loading the trains. Assuming that the speed of the articulated vehicle in the area of the CTT is 20 kmph, we can determine the time the articulated vehicle spends in the CTT as follows:

$$T_V = t_D + t_M + t_C = 2 + (2 * 7) + 10 = 26\ min \tag{9}$$

Where; t_D: driving time of the articulated vehicle in the CTT, t_M : time of handling with LCs (unloading and reloading), t_C : time of inspection and commercial operations.
In the 8.5 hour shift, 17 articulated vehicles can theoretically be served. Technologically, however, it is possible to be commercially checking out one articulated vehicle while the other one is being loaded. The third articulated vehicle in the CTT would cause collision points. The total capacity of the internal road network is therefore about 34 articulated vehicles.

2.5. Summary of Current Performance of the CTT Prerov

The performance of the handling equipment for THE 8.5 hour shift is about 80 loading operations. The capacity of the storage area is about 180 LCs. The track system allows to handle a train with 90 LCs. The internal road network capacity is sufficient to handle 68 LCs per shift.
It follows from the above mentioned that the average daily output of the CTT Prerov is about 68 LCs (the road network is a limiting factor). The annual capacity is about 17 000 LCs.

3. Determination of the Practical Performance of the CTT Prerov after Reconstruction

Reconstruction of the CTT includes mainly construction works (extensions of paved areas designed for the handling and storage of the ITU, as well as the movements of road articulated vehicles; shifting of tracks so that handling with the ITU is possible on both tracks). The reconstruction will also include exchanging the handling equipment for more modern, more efficient and more universal ones (plans count on reloading the ITUs other than large containers) (Lamacz, 2010), (Stopka et al., 2014b), (Nedeliakova et al., 2015).

3.1. Reloading Tracks

After the construction work of the track system, the track no. 407a will be extended by 110 metres and the track no. 405a will be adjusted so that ITUs can be loaded and unloaded on this track as well. The total effective length of both tracks will then be:

$$l_u = l_{405a} + l_{407a} = 347 + 365 = 712\, m \tag{10}$$

After reconstruction, a unit train with 19 rail cars with the average length of 19.64 m which can be loaded with about 57 LCs, can be driven onto the loading track no. 407a. It will be possible to reload on this track as well. The capacity of track no. 405a will remain unchanged, i.e. 17 rail cars with 51 LCs. Therefore, after reconstruction of the CTT Prerov, it will be able to handle a full train with normative length according to the AGTC agreement (max. 700 m). The capacity of the reloading tracks will be 108 LCs per train.

3.2. Performance of Handling Equipment

After reconstruction, two reachstackers Hyster RS 46 will operate in the CTT. Their parameters are as follows:

- Speed: 350 metres per min,
- Load: 46 (resp. 36) tonnes,
- Lift height: 14.9 (resp. 13.4) metres,
- Time of loading operation (t1): 2 - 3 min.

To calculate the time of the loading operation with the outermost LC (T_2), it is necessary to know the arrangement of the LCs on the storage area. They will be arranged in blocks, each block consists of three rows of three layers (local circumstances do not permit stacking of more layers). Time T_1 is therefore two minutes and time T_2 is calculated as follows:

$$T_2 = t_d + n_v * T_1 = 0.57 + 6 * 2 = 12.57\, min \tag{11}$$

Average time T_A is then determined as follows:

$$T_A = \frac{T_1 + T_2}{2} = \frac{2 + 12.57}{2} = 7.29\, min \tag{12}$$

The calculations show that the hourly performance of the reachstacker Hyster RS 46 is 8 handling operations. Shift performance of the reachstacker (if the working day is 8.5 hours) is calculated as follows:

$$Q_O = \frac{T_{shifts} - (t_{breaks} + t_{waitingtime})}{T_A} = \frac{8.5 - (0.5 + 2 * 0.25)}{7.29} * 60 \cong 62\, LCs \tag{13}$$

Performance wise the same two reachstackers (the same types) will operate in the CTT which is why it is not possible to divide them as basic and additional. They will work equally, thereby shortening the travel distance of the vehicle by half. Therefore, the overall performance of the handling equipment in the CTT after reconstruction will be about 120 LCs per shift (8.5 hours).

3.3. Storage and Reloading Areas

The size of the reloading area in the CTT after reconstruction should be about 3 600 m^2. To eliminate the collision points of the two handling devices, this area should be divided into at least two blocks in order to allow the entrance of one of the handling equipment between the LCs which will free the area for crossing the other handling equipment (Xu et al. 2015). These gaps can also be used for temporary unloading the LCs which are stacked and need to be reloaded so that we can get to the LC we need (multiple handling) (Lizbetin et al., 2012). The total capacity of the storage areas is as follows:

$$N_{LC} = \frac{S_{LC}}{s_{LC} * \frac{1}{\gamma} * t * \beta} = \frac{3600}{19.5 * \frac{1}{3} * 1 * 1} \cong 553\, LCs \tag{14}$$

After the creation of two blocks (30*3*3 LC), the overall capacity would be extended to 540 LCs.
The reloading area is determined according to the usable length of the first longer track and the minimal necessary width required for safe rotation of the reachstacker:

$$S_{TA} = 400 * 15.6 = 6\ 240\ m^2 \tag{15}$$

The total size of the storage and reloading areas will be 9 840 m^2.

3.4. Entrance Gate and Internal Road Network

The entrance gate to the CTT is designed to dispatch road articulated vehicles on the internal road with a lay-by for six road articulated vehicles waiting for dispatching when one road articulated vehicle is standing on the road and one lane will remain passable at all times. In the CTT, the single-circuit system will be used (direct access of the road articulated vehicles to the place of reloading).
The road articulated vehicles will pass through the CTT in a one-way circuit. The distance the road articulated vehicles must travel in the CTT is about 850 metres. The internal road network in the CTT will cover an area of about 3 000 m^2, of which approximately 1 500 m^2 will go through reloading area. Assuming the speed of the articulated vehicle in the area of the CTT is 20 kmph, we can determine the time the articulated vehicle spends in the CTT as follows:

$$T_V = t_D + t_M + t_C = 2.5 + (2 * 2) + 10 = 16.5\ min \tag{16}$$

As two equivalent handling devices will work in the CTT, it will be possible to reload two road articulated vehicles at the same time and other two articulated vehicles can be commercially dispatched. Within an 8.5 hour shift, it will be theoretically possible to serve about 100 road articulated vehicles.

3.5. Summary of Performance of the CTT Prerov after Reconstruction

Performance of the handling equipment in an 8.5 hour shift is approximately 120 loading operations. The capacity of the storage area is about 540 LCs. The track system allows for handling a train with 108 LCs. The internal road network capacity is sufficient to handle 200 LCs per shift.
It follows from the above that the average daily output of the CTT Prerov after reconstruction will be about 100 processed LCs (loaded vehicles). The annual capacity is about 50 000 LCs (vehicles).

4. Evaluation of the Change in Performance of the CTT Prerov

Table 2 gives a summary of parameters and overall performance of the CTT Prerov before and after reconstruction.

Table 2
Technical parameters in CTT Prerov

	Status	
	Before reconstruction	**After reconstruction**
total paved area	4 223 m^2	11 360 m^2
storage area	1 638 m^2	3 600 m^2
performance handling equipment	80 lo*/ws**	120 lo/ws
total performance CTT	34 operations/ws	100 operations/ws

** lo – loading operations, ** ws – work shift.*
Source: author

After reconstruction, the total paved area of the CTT increased by almost 170% when the storage area increased by almost 120%. The performance of the handling equipment increased by 50%. Before reconstruction, the handling equipment used only 42.5% of their capacity. After reconstruction, the use of their capacity increased to 83%. The total performance of the CTT increased by 194% (to almost three times of the original performance). The largest share in the increase in overall performance of the CTT is credited to the changing the handling equipment for more efficient ones and changing the internal layout of the CTT and the expansion of the internal road network.

5. Conclusions

The analysis shows that the performance of the CTT is influenced equally by the technical infrastructure of the CTT and by its internal technology. Further rationalization of technology of work (especially in the context of cooperation with road transport and relation to ongoing road transport) could further increase its performance. On the other hand, increasing the number of handling devices would not increase the overall performance of the

CTT without changing the internal terminal technology. Rather, it would decrease the performance because three working handling devices could create collision points in the CTT.

Increasing the operational efficiency can be divided into two planning stages. The first stage should focus on optimal hardware of CTT, which implies a handling equipment (type and number), reloading tracks (with a normative length of 750 m and requisite number), sufficient storage and reloading areas and the proper allocation of these elements. The second stage should focus on optimizing the technology activities of CTT. To optimize technological activities, several mathematical optimization methods can be used. Among these methods, the Critical Path Method (CPM) can be included. It defines the critical activities. These activities have the significant impact on service time, and thus, they directly affect the overall performance of combined transport terminals (Klapita, 2012), (Tadić and Zečević, 2012).

SESSION 7: RAIL TRAFFIC AND TRANSPORT RESEARCH

NEW METHODOLOGY FOR ASSESSING TRANSPORT CONNECTIONS DEPENDING ON THE INTEGRATED TRANSPORT NETWORK

Jozef Gašparík[1], Vladimír Ľupták[2], Pavol Meško[3]
[1,2,3] Department of Railway Transport, Faculty of Operation and Economics of Transport and Communications, University of Zilina, Univerzitná 1, 010 26, Žilina, Slovakia

Abstract: The periodic line transport express an integrated periodic timetable, which is also a periodical liner form of surveillance and network interconnection. An important factor is to reduce the interchange times in selected areas, or transport hubs. The aim is to minimise the total transit time of a passenger from point A to point B. The cornerstone of transport services is to provide travel opportunities by creating links and connections. Often, after the introduction of the new timetable and a discussion of whether it is better or worse, each approach is evaluated in a subjective manner. The authors solved some problems of rail passenger quality services. At present, there is no methodology for assessing train timetables from the transportation point of view as a whole. We evaluate specific trains and connections in the stations only, but not the quality of the connection from point A to point B. The aim of this paper is to introduce a new methodology for the assessment of timetables in terms of passenger traffic, with a focus on connectivity and linking. From the passenger's point of view, it is necessary to assess the availability of travelling opportunities between selected points on the rail network. The travel offer from A to B is in principle affected by travel time, number of transfers (changing the transport means), and number of travel opportunities. Connectivity and linking also affect several factors. This is an outcome in setting the draft criteria for connection evaluation. The introduced study is designed, in purview of the set up, as a tool for an objective evaluation of the quality of public transport service - specifically, the aspects of availability and time services in selected geographical areas in reciprocity to the Standard EN 13816.

Keywords: relation, Lill models, integrated transport network, quality.

1. Dependence of integrated transport network

A transport network is a set of hubs and connecting road sections. On the transport network are moving, entering and then outputting physical objects (e.g. passenger trains, wagon load, etc.). A mathematical model of the network may have a final graph of a finite number of vertices, and a mixed graph with oriented or non-oriented edges, graph G = (V, E, c, d) comprising of a set V of vertices (e.g. train stations, stops, tariff points and so on), a set E of edges (e.g. interstationary sections), c(h) a permeable capacity of the edge or edge part, (h) is the length of the edge.
In transport networks, as in other systems, the distinguishing level is important. The timetables for rail passenger services are sufficient just when one station is in the graph, represented by a single vertex (from network sense, this is called a node). But for the management needs of rail passenger services, each station is designed for the boarding and unboarding of passengers (flow change on the edge) that are seen as a particular peak (Černá and Černý, 2014).
An extension of a conventional line, periodic transport is an integrated periodic timetable (IPTT). In this system are except of periodical repeating of the linear form also monitored the network interconnection and minimising of interchanges times in selected points (transport hubs) where are crossing the individual lines operated for a given period. The aim of this network effect is to minimise the total transferring time of the passenger from point A to point B. This is the most difficult form of operation for transport services, because it demands precision planning and has requirements in terms of boundary conditions. The essential requirements are imposed on the size of the edge periodic time between two nodes, where mutual changes are expected. Substituting the time of the edge can be implemented by a combination of measures related to the infrastructure, setting of the corresponding vehicles, and finally, the connections offered (timetable).
The basis of IPTT consists of the periodic timetable of the superior railway network. Optimal transfer options are given, when all trains meet at the same time at a transfer node (usually it is a transfer train station). In this time period, it is necessary to operate the transfer point by additional means of transport. Thus it is possible, with minimum cost, to transport the passengers from all areas to the transfer stations. In an analogous treatment are passenger transported in the opposite direction in a relatively short time. This creates a scheme of connections in the transfer node, the so-called 'transfer spider'.
Any such transfer spider has a timeline that represents the period of time for the transfer in the node. This timeline determines the edge time. The situation depicted in transfer spiders is regularly repeated after every time period.
The connections meet from opposite directions on the line (for trains crossing) because of timetable symmetry at intervals equal to half the time period. Thus, if the transfer node is situated in the time span of an integer multiple of half of the period, the meeting of lines from the opposite direction is just in these nodes.
The time interval between the symmetrical axes of transfer spiders of two adjacent transfer nodes is called edge time. For periods of one hour, the edge times are 30, 60, 90 minutes. In the systematised transport network described above, one point to any other point can be done without any major time loss from waiting for connections. This possibility should be given for round-trips back to the starting point, so that the axis of symmetry ends in the transfer spider. Therefore, the time required for the round-trip is equal to an integral multiple of the period. These laws shows that the

[2] Corresponding author: vladimir.luptak@fpedas.uniza.sk

timetable conditions of this kind require contingent journey times between nodes, there is no need to prefer the maximum line speed, because all depends on a system travel time.
Using this systemised periodic timetable, rail transport becomes the integrative core of an integrated systematic timetable. By applying the above, the quality of the connection to the transport network is increased, not only at the level of rail transport, but also at the level of integrated transport systems (Drdla, 2014).

2. Continuity of traffic flow between the peaks of the transport network

With the continuity of the traffic flow, it is necessary to choose two places with the coordinates x_1 and x_2 on the route of the transport flow. The size of the flowing masses (e.g. number of trains), located at time t, respectively, $t + \Delta t$, between these points is:

$$\int_{x_1}^{x_2} h(x,t)dx\,, resp. \int_{x_1}^{x_2} h(x,t+\Delta t)dx \tag{1}$$

and thus, their difference, indicating a change of this size is:

$$D = \int_{x_1}^{x_2} (h(x,t+\ \Delta t) - h(x,t)dx \tag{2}$$

This difference of D can be expressed in other ways, such as the difference between during the interval ($t,\ t + \Delta t$) flowing through point x_1 and x_2, and flowing off through point x_2:

$$D = \int_{t}^{t+\Delta t} q(x_1,\tau)d\tau - \int_{t}^{t+\Delta t} q(x_2,\tau)d\tau = \int_{t}^{t+\Delta t} [q(x_1,\tau)d\tau - q(x_2,\tau)]d\tau \tag{3}$$

From the merit of definite integrals results that at each fixed τ, respectively, x is equally:

$$q(x_1,\tau) - q(x_2,\tau) = -\int_{x_1}^{x_2} \left[\frac{\partial q(x_1,\tau)}{\partial x}\right] dx, \qquad h(x,t+\Delta t) - h(x,t) = \int_{t}^{t+\Delta t} \left(\frac{\partial h(x,\tau)}{d\tau}\right) d\tau \tag{4}$$

and thus the difference D can be expressed by a double integral, changing the order of integration:

$$D = \int_{x_1}^{x_2} \left[\int_{t}^{t+\Delta t} \left(\frac{\partial h(x,\tau)}{d\tau}\right) d\tau\right] dx = \int_{t}^{t+\Delta t} \left[-\int_{x_1}^{x_2} \left(\frac{\partial q(x,t)}{\partial x}\right) dx\right] d\tau = \int_{x_1}^{x_2} \left[\int_{t}^{t+\Delta t} \left(-\frac{\partial q(x,\tau)}{dx}\right) d\tau\right] dx \tag{5}$$

Because the first and third integrals have the same limits, and those limits were chosen arbitrarily, also from the integrals equality results integrated functions, and therefore, at any point x and any time τ must be true:

$$\frac{\partial h(x,\tau)}{d\tau} = -\frac{\partial q(x,\tau)}{dx} \Leftrightarrow \frac{\partial h(x,\tau)}{d\tau} + \frac{\partial q(x,\tau)}{dx} = 0 \tag{6}$$

This is one of the most important relationships in traffic flow theory. We call it the continuity equation of traffic flow. In accordance with the physical analogy as well transport flow conditions for the rail transportation conditions, the basic state quantities are characterised, which are necessary for the quality evaluation of connections in the transport network. Generally, there is a need to interpret them for the indicators of relevant quality values. Generally, the state quantities are:

- speed
- intensity = number of units of flow, passing a given point per unit of time
- density = number of flow units per unit distance routes in a given place and a given time
- wave speed = speed of point movement with a given density (Černá and Černý, 2014)

3. Defining quality indicators for the links evaluation on the transport network

The proposed methodology aims to comprehensively cover the possibility of achieving any pair of tariff points by passenger trains on a selected rail network in order to assess the quality of the travel opportunities in the area using selected indicators.

The methodology is based on the evaluation of defined criteria for connectivity between the selected tariff points on the network. Based on the methodology, we evaluate a particular connection. It is necessary to determine whether the connection is evaluated during the workday or the weekend. It is also possible to evaluate a selected workday, Saturday, or Sunday. Consequently, we evaluate the summarising indicators for services in terms of particular relations within the examined networks (Poliak, Križanová, Semanová, and Gajanová, 2014).

For assessing the connectivity and quality of connections in an examined relation (session), we identify the following factors, some of which are introduced in literature (Majerčák et al. 2015):

- Number of connections N_s during the reporting day, direct connections as well connections with changes (transfers).
- Average waiting time of passenger W_i. This is the time that the passenger has to wait for a connection to a point of departure, or possibly a transfer point. It is defined as half of the time between the departure of two successive connections.
- Distance route of relation L_i. This is the travel distance by vehicles creating the connection. This criterion is important to calculate transportation speed and the rate of achievement.
- Type and number of trains creating the connection. This factor reflects the quality of transport services on the connection.
- Transportation time T_p. Time between the departure from the boarding station on the route and disembarking the train at the destination railway station (tariff point).
- Number of transfers (changing means of transport) N_p. This is the absolute number of changes of transport vehicles (trains) before reaching the target station.
- Transfer time T_w. This is the total time that passengers spend waiting for connections at the transfer station (by changing means of transport) when using a particular connection.
- Achieving time T_D. This is the time from embarking when the travel trip begins, to the arrival of the train at the destination railway station. It is calculated as the sum of the average waiting time and transportation time.
- Transportation speed V_P. This is given as a proportion of the distance travelled and time of transfer.
- Achieving start-stop speed V_D. This is given as a proportion of the length of the relation and achieving time.

Transportation speed and achieving speed are important evaluation criteria for the quality of a particular connection relation. They are convenient indicators for comparing public transport link connections with individual transport (Gašparík, Široký, Pečený, and Halás, 2014).

After processing the connections, an evaluation of a single session is necessary to evaluate the relation between tariff points on the network. For each session averages of criteria for all connections are calculated: the number of tranfers, transfer time, the speed of transfer rate and speed of achievement (Zitrický, Gašparík, and Pečený, 2015).

Table 1

Sample of connection assessment on the X – Y relation (workday)

Connection Number	Station X departure [hh:min]	Station Y arrival [hh:min]	Average waiting time W_i [h]	Connection distance L_i [km]	Transport means	Transport time T_p [h]	Number of transfers N_p	Total changing time T_w [min]	Start-stop achieving time T_D [h]	Travel speed V_P [km.h^{-1}]	Start-stop achieving speed V_D [km.h^{-1}]

3. An adequate number of network connection using the Lill model

In transport planning, it is possible to encounter situations where it is necessary to determine quantified estimates of the size of traffic flows between two points over a selected period of time (intensity, density), for situations where it is not possible to carry out a direct survey of transport demand. It is also necessary, in some cases, to determine the impact of individual measures of the transport department of the size of its traffic share. This applies particularly to the number of changes in transport, the number of connections or transport distances.
For these reasons, empirical models are used for determining of the passenger flow characteristics (Lill's model), which is closely related to the number of available network connection.

3.1. Lill's model

Lill's model is used to determine the approximate number of connections between two settlement units, where the distance is generally considered between centres. Lill's model has the following form (Drdla, 2014):

$$j_{1,2} = \frac{A_1 \cdot A_2}{d^n} \cdot K \tag{7}$$

where:
$j_{1,2}$ number of trips between the two cities for a specified time period
$A_{1,2}$ population (in thousands) at specific locations
d distance places
K index (is depending on the largeness and binding of locations 1 and 2),
N value approaching the value of 2.

3.2. The calculation of the optimal number of connections for the selected sessions

In practice, however, using the gravity model is usually not easy and cannot be applied entirely to all relations. This is also evident from the complex determination of the index K, which usually has a value of about 150, but in the case of two cities with a high population density and a short distance between them, this index can be significantly reduced (Stopka, Šimková, and Konečný, 2015).
For the application of the model, selecting the appropriate conurbation is needed, which will be analysed in detail in a case study using Lill's gravity model. We introduce an example calculation for the conurbation Leopoldov–Trnava (in Slovakia):

$$j_{1,2} = \frac{A_1 \cdot A_2}{d^n} \cdot K = \frac{4{,}143 \cdot 64{,}439}{17^2} \cdot 150 = 138.5\ link/24\ hours \tag{8}$$

The calculated values represent the optimal number of total connections of public passenger transport in both directions (Ľupták, Gáborová, and Zitrický, 2015).

4. Conclusion

The proposed methodology is used for the possibility of achieving any pair of tariff points in a selected railway network comprehensively. It not only offers an evaluation of the connectivity of a particular relation, but also objectively assesses the availability of connections between two selected tariff points, based on quality indicators such as average number of transfers, average waiting time, average transportation speed, and average achieving speed. This enables us to evaluate the quality of the travel opportunities in this area by using selected indicators. Subsequently, using Multiple criteria analysis allows us to evaluate the degree of customer satisfaction with selected quality attributes based on their importance. Ultimately, it is possible to examine the statistical dependence of the number of transported rail passengers by examining the quality connection of the network.
The proposal will contribute to the creation of a competitive transport system that efficiently uses system resources. Such is the plan of a Single European Transport Area within the purview of the white paper, 'Roadmap to a Single European Transport Area—Towards a competitive and resource efficient transport system'. This aims for the attainment of an efficient and integrated system of mobility. The importance of the quality, accessibility, and reliability of transport services in the coming years may be even more important.
Another aim of the article is to outline the methodology for determining the required number of transport links between settlement units in passenger traffic. In terms of passengers, it must assess the availability of opportunities to travel between selected points on the transport network. Offering transportation from point A to point B in principle affects transportation time, the number of connections and the number of travel opportunities. On connections and the transfer, connections are thus influenced by a number of factors in transport planning, which is the basis for the empirical model.

ASSESSMENT OF THE SUSTAINABILITY OF TRADITIONAL AND INNOVATIVE RAIL TRACK SYSTEMS IN A LONG-TERM PERSPECTIVE

Marinella Giunta[1]
[1] DICEAM – University Mediterranea of Reggio Calabria, Reggio Calabria, Italy

Abstract: In the last decades special attention is being paid to ballast-less track systems, for their more suitability to be applied in high-speed lines with respect to the ballasted systems. Considering this fact, the present study aims at evaluating the technical, economic and environmental features of competing track solutions in a long-term perspective in order to ascertain their sustainability. Traditional track, who main components are: ballast, sleepers, fastenings, baseplates, rails; and innovative track, usually constituted by pre-stressed concrete slab, fastenings, pad and rails, are put in comparison. Regarding the technical aspects, the advantages and disadvantages of each solution are analyzed, considering the traffic and the speed of the railway line. For the economic aspects, the costs of construction, maintenance and renewal are considered. The environmental aspects account for the impacts produced by the construction/maintenance/renewal activities, and they are estimated in terms of greenhouse emissions (CO_2e) and related cost. A LCCA-based method for assessing the best strategy for the design and management of a railway track over time (maintenance and renewal), considering a long-term perspective, is also set up. Results shows that solutions reasonably priced in the short period could become less sustainable in a long period.

Keywords: ballasted track, slab track, sustainability, LCCA.

1. Introduction

Emerging issues in railway track design and maintenance are related to the worldwide trend towards the increase of axle loads and train speed. Loads and speed induce on the tracks a wide range of bearing and bending stresses in the rails, fasteners, sleepers/slabs, ballast and subgrade due to: i) the static mass of the vehicles; ii) the dynamic actions, such as lateral centrifugal forces on curves, longitudinal acceleration and braking forces; iii) vertical inertial forces from the motion of the wheel-set and its suspension; iv) the vibrational forces induced from imperfections in the rail surface (corrugations, joints, welds, defects) and in the wheels (flats and shells); v) the dynamic response of the track components to the above actions (Tzanakakis, 2013). The need to make the track suitable to withstand these stresses requires an accurate design and includes enhanced maintenance concepts and new or improved construction methods (Esveld, 1999; Esveld, 2001; Gautier, 2015). To this purpose, in recent years special attention is being paid to ballast-less track systems for their more suitability, with respect to the ballasted systems, to be applied in high-speed lines or in lines in which the passenger trains share the track with the freight trains. Ballast-less track slab is a continuous slab of concrete in which the rails are usually supported directly on the upper surface by using resilient pad.

Low maintenance costs (approximately 20-30% less), higher availability, increased service life (50 – 60 years), higher lateral stability, reduction of weight and height of the track, and easier and more economic vegetation control are the main strength points of slab track with respect to the ballasted track, while the weaknesses are: higher construction cost and higher noise radiation due to the lack of noise absorption of the ballast bed (Bilow& Randich, 2000; Esveld, 2001; Darr & Fiebig, 2006; Lichtberger, 2005). Concrete slab track and rail pads dampen some noise frequencies but may reflect other frequencies and this should be addressed in the design and maintenance of slab track (Di Mino, et al. 2009). The mitigation of noise and vibration further increases the costs of the slab track construction significantly.

In the light of the advantages and disadvantages of the competing track solutions the choice of the more effective system, considering the level of traffic in the line, the maximum speed allowed and other boundary conditions, can be supported by an accurate and comprehensive Life Cycle Cost (LCC) analysis, because of the long-lasting impacts related to design choices. According to ISO 15686-5, LCC can be defined as “the cost of an asset or its parte throughout its life cycle, while fulfilling the performance requirements”.

Since the early stage of inception of track design, it is important to take into account the various phases of the life cycle (construction, operation, maintenance, and disposal). In fact, it is very difficult to modify the initial track design, while, on the other side, the performance of the infrastructure depends largely on maintenance and renewal strategies. The track design phase needs to carefully consider all costs during the life span, such as agency costs, user costs, externality costs together with the required performances such as Reliability, Availability, Maintainability, and Safety (RAMS) at system and component level. In this way it is possible to properly evaluate the sustainability of different solutions and recognize the most convenient. After construction and installation, LCCA and RAMS assessment can provide a useful aid for making effective maintenance and operational decisions.

In the present paper a LCCA-based model able to evaluate the total cost of competing track solutions is proposed. By means this model, the traditional track, who main components are ballast, sleepers, fastenings, baseplates, rails; and the innovative track, usually constituted by pre-stressed concrete slab, fastenings, pad and rails, are put in comparison. The technical features of each solution, considering the traffic and the speed of the railway line, the economic aspects, such as the costs of construction, maintenance and renewal and the environmental impacts produced by the construction/maintenance/renewal activities, estimated in terms of greenhouse emissions (CO_2e) and related cost are considered in the assessment.

[1] Corresponding author: marinella.giunta@unirc.it

The model aims at evaluating the best strategy for the design and management of a railway track over the time (maintenance and renewal), considering a long-term perspective and tangible and intangible costs.

2. Methodology for LCC analysis

The railways, as any other transport infrastructures, require relevant resources to guarantee their efficiency and functionality along the time. In Europe, the construction cost of track ranges from 0.4 to 0.6 million of euros/km for single track, while the maintenance costs can vary from 30.000 to 100.000 €/km per year [Baumgartner, 2001; Jimenez-Redondo et al. 2012]. The railway owners generally support these costs. Other important costs, not directly sustained by the owners but affecting the community, relate with the environmental impacts connected to construction, operation and maintenance/renewal of the track. Few data are available regarding the environmental costs even if the environmental concerns have an increasing importance in design and maintenance decision-making process [Milford and Allwood, 2010; Lee, 2008]. All the mentioned costs should be taken into account in decision-making process (new construction projects or maintenance strategies for existing assets) in order to address the properly choices.
In this context, the Life-Cycle Cost Analysis (LCCA) is an effective technique. In fact, LCCA is an engineering economic analysis tool that enables to quantify the differential costs of alternative investment options for a given project. LCC provides the theoretical concepts needed to balance short-term and long-term costs and performances and allows the economic assessment of competing design alternatives considering all significant costs (Zoeteman, 2001; Stalder, 2001; Esveld, 2001).
A comprehensive life cycle cost analysis requires the consideration of all the costs supported during the track life span (Praticò and Giunta, 2016). These costs can be encompassed in three main categories (see Fig. 1):

- Agency costs due to the construction, maintenance and renewal activities,
- User costs mainly related to the delays produced in the railway service by the maintenance and renewal activities,
- Externality costs associated to the impacts on the environment in terms of climate change (co2e), air quality (sox, nox, co, voc, pm, etc.), noise, water quality, soil quality, biodiversity, land take, quarries, landfills, and visual effects (yin and siriphong, 2006; ian et al., 2009) produced by activities and processes carried out during construction/maintenance/renewal, (i.e. Transportation, quarrying, landfill use, cement/steel/rubber production).

In order to implement the LCCA, two main phases have to consider:

- the Life Cycle Inventory (LCI), which is the data collection portion of LCCA. LCI is the straightforward accounting of everything involved in the "system" of interest. It consists of detailed tracking of all the flows in and out of the system, including raw resources or materials, construction processes, energy, emissions to air (CO2e), unit costs. This kind of analysis can be extremely complex. A correct approach to this phase requires a definition of the scope of the LCC analysis having into account that if the scope is too large the tool may become impractical to use and of limited ability to help in decision-making and consideration of alternatives; if the scope is too small then the results may be skewed by the choice of factors considered such that the output becomes unreliable or partisan,
- the Life Cycle Cost Model (LCCM), which defines all costs quantitatively and by means the appropriate discounting allows determining the total cost pertaining to a given solution.

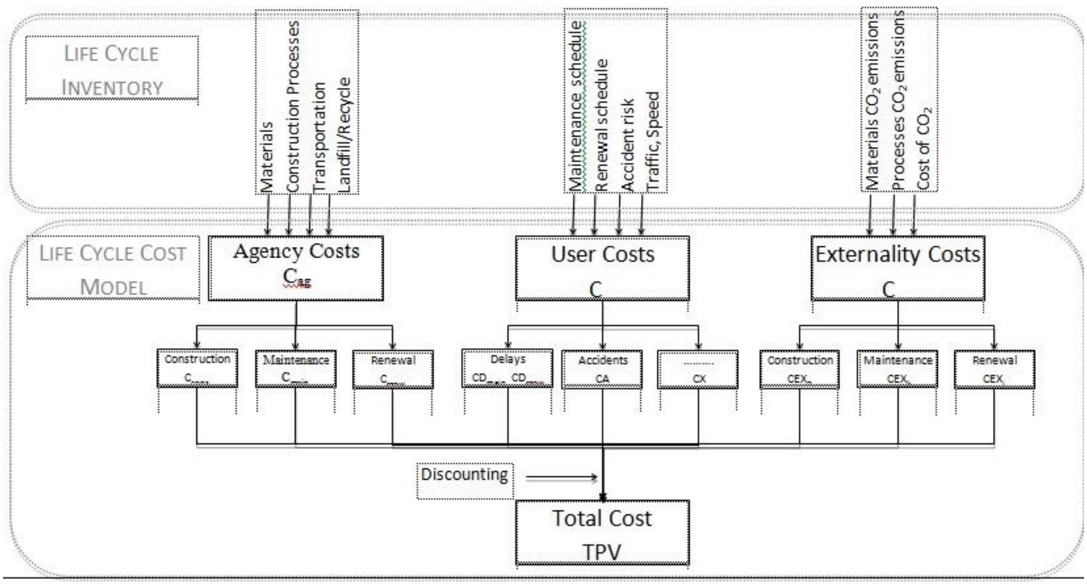

Fig. 1.
Life Cycle Inventory and Life Cycle Cost Modelling

Considering the above discussion, to each track alternative can be associated the total cost (C_{tot}) defined as per equation (1):

$$C_{tot} = C_{ag} + C_{us} + C_{ex} \tag{1}$$

Where; C_{ag} :are the agency costs, C_{us}: the user costs, C_{ex} : the externality costs.
The agency costs refer to the cost of track construction (C_{cons}) and to the costs for maintenance (C_{main}) and renewal (C_{renw}). The agency costs can be split as follows:

$$C_{ag} = C_{cons} + C_{main} + C_{renw} \tag{2}$$

Costs of construction mainly depend on the expense for materials (supply, transportation, etc.) and construction processes; they can be easily estimated based on executed or on going railway projects.
Maintenance encompasses all the minor activities aiming at repairing (corrective maintenance) or preventing (preventive maintenance) rails and sleepers damage, tamping, track stabilization, ballast injection, etc.. Maintenance costs are affected by the traffic (typically the Millions of Gross Tons) and speed: the higher the traffic the higher the maintenance costs and higher speeds correspond to higher maintenance costs (Baumgartner, 2001; Silavong et al., 2014; Thompson, 1986).
Obviously the maintenance strategy adopted by the owner and established since the design stage affect the schedule of the activities (type and time for the interventions) and the related costs.
To the aims of the life cycle cost analysis, the costs for ordinary and extraordinary maintenance can be considered as costs running annually (Baumgartner, 2001). Based on this assumption the annual maintenance costs in this proposed method for LCCA can be estimated by means of the following formulas, set up and calibrated based on the data gathered from Italian projects and international literature (Praticò and Giunta, 2016; Praticò and Giunta 2016a):

$$C_{main} = \left[2.2 \cdot \frac{(V-100)}{200} + 4\right] \cdot GTK^{\left[-0.05 \cdot \frac{(V-100)}{200} + 0.63\right]} \tag{3}$$

Where; C_{main} : refers to the annual maintenance costs (k€, thousands of euros, per single track, per kilometer) V in Km/h is the maximum speed allowed in the line and GTK is traffic expressed by means the indicators gross ton kilometers [ton*km].
Renewal concerns the substitution of the main components of track (ballast, rails, sleepers, slabs, etc…). This activity is linked to the service life of the components and the related costs comprise also the expenditure for disposal and reconstruction.
The user costs are mainly related to the delays originated by restrictions (reduced speed, inoperativeness of railway components, etc.) due to the work zones.
According to Lovett et al., 2015, delays can be divided into two general categories: routine (experienced during normal operations, including crew changes, meets, passes, and civil speed restrictions) and irregular (including maintenance, accidents, and short-term speed restrictions based on track conditions). In the present study, based on owner's standpoint, the irregular delays due to maintenance and renewal of track have been considered and calculated as (Lovett et al., 2015):

$$CD = ((CO + CF)xNL + CW)xTD \tag{4}$$

Where; CD: cost of delay (euro/train-hour), CO: the locomotive operating cost (euro/locomotive-hour), CF: the fuel cost (euro/locomotive-hour), NL: the average number of locomotives, CW: the crew cost (euro/train-hour), TD: the length of delay (hours).
The user costs for delays due to maintenance and renewal are

$$\begin{aligned} C_{us} &= CD_{main} + CD_{renw} = ((CO + CF)xNL + CW)xTD_{main} \\ &+ ((CO + CF)xNL + CW)xTD_{renw} \end{aligned} \tag{5}$$

Where; CD_{main} and CD_{renw} : the costs for delays caused by maintenance and renewal activities respectively, TD_{main} : the average length of delays for maintenance activity, TD_{renw} : the average length of delays for renewal activity.
The externality costs refer to the sum of all costs of environmental impacts produced during the construction and the life cycle of the track (CEX_{kj}). To each j-th impact produced by the k-th process (Q_{kj}), can be associated a unit cost (UP_{kj}). Having in mind the symbols already defined the externality costs can be calculated by means of this equation:

$$C_{ext} = \sum_k \sum_j CEX_{kj} = \sum_k \sum_j Q_{kj} \cdot UP_{kj} \tag{6}$$

The quantification of these costs is a difficult task; in this work the quantity of CO_2 equivalent corresponding to the given process and material has been considered.
As it is well known, carbon dioxide equivalency is a quantity that describes, for a given mixture and amount of greenhouse gas, the amount of CO_2 that would have the same global warming potential (GWP), when measured over a specified timescale (generally, 100 years).
Regarding the cost of a ton of CO_2, it should be noted that it is extremely variable and this variability is a critical factor because of determines a different incidence of externality costs on total cost.
Consequently, in a long-perspective an equilibrium between the sum of agency and user costs (tangible costs) and externality cost (intangible costs) is needed. To this aim a balancing factor (ν) has been defined as the minimum ratio tangible to intangible costs (see equation 10).
In order to make all the discussed and defined costs comparable, they are discounted to a base year considering the interest (r) and inflation (i) rates. The present values (PV) for the quoted costs can be calculated by means of the equations from (7) to (9):

$$PV_{ag} = C_{cons} + \sum C_{main} \cdot \left(\frac{1+i}{1+r}\right)^{Emain} + \sum C_{renw} \cdot \left(\frac{1+i}{1+r}\right)^{Erenw} \tag{7}$$

$$PV_{us} = \sum CD_{main} \cdot \left(\frac{1+i}{1+r}\right)^{Emain} + \sum CD_{renw} \cdot \left(\frac{1+i}{1+r}\right)^{Erenw} \tag{8}$$

$$PV_{ext} = CEX_0 + \sum_k CEX_k \cdot \left(\frac{1+i}{1+r}\right)^{E_k} \tag{9}$$

Where; PV_{ag} : the present value agency costs, PV_{us} : the present value user costs, PV_{ext} : the present value externality costs, i :the inflation rate, r : the interest rate, CEX_0 and CEX_k refer to the externality costs at construction stage and at k-th maintenance/rehabilitation phase respectively, E_{main}: the expected life for maintenance activity, E_{renw} : the expected life for renewal, E_k is the expected life for the k-th activity of maintenance or renewal.
The total present value (TPV) of a given alternative is the sum of the present values of all costs related to them, as already defined. In order to take into account the issue related to the CO_2 cost fluctuation, which affect the externality cost, a balancing factor has been defined as follows:

$$\nu = \min_{j=1,2,..k} \frac{PV_{ag_i} + PV_{uc_i}}{PV_{ext_i}} \tag{10}$$

Where j : the j-th alternative, and k: the number of the alternatives in comparison.
Having in mind this factor, the TPV for a given j-th alternative can be derived from the equation:

$$TPV_j = PV_{ag_j} + PV_{uc_j} + \nu \cdot PV_{extj} \tag{11}$$

3. Application and results

The proposed method for Life Cycle Cost Analysis has been applied to two competing track alternatives: the traditional ballasted track and the ballast-less track. Various types of innovative ballast-less track systems are in service around the world.
The most popular are the Bögl, Shinkansen, Rheda, Sonneville-LVT, Züblin, Stedef and Infundo-Edilon [Esveld, 2001], here the Shinkansen system is considered (Fig. 2). For both the alternatives a double track line 1-km long has been accounted in the application.
Table 1 shows the main characteristics of the components for the two considered track alternatives. For each component an average service life has been also assumed [Milford, et al. 2010].

Table 1
Track components: main characteristics and expected service life

Component	Service life [Years]
Rail *60 UNI, mass= 60,1 Kg/ml*	28
Sleepers *Pre-stressed mono-block, L= 2.60 m, mass= 325 Kg equipped with baseplate*	40
Fastenings *Elastic type Vossloh W14 AV*	40
Ballast *Crushed stones, 500 mm (aver. depth)*	40
Subballast/Concrete road-bed *Cement treated layer 200 mm depth*	40
Slab *Pre-stressed concrete with cylindrical bollard* *4,93 m x 2,34 m x 0,19 m; mass = 5 tons*	60

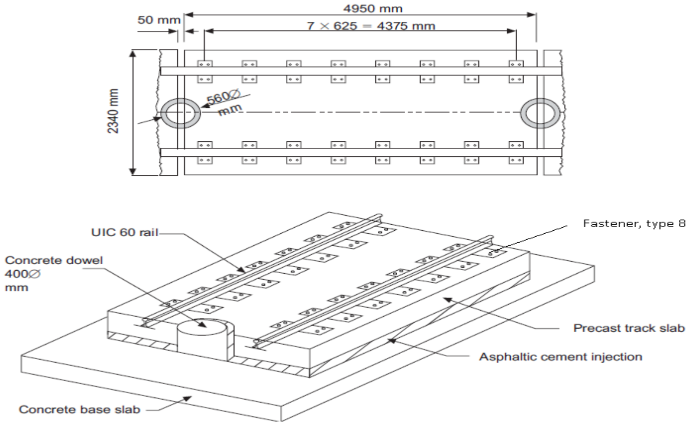

Fig. 2.
Slab track
Source: Esveld 2001

Results of the application are shown in figures 3-5.
Figure 3 represents the trend of TPV for the two alternatives, the ballasted (blue continuous line) and the slab track (red dashed line). As it can be observed, at end of construction (year 0), the total cost of slab track is higher of about 1.5 times than the one of the ballasted track, this finding complies with the existing international literature [Schilder and Diederich, 2007; Pichler and Fenske, 2013; Gautier, 2015]. Note that in this case the total cost encompasses both construction and externality costs. After about 26 years a breakeven of the total present values of the two solutions can be observed. In the successive years the total present value of slab track remains lower with respect to the one of ballasted. The difference between the two costs is quite small.

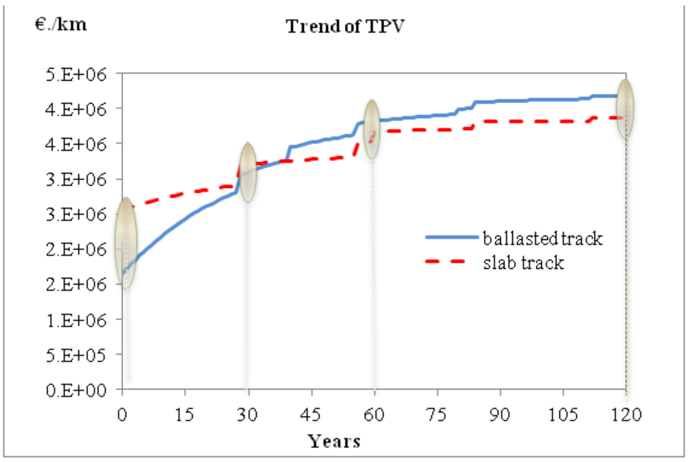

Fig. 3.
Trend of TPV for ballasted and slab track

In order to understand better the sustainability of the two solutions under the different standpoints, costs of construction and management, user costs and environmental costs, the following figures 4 and 5 provide a breakdown of these costs in different time frame of track life: 0, 30, 60, and 120 years.

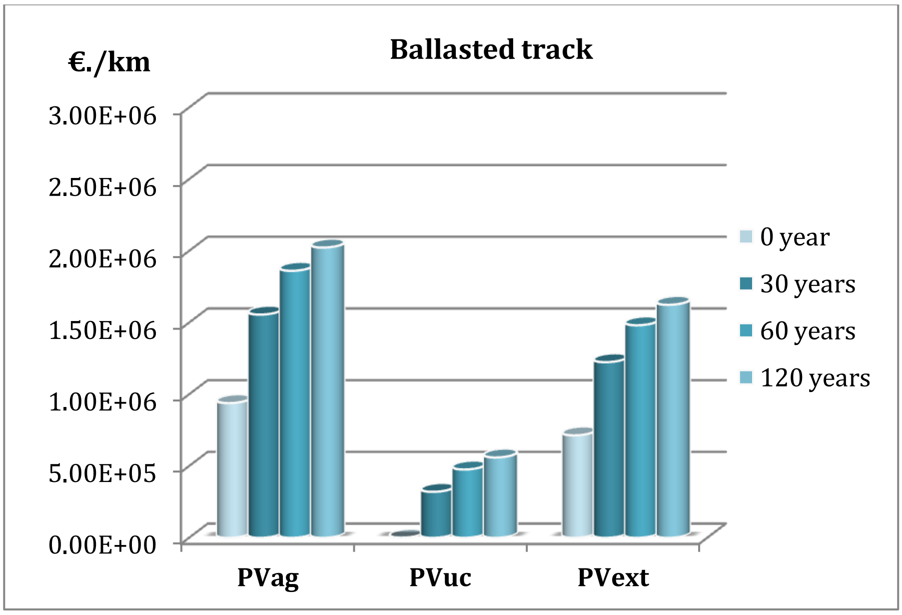

Fig. 4.
Trend of agency, user and externality costs for ballasted track in the time frame 0, 30, 60 120 years

With regard to the agency costs, despite the lower construction cost of the traditional ballasted track (if compared to the slab track), the more maintenance exigencies during the life cycle make this solution quite expensive in the long term. For this aspect, the slab solution exhibits an opposite trend namely higher construction cost and lower maintenance and renewal costs.

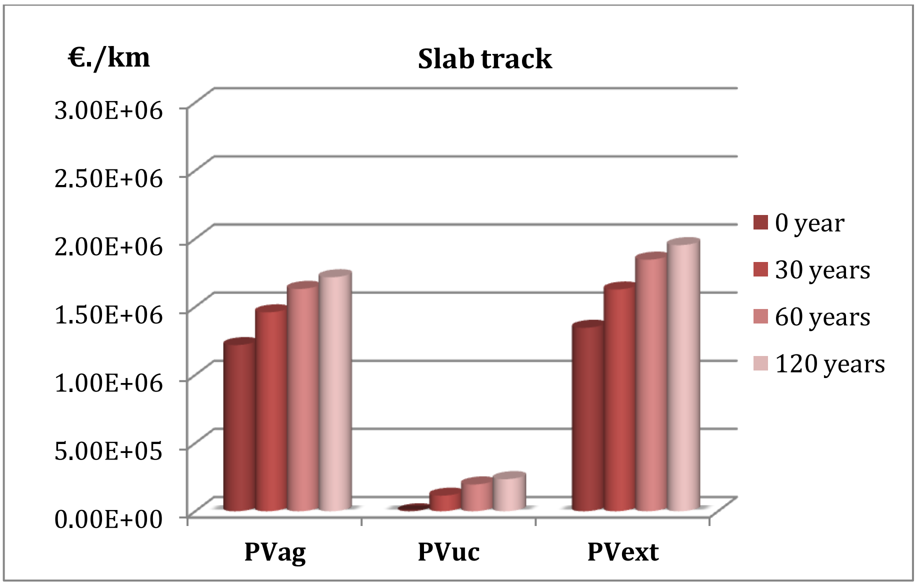

Fig. 5.
Trend of agency, user and externality costs for slab track in the time frame 0, 30, 60 120 years

The user costs, follow the same trend of the agency costs; their value is, in fact, affected by the maintenance and renewal activities connected to the two solutions, because of the delays produced for passengers and freight moving in the railway line. For this reason, the lower maintenance exigencies and the higher service life of the slab track make this solution more favourable than the ballasted track.
From the environmental standpoint, the slab track appears less preferable than the traditional ballasted track. This is mainly due to the carbon footprint associated whit the cement and concrete production. The embedded carbon factor of

a slab track is 0.3-0.4 Kg CO_2/Kg while for ballast and the sleepers is respectively 0.005 Kg CO_2/Kg and 0.27-0.28 Kg CO_2/Kg (Milford, 2010, Praticò et. al 2013).

3. Discussion and conclusion

Results of the LCCA analysis carried out on the two track systems ballasted and ballast-less, following the method set up, confirms that a comprehensive evaluation of different track options needs the consideration of agency, user and externality costs. In fact, tangible and intangible costs govern the suitability of a track to fit transportation and environmental demand. Considering and integrating technical issues and environmental concerns may be a difficult task, but it results the best way to make a complete comparison among different design and maintenance track solutions. Based on the findings of this study the following conclusions can be drawn.

As obvious, the total cost for the two track solutions, increases over time while the growth rate decreases. The two solutions even if at construction stage exhibit a significant different value (higher for slab track), after less than 30 years reach a breakeven and invert the trend. Based on the total cost, the evaluation of the two solutions is different depending on whether it refers to the short or long term.

The break-down of the costs allows highlighting some significant conclusions.

The agency costs (construction, maintenance and renewal), lower at construction stage and in the short period for the ballasted track with respect to the slab track, in a long term perspective, for the first solution yield a value which is 1.15 times higher than the one of the slab track.

The user costs for ballasted track, lower in the short period, become, in the long term perspective, 2.3 times higher than the ones exhibited by the slab track.

The environmental costs show an opposite tendency for the two solutions. In more detail, the carbon footprint is a key factor in the comparison. The CO_2 emission for cement/concrete is very high if compared with the ballast. Consequently for the slab solution the externality costs are 1.2 times higher than the traditional track.

In the light of the above consideration, in a long-term and general perspective, the ballast-less track solution results preferable with respect to the traditional ballasted track.

The above results can benefit both researchers and practitioners.

Abstract: Simulation modelling is today widely used and acknowledged as a very efficient and reliable technique for analyzing train movements. During the simulation predefined trains run on a railway network according to the timetable and under the constraints of the signaling system. Specialized software tool (OpenTrack), used to prepare, organize, run simulations and manage the outputs, can analyze and display the resulting data in the form of diagrams, train graphs, occupation diagrams and statistics. In this paper, simulation model, created in OpenTrack simulation tool, was used to measure train delays and unscheduled stops on a passing sidings of a single track railway line caused by train conflicts. Conclusions generated from this analysis could be used in strategic planning for determining infrastructure improvements of passing sidings on single track lines, but also in tactical planning for introducing timetable improvements regarding necessary station intervals and buffer times. Simulation model was generated and tested on a Serbian railways single track railway line between stations Stalać and Đunis.

Keywords: railway simulation, OpenTrack, passing siding, single track lines.

1. Introduction

Analysis of the train traffic is very important as an input to a process of planning in railways. Railway simulation is used to generate data on capacity of lines, train delays, train stops, energy consumption etc (Hansen and Pachl, 2014; Čičak, 2003). In last two decades many authors have used various simulation techniques, methods, programming languages or specialized software's to model railway traffic (Barber et al., 2007; Milinković et al., 2013; Jeremić et al., 2016; Milinković et al., 2015). One of the most commonly used tools for simulation of train traffic is OpenTrack. It is an object-oriented user-friendly tool for modeling in railways, develop to answer questions about railway operations by simulation (Nash and Huerlimann, 2004; Haramina et al., 2016). After a simulation run, OpenTrack can analyze and display the resulting data in the form of diagrams, train graphs, occupation diagrams and statistics. Due to the fact that the models can be easily created, and linked to the input and output sources, the OpenTrack software can be very important tool in the process of strategical, tactical, or operational planning (Milosavljević et al., 2014; Fischer et al., 2012).

We have created a simulation model of a railway traffic on a section of railway line Beograd – Niš – Preševo from Stalać to Đunis. The simulation model is used to evaluate the effects of the change in track layout when introducing various types of passing sidings on the existing infrastructure. Three different infrastructure layout solutions for passing sidings were analyzed. We have created the simulation model in OpenTrack simulation tool, and used it to measure train delays and unscheduled stops on a passing sidings of a single track railway line caused by train conflicts.

2. OpenTrack simulation software

OpenTrack was developed at the Swiss Federal Institute of Technology's Institute for Transportation Planning and Systems (ETH IVT). Figure 1 illustrates the three main elements of OpenTrack: data input, simulation, and output.

OpenTrack is a microscopic synchronous railroad simulation model. As such it simulates the behavior of all railway elements (infrastructure network, rolling stock, and timetable), as well as all the processes between them. It can be easily used for many different types of projects, including testing the stability of a new timetable, evaluating the benefits of different long-term infrastructure improvement programs, and analyzing the impacts of different rolling stock.

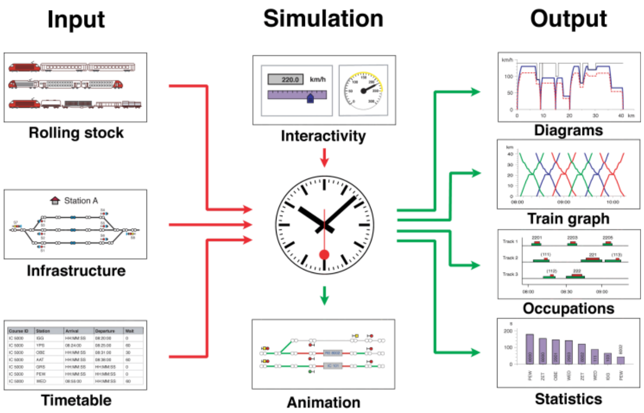

Fig. 1.
Data flow in simulation of railway operation

2.1. Input Data

OpenTrack manages input data in three modules: rolling stock (trains), infrastructure, and timetable. Users enter input information into these modules and OpenTrack stores it in a database structure. Once data has been entered into the program, it can be used in many different simulation projects. Similarly, different segments of the infrastructure network can be entered separately into the database and then used individually to model operations on the particular segment or together to model larger networks. Train data (locomotive and wagons) is entered into the OpenTrack database with easy to use forms displayed using pull down menus. Infrastructure data (e.g. track layout, signal type/location) is entered with a user-friendly graphical interface; quantitative infrastructure data (e.g. elevation) is added using input forms linked to the graphical elements, and timetable data is entered using forms (including shortcuts that enable data input to be completed efficiently).

2.2. Simulation

In order to run a simulation using OpenTrack the user specifies the trains, infrastructure and timetable to be modeled along with a series of simulation parameters (e.g. animation formats) on a preferences window. During the simulation, OpenTrack attempts to meet the user-defined timetable on the specified infrastructure network based on the train characteristics. OpenTrack uses a mixed continuous/discrete simulation process that allows a time driven running of all the continuous and discrete processes (of both the vehicles and the safety systems) under the conditions of the integrated dispatching rules.
The continuous simulation is dynamic calculation of train movements based on Newton’s motion formulas. For each time step, the maximum force between the locomotive’s wheels and the tracks is calculated and then used to calculate acceleration. Next, the acceleration function is integrated to provide the train’s speed function and is integrated a second time to provide the train’s position function.
The discrete simulation process models operation of the safety systems; in other words, train movements are governed by the track network’s signals. Therefore, parameters including occupied track sections, signal switching times, and restrictive signal states all influence the train performance.
OpenTrack is a dynamic rail simulation program. As such, the simulated operation of trains depends on the state of the system at each step in the process as well as the original user-defined objective data (e.g. desired schedule). A simple way of describing dynamic rail simulation is that the program decides what routes trains use while the program is running. Finally, dynamic simulation enables users to run OpenTrack in a step-by-step process and monitor results at each step. Users can also specify exactly what results are displayed on the screen. Running in a step-by-step mode with real time data presented on screen helps users to identify problems and develop alternative solutions.

2.3. Output

One of the major benefits of using an object-oriented language is the great variety of data types, presentation formats, and specifications that are available to the user. During the OpenTrack simulation each train feeds a virtual tachograph (output database), which stores data such as acceleration, speed, and distance covered. OpenTrack allows users to present output data in many different formats including various forms of graphs (e.g. time-space diagrams), tables, and images. Similarly, users can choose to model the entire network or selected parts, depending on their needs.

3. Simulation model of track section with passing sidings

In order to evaluate different solutions for passing sidings, three models of a section of railway line Beograd – Niš – Preševo from Stalać to Đunis were created. Models represent the passing sidings track layout variants.

3.1. Single track section Stalać – Đunis

Single track section Stalać – Đunis is a part of a mainline Beograd – Niš between km 176+311 and km 194+940. On this section there are two passing sidings, Stevanac and Staro Trubarevo, one station Braljina and one stopping point, Cerovo – Ražanj. Whole section is equipped with automatic block signaling and traffic is controlled from dispatching center Niš. Train speeds on this section are not impressive and their range is from 65 km/h between Stalać and Braljina and 85 km/h between Braljina and Đunis. In reality there are many speed restrictions with maximum speed from 30 km/h to 50 km/h. Passing siding Stevanac is located at km 181+900, it has two tracks, one main track and one siding, length of both tracks is around 700 m. It is situated in a sharp curve near Južna Morava River. Station Braljina is located at km 186+486,5, it has four tracks with approximate length around 650 m. Passing siding Staro Trubarevo is located at km 192+216, it has two tracks, one main and one siding which are around 712 m long. All stations are equipped with relay interlocking devices and are controlled remotely from dispatching center Niš. None of these stations are equipped for simultaneous entrances of two trains arriving from opposing direction.

3.2. Model of up-to-date track layout

Model of existing infrastructure was created using current data with some approximations (Figure 2). Some dead end tracks were not included in the model, and train speeds were used from current timetable. Sections with restricted speed were not included in the simulations, although some of them exist for a number of years.

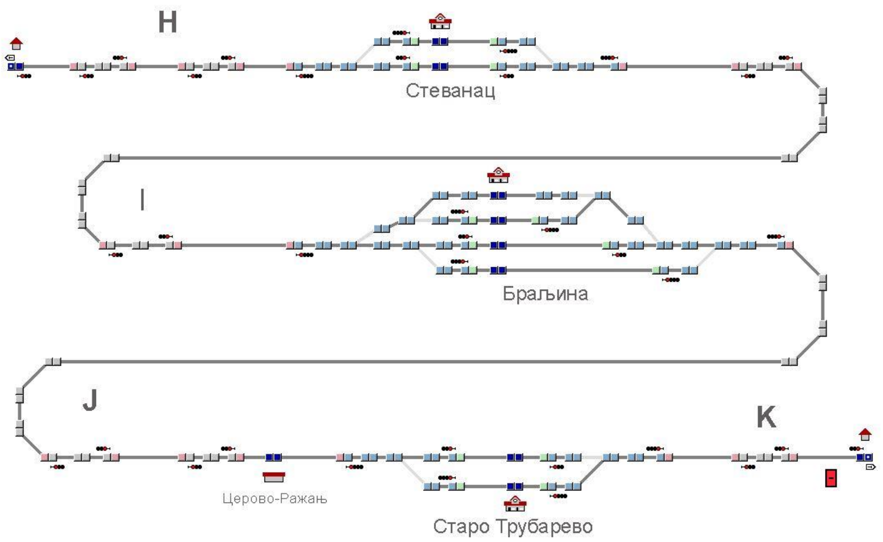

Fig. 2.
Model of current infrastructure

For this model, 2015/2016 timetable was used, but, since timetable for this line has a low number of trains, we have added 8 more passenger and 60 more freight trains, so that model could be tested in more difficult conditions.

3.3. Model with modified passing sidings

In model with modified passing sidings two modifications were performed on passing sidings infrastructure. First modification was performed in Stevanac with (track) block signals placed in front of exit signals and second was performed in Staro Trubarevo with dead end track on each end of the station. Those two solutions were compared with current infrastructure solution, but also compared to each other. Main goal of each modification was to enable simultaneous entrances of two trains from opposing direction, but at the same time their track length should be sufficient to accommodate longest train allowed on this line.

In passing siding Stevanac modifications were performed by placing block signals 50 m in front of each exit signal. This modification enables simultaneous entrances of two trains when route from each direction is set only to block signal. When route is set to exit signal, route overlap leads over entrance switch and forbids entrance of a train from other side. Same modifications were performed on station Braljina, block signal were placed 50 m in front of each exit signal on track two, three and four. On other hand, these modifications shortened useful length of tracks in both stations for 100 meters, although they are still longer than required for longest train on this section. Modifications on passing siding Staro Trubarevo were more extensive and, instead of block signals, four short dead end tracks were built. That operation required installment of four new switches, and consequently shortening both track for approximately 107 meters.

When comparing solutions applied in passing sidings Stevanac and Staro Trubarevo, it can be seen that infrastructure solution applied in Stevanac is more favorable in terms of useful track length and required investment costs and solution for Staro Trubarevo is more favorable in terms of safety. Useful length of track in Stevanac after modification is longer than in Staro Trubarevo for approximately 50 m, but also investments in four block signals are much lower than investments in four new switches and approximately 200 m of dead end tracks. Model with modified passing siding is shown in Figure 3.

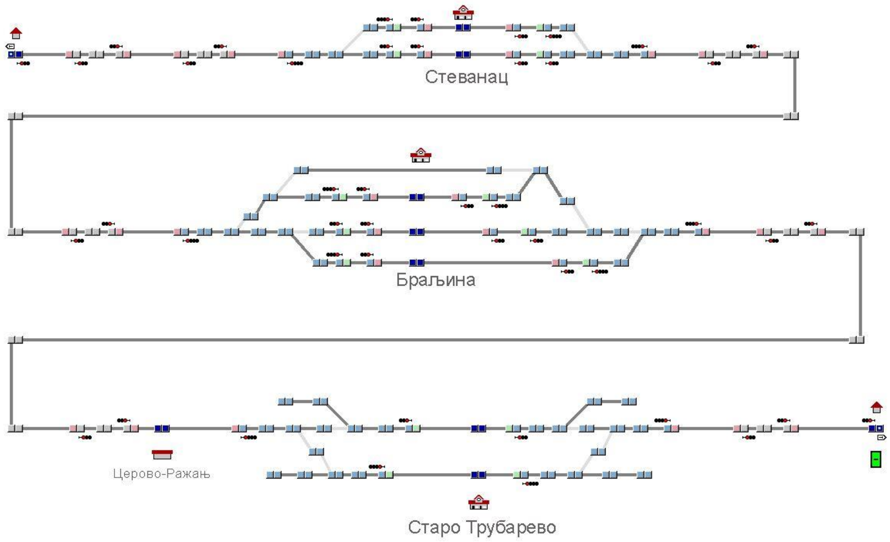

Fig. 3.
Model with modified passing sidings

3.4. Model with long passing sidings

In model with long passing sidings, sidings Stevanac and Staro Trubarevo were modified in a way that their track length was doubled. Goal was to create a siding which was long as two shortest 1000 m block sections. In order to minimize investment costs, sidings were extended on only one side, so only one switch was required to move. Criterion for siding extension was to extend it in the direction of longer track section between stations. Two variants of long passing sidings were created, one with crossovers in the middle and another without crossovers. For passing siding Stevanac second variant without crossovers was chosen. Reasons lay in fact that passing siding Stevanac is located on difficult terrain and in sharp curve, which would create difficulties in building and maintaining crossovers. Since track section between Stalać and Stevanac is longer than track section between Stevanac and Braljina, siding was extended in the direction of Stalać. Another problem was tunnel “Stevanac” located between switch number one and entrance signal. Since new crossovers would be located in the middle of the tunnel, solution without crossovers was chosen. Passing siding Staro Trubarevo is located in less difficult terrain so solution with double crossovers was chosen. Since track section between Braljina and Staro Trubarevo is longer than section between Staro Trubarevo and Đunis, siding was extended towards Braljina.

Another consequence of siding extension was reduction of both number and lengths of block sections between stations. Main criteria for shortening block sections were that block section length of first and last block section would not be shortened since they already have shortest allowable length and that minimum block section length for other sections should be 950 m. Between Stalać and Stevanac number of block was not reduced but length of second block section from Stalać was shortened. Between Stevanac and Braljina block lengths and number of block sections remained the same. Between Braljina and Staro Trubarevo shortening of existing block sections led to insufficient block lengths, therefore one block section needed to be removed. Remaining two block sections evenly divided track section between these two stations. Between Staro Trubarevo and Đunis block sections remained the same, both in number and lengths. Model with long passing sidings is shown in Figure 4.

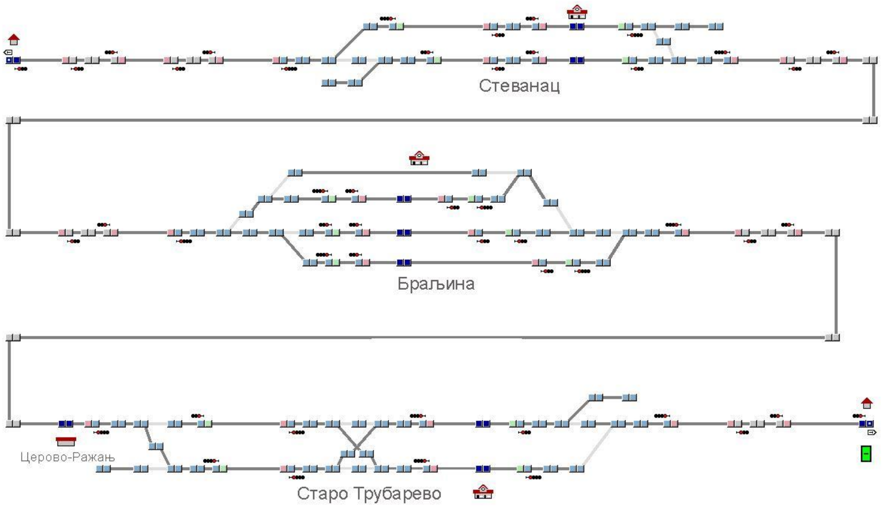

Fig. 4.
Model with long passing sidings

4. Simulation model results

There are number of output files which OpenTrack generates during simulations (Figure 5). Some files contain global information about whole simulation while others contain information about particular train or track section. In this case, purpose of these models was to determine impact of different infrastructure solutions of passing sidings on traffic flow. For this comparison three criteria were used: number of stops in front of entrance signal, number of speed reductions caused by red light on entrance signal and number of passes by distant block signal on “caution, expect stop” i.e. yellow light. All information were obtained from file OT_Messages.txt which includes all warnings and messages which appear during simulation. Number of stops in front of entrance signal was chosen as a criterion mainly because main goal of projected infrastructure solutions was to enable simultaneous entrances of opposing trains in siding. Concerning the fact than main reason for stopping trains in front of an entrance signal is lack of possibility for simultaneous entrances, infrastructure solutions which allow simultaneous entrances would at the same time decrease number of stops in front of entrance signal. Since same timetable was used for all three simulation models, by comparing data for the same trains it can be concluded how much number of stops varies from one variant to other. Part of file OT_Messages.txt edited in Excel is shown on Figure 6.

Fig. 6.
Part of OT_Messages.txt file

4.1. Number of stops in front of entrance signals

In regular operating conditions when all trains are running on time, stoppings in front of the entrance signal or passing by distant signal which shows “caution, expect stop” are not planned. If these events occur, they unnecessarily prolong travelling times and decrease traffic flow. Therefore, certain station buffer times are always planned and included in the timetable so that trains would not be stopped or slowed down in front of entrance signal. Since all three models are using the same timetable without delays, stoppings in front of entrance signals should not occur. On the other hand running times which are included in current year timetable used in simulations are not shortest running times since they include large time reserve caused by poor track condition. During simulation, OpenTrack calculates running times by dividing block length with maximum block speed which results in a shorter running times than those included in the timetable. Shorter running times lead to different arrival times in stations which in turn lead to shorter time differences between opposing trains. And in some cases those shorter time differences could lead to stopping of one train if there is no possibility for simultaneous entrances. These conditions actually lead to more realistic operating conditions in which freight trains are rarely following strict schedule. Number of stops in front of entrance signals for each of three variants and all stations are shown in table 1.

Table 1
Number of stops per entrance signal

Station / Passing siding	Entrance signal	Number of stopped trains		
		V1	V2	V3
Stevanac	Hu92	8	1	-
	Iu91	5	3	4
Braljina	Iu92	4	2	5
	Ju91	8	6	6
Staro Trubarevo	Ju92	7	-	9
	Ku91	5	-	-
Total		37	12	24

As it can be seen from Table 1 number of stops at siding Stevanac and station Braljina significantly decreased in second variant with block signals compared with current condition model, and at Staro Trubarevo in second variant there were no stops at all. Reasons lay in fact that in variant two Staro Trubarevo was equipped with dead end tracks, and that route overlap behind exit signals always led to dead end tracks, which enabled simultaneous entrances at all times.
In third variant with long sidings there were also less stops than in first variant with current conditions, but in some cases slightly more than in second variant with modified sidings. Therefore, third variant requires deeper analysis using some other criteria.
Second observed criterion was number of trains which are slowing down in front of entrance signal. Results are shown in table 2.

Table 2
Number of trains which slowed down in front of entrance signal

Station / Passing siding	Entrance signal	Number of stopped trains		
		V1	V2	V3
Stevanac	Hu92	9	9	-
	Iu91	6	3	5
Braljina	Iu92	6	10	8
	Ju91	13	11	16
Staro Trubarevo	Ju92	10	1	16
	Ku91	6	-	-
Total		50	34	45

Results show than number of trains which slow down in front of entrance signal is larger than number of trains which stop in front of same entrance signals. Further analysis confirmed that same trains which stopped in front of entrance signal also slowed down in front of the same signal. That also proved that there are few new trains which slowed down in front of entrance signal, but did not stop. In both passing sidings Stevanac and Staro Trubarevo number of trains slowing down is lower than in first variant. In third variant in some case there were more trains slowing down, even more than in first variant of current condition. Third criterion was number of trains which passed by distant block signal with aspect „caution, expect stop“, which are shown in table 3.

Table 3
Number of trains which passed on „caution, expect stop"

Station / Passing siding	Distant signal	Number of stopped trains		
		V1	V2	V3
Stevanac	H32	13	9	-
	I21	8	3	5
Braljina	I32	13	9	-
	J21	13	11	8
Staro Trubarevo	J32	10	1	16
	K21	6	-	-
Total		63	33	29

Results show than number of trains which passed by distant block signal with aspect „caution, expect stop" is even larger than number of trains which stop in front of corresponding entrance signals. That indicates that there are trains which passed distant signal on yellow, but did not stop at the entrance signal because of signal change to some other aspect different than red. This criterion also favors second variant over first and shows some improvement, while in variant 3 improvement are more pronounced and in some cases there were no trains which passed distant signal on yellow, which is considered optimal operating condition.

5. Conclusion

In comparison with existing track layout variant, model with modified passing sidings showed significant improvement with reduction of stops and delays on entrance signals. Variant with dead end track showed better results than the one with block signals. In comparison with existing track layout model, model with long siding gives shorter and less occurring stops, but not in all cases. Simulation results generated from OpenTrack simulation models provided enough information about effect of different infrastructure solutions of passing sidings. Consequently, it can be concluded that modified passing siding with dead end tracks or block signals provide enough improvement over classical sidings. To form more detailed conclusion on which of these two solutions has more advantages it requires to run more extensive simulation with experimenting with train delays scenarios and for the various timetable inputs. Also, simulation should be just one of the inputs along with safety and economical parameters for the further analysis (multicriteria decision making or optimization approach). Solution with long passing siding also showed improvement over current condition, but not significantly compared to the variant with modified passing sidings. General conclusion can be that the modified and long passing sidings have lots of advantages over classical sidings and they should be considered when single track railway lines are built or reconstructed.
Further research on the effects of passing sidings on train traffic could benefit from this research by applying the same simulation modelling approach. Depending on the goal of the research various simulation scenarios could be generated. For example, simulation could be used in strategic planning for determining infrastructure improvements of passing sidings on single track lines, but also in tactical planning for introducing timetable improvements regarding necessary analysis of train delays, station intervals and buffer times, etc.

IMPROVING THE TRANSPORT CAPACITY OF THE INTERMODAL TRAIN AND TRACK BASED ON DIFFERENT TYPES OF WAGONS

Jaroslav Mašek[1], Juraj Čamaj[2], Ivan Belošević[3]
[1,2] University of Žilina, Faculty of Operation and Economics of Transport and Communication, Univerzitná 8215/1, 010 26 Žilina, Slovakia
[3] University of Belgrade Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, 11 000 Belgrade, Serbia

Abstract: The paper consist of the analysis of selected indicators of transport characteristics of intermodal wagons and compare intermodal wagons in terms of main characteristics. The paper deals with possibilities of increase intermodal train capacity by using the different types of railway wagon. In the first part is created a mathematical model to calculate the capacity of the train. The model is based on the main limiting parameters of the train - maximum number of axles per train, maximum gross weight of train, maximum length of train and mount of transported intermodal loading units. In the second part is the model applied to some different type of trains with different composition of the train set and different average weights of intermodal loading units and a train consisting of the different type of wagons. The result is to identify where the carrying capacity of the original trains are higher, respectively less than a capacity of train consisting of others type of wagons.

Keywords: transport capacity, intermodal transport, intermodal wagons.

1. Introduction

Selection of the appropriate transport means is a key element determining and conditioning factors of providing the quality transport service and satisfaction with the railway operator services. The railway operator may provide quality transportation services - to be flexible, reliable, have suitable prices, etc., however the final quality of the movement of goods from the departure place to the destination will always depend on the choice of the appropriate transport mean - rail wagon. Railway wagons are the most important part of mobile base the rail transport operation and are an essential means of making transport and the providing of transport services. Under the railway rolling stock we mean all railway vehicles, which are used for the safe movement of the persons and goods.
The loading capacity of train is number of wagons, TEUs or the mass of goods that can be transported by one train. This paper works with model of the capacity converted on number of TEUs. The basic assumption is that using special long wagon will increase total capacity per train.
This paper consists of two parts:

- Theoretical model – general characteristics of relationships and formulas;
- Application of the model on selected model trains with use of common wagons for intermodal transport and with use of special long wagons.

2. Indicators of the transport characteristics of cargo rail wagons

Transport characteristics of cargo rail wagons is quantitative and qualitative expression of their ability to safely transport goods from the departure place to the destination and is conditioned mainly by designing every type of wagons as well as their use and composition of the wagon fleet and composition of different types of transported goods. Indicators of the transport characteristics are divided into three groups:

A. base indicators of wagon loading capacity,
B. own parameters of the transport characteristics,
C. comprehensive indicators of using the rolling stock fleet.

A. Base indicators of wagon loading capacity are based on the main technical characteristics of the wagon. These are the indicators of the technical possibilities of the use of the loading capacity of the wagon and also depending on the capacity of other parts of the railway infrastructure, for example railway lines. The base indicators include, in particular loading width, length, height, area and space. Also included loading capacity wagon, load per axle, wagon own weight (tare) and the weight per wagon length. Base indicators of wagon loading capacity are usually marked directly on the wagon through internationally standardized signs.

B. Own parameters of the transport characteristics value every elements of wagon ability to transport the goods and show dependencies between these elements that determine the possibility of using different types of wagons in terms of shipments by type and character of the goods. Own indicators of the transport characteristics include:

- the technical coefficient tare,
- the loading coefficient tare,
- the dynamic coefficient of tare.

[1] Corresponding author: Jaroslav.Masek@fpedas.uniza.sk

The technical coefficient tare expresses weight ratio of the own wagon weight (tare) and wagon´s loading weight. This coefficient characterizes the constructional quality of the wagon design. As smaller this value is, the better is constructional quality of the wagon. The technical coefficient tare reaches the relatively high values in case of wagon with special construction equipment.
The loading coefficient tare expresses weight ratio of the own wagon weight (tare) and weight of the actually transported goods. When calculating the load coefficient tare must take into account all types of goods for which the wagon is designed and frequency of transportations. This coefficient is inversely dependent on the loading wagon weight. Loading capacity is the best used in case of wagon with special construction, for the universal wagons is this coefficient is less.
Dynamic coefficient of tare reflects the use of the loading capacity of wagon with respect to the empty wagon´s runs.

C. Comprehensive indicators of using fleet capacity deals with ability of wagon to transport in the conditions of specific configuration of the rolling stock, in condition of all types of goods and the organization and operation of the transport technology. Among the indicators of comprehensive of using rolling stock fleet capacity are:

- the average static using of loaded wagon unit,
- the average dynamic using of the loaded wagon unit,
- the average dynamic using of wagon unit of rolling stock fleet.

Except the previous indicators of the transport characteristics cargo wagon there are others characteristics according to we can be distinguished wagons. Others transport characteristics include:

- the ratio of the maximum loading weight and wagon´s tare,
- the ratio of the loading weight and loading length of the wagon,
- loaded weight ratio and wagon length over buffers,
- unused (dead) loading length of wagon,
- the maximum loading weight per meter of the wagon,
- unused loading capacity for D tracks categories,
- dependence of the maximum loading weight per meter of the wagon and the wagon length over buffers.

3. The possibility of increasing the transport capacity of railway infrastructure

Increasing the capacity of rail infrastructure can be done in several ways, including:

- construction and reconstruction work:
  - to increase the line speed,
  - the construction of double track inserts for flying cruising and overtaking,
  - the double-tracking railway section,
  - the electrification,
- change in the organization of train traffic:
  - in the freight railway transport exists possibility of the implementation of new methods for the development of freight trains (time-discrete forming of trains) reflected in the plan of train formatting,
- increase train capacity:
  - by appropriate choice of the composition of cargo wagons in each train.

This choice of suitable cargo wagons in train set is one of the least expensive way of increasing the capacity of rail infrastructure.

4. Calculation of the maximum number of TEU unit in train

Maximum number of TEUs transported in train depends on the train parameters – length, weight and number of axles normative. The number of TEUs per train is limited by:

- maximum number of axles per train,
- maximum gross weight of train,
- maximum length of train,
- number of TEUs per one wagon.

4.1. Number of axles per train limitation

Maximum number of TEUs depending on normative of axles per train is calculated according to the following relation:
General relationship:

$$N_{TEU}^{max/train} = \frac{N_{axles}^{max/train} - N_{axles}^{Locomotive}}{N_{axles}^{wagon}} . N_{TEU}^{max/wagon} \quad (1)$$

where:
$N_{axles}^{max/train}$ - maximum number of axles per train (axles),
$N_{axles}^{Locomotive}$ - number of locomotive axles (axles),
N_{axlex}^{wagon} - number of axles per wagon (axles),
$N_{TEU}^{max/wagon}$ - maximum number of TEUs on wagon (TEU).

This equation can be edited for common wagon for intermodal transport and for special long wagon. Common wagon for intermodal transport (wagon type Sgnss) can carry maximum 3 TEUs. Special long wagon can carry maximum 4 TEUs.
Formula edited for common 4 – axle wagon (type Sgnss):

$$N_{TEU}^{max/train} = \frac{N_{axle}^{max/train} - N_{axle}^{Locomotive}}{4} . 3 \tag{2}$$

where:
$N_{axle}^{max/train}$- maximum number of axles per train (axles),
$N_{axles}^{Locomotive}$ - number of locomotive axles (axles).

Formula edited for special long wagon:

$$N_{TEU}^{max/train} = \frac{N_{axles}^{max/train} - N_{axles}^{Locomotive}}{4} . 4 = N_{axles}^{max/train} - N_{axles}^{Locomotive} \tag{3}$$

where:
$N_{axle}^{max/train}$– maximum number of axles per train (axles),
$N_{axles}^{Locomotive}$ – number of locomotive axles (axles).

4.2. Maximum train weight limitation

Maximum gross weight of train is depending on the type of locomotive, on the line parameters and the vehicle resistances. It is set in the prescriptions for each line, type of locomotive and used wagons. Maximum number of TEUs per train limited by maximum gross weight of train is calculated by following formulas:

$$N_{TEU}^{max/train} = \frac{M_{train}^{max} - M_{Locomotive}}{M_{wagon}^{tarra} + N_{wagon}^{\emptyset,TEU} . M_{TEU}^{\emptyset}} . N_{wagon}^{\emptyset,TEU} \tag{4}$$

where:
$N_{TEU}^{max/train}$ – maximum number of TEUs in train (TEU),
M_{train}^{max} – maximum gross weight of train (tons),
$M_{Locomotive}$ – locomotive weight (tons),
M_{wagon}^{tarra} – net weight of wagons (tons),
$N_{wagon}^{\emptyset,TEU}$ – average number of TEUs on wagon (TEU),
$M_{TEU}^{\emptyset}$ – average TEU weight in train (tons), while following requirement is valid:

$$M_{TEU}^{\emptyset} \leq M_{TEU}^{max} \tag{5}$$

4.3. Maximum weight of TEU limited by the type of wagon

Maximum weight of TEU is limited by the axle load. It is calculated by following equation:

$$M_{TEU}^{max} = \frac{N_{axles}^{wagon} . M_{axles}^{max} - M_{wagon}^{tarra}}{N_{TEU}^{wagon}} \tag{6}$$

where:
M_{TEU}^{max} – maximum gross weight of TEU (tons),
N_{axles}^{wagon} – number of wagonaxles (axles),
M_{axle}^{max} – maximum axle load (tons):

A – 16,0tons/axle B – 18,0 tons/axle
C – 20,0 tons/axle D – 22,5 tons/axle

M_{wagon}^{tarra} – net wagon weight (tones),
N_{TEU}^{wagon} – number of TEU on the wagon (TEU).

4.4. Maximum train length limitation

The limitation of overall length of train depends on the length of the shortest station track intended for transport (not shunting tracks). This maximum length of train is set in the prescriptions for each line [12]. Maximum number of TEUs per train limited by maximum train length is calculated by this equation:

$$N_{TEU}^{max/train} = \frac{(L_{trai}^{max} - L_{Locomotive})}{L_{wagon}} . N_{TEU}^{max/wagon} \tag{7}$$

where:
$N_{TEU}^{max/train}$ – maximum number of TEU on the train (TEU),
L_{train}^{max} – maximum train length (m),
$L_{locomotive}$ – locomotive length (m),
L_{wagon} – total wagon length (m),
$N_{TEU}^{max/wagon}$– maximum number of TEUs on the wagon (TEU).

4.5. Limitation by the number of TEUs per 1 wagon

Number of TEUs that can be loaded on one wagon is given by loading length and the construction of the wagon.
Conversion TEU units: 1 ISO 1C container = 1 TEU (20)

$$N_{TEU} = \frac{L_{cont}}{20'} \tag{8}$$

where:
N_{TEU} – container length recomputed on number of TEUs,
L_{cont} – container length (feet).

4.6. Conclusion of the model

The final maximum number of TEUs in the train is the lowest number from these:

- number of TEUs per train depending on maximum number of axles per train,
- number of TEUs per train depending on maximum gross weight of train,
- number of TEUs per train depending on maximum length of train,

and given by the minimum value of the maximum number of TEUs resulting from:

- maximum number of axles in train,
- maximum train weight,
- maximum train length.

Capacity means the number of TEUs per train:

$$N_{F-TEU}^{max/train} = min\{N_{i,TEU}^{max/train}\} \tag{9}$$

where:
$N_{F-TEU}^{max/train}$ – final maximum number of TEUs in the train (TEU);
$N_{i,TEU}^{max/train}$– maximum number of TEUs in the train computed through max. number of axles per train, max. train weight and max. train length (TEU).

5. Calculation of maximum transported goods mass and transport performance of one train

In this calculation we assume from the estimated number of TEUs per train. Input for the calculation is the average load of one TEU ($M_{good}^{\emptyset/TEU}$).
Calculation of maximum transported goods mass and transport performance of one train:

$$M_{good}^{max/train} = N_{F-TEU}^{max/train} \times M_{good}^{\emptyset/TEU} \tag{10}$$

where:

$M_{goods}^{max/train}$ – maximum quantity of goods transported by one train (tons),
$N_{F-TEU}^{max/train}$ – maximum number of TEUs transported by train (TEU),
$M_{good}^{\emptyset/TEU}$ – average load of one TEU (tons).

6. Applications of the model on the selected type of trains with the use of common wagons for intermodal transport and with the use of special long wagon

Application of the model is processed for different variants of model train. We processed separately the analysis of train capacity increase depending on maximum train length, maximum number of axles in the train and maximum train gross weight normative.
Calculations are processed via comparison of train with several possible combinations of the wagon compilation and the block train that consist of special long wagon. We realized the calculations for these concrete types of trains:

- block train consisting of the Sgnss wagons,
- block train consisting of the Lgs wagons,
- intermodal transport train set up according to wagon list of actual intermodal transport train which operates on the route Koper (SI) – Zilina (SK).

These wagon compilations are compared with the block train set up from the special long wagons. In the calculations average gross weight of one TEU is considered 11.7 tons. When considering maximum load capacity usage of special long wagon (in chosen variants), then gross weight of one TEU is 16.5 tons. When we compare with the train on route Koper – Zilina, we consider the real average weight of one TEU is 5.9 tons.

Inputs of the Model
Next Tables 1-5 are input data for capacity model.

Table 1
Wagon type Sgnss and Lgs - technical data

		Sgnss	Lgs
Number of axles		4	2
Overall length		19.740 m	14.02 m

In the following calculation of capacity of train compare the four sets of intermodal transport trains with fixed parameters of the train. Train characteristics are - the length 750 m and gross weight of 2,000 t. Locomotive parameters - the length of 16.7 meters and weight of 80 tons. Track category D. The results of the calculations are shown in Table 4 and 5.

Table 4
Overview of the number TEU in the train by a combination of variants and weights of the TEU

	TEU weight (t)	Number of TEU in intermodal train (TEU)		Number of TEU in intermodal train according decisive criteria
		750 m	2,000 t	
Set Sngss – var 1	A – 5.9	111	153	111

Var 3	104	104	70
Var 4	112	108	84

Source: (authors)

Previous calculations have shown that the composition of the set of wagons affects the transport capacity of the train. This change subsequently affects the transport capacity of rail infrastructure – railway track, which can be demonstrated by the following example. We choose double track with capacity of 100 trains in one direction per day. We will use the transport capacity of the previous model train composition variations (Table 5), calculate the capacity to track the number of TEU transported and get the Table 6

Table 6
Overview of track capacity calculation in every variant of train set

	Track section capacity (TEU)		
	5.9 t/TEU	11.7 t/TEU	16.5 t/TEU
Var 1	11,100	10,500	8,100
Var 2	10,400	10,400	8,100
Var 3	10,400	10,400	7,000
Var 4	11,200	10,800	8,400

Source: (authors)

If we want on model the track to transport the previous calculated amount TEU from trains of variants 1-3, by train with the highest capacity (option 4), we can see how much less train would we needed it. That means how many train routes would we have reduced the use of track capacity. The calculated data are provided in the number of trains (Table 7).

Table 7
Reduction of of necessary train, resp. using the tracks capacity

	Number of trains		
	5.9 t/TEU	11.7 t/TEU	16.5 t/TEU
Var 1	1	3	4
Var 2	8	4	4
Var 3	8	4	17

Source: (authors)

7. Conclusion

Table 5 shows the transport capacity of the model train (750 m, 2,000 t) depending on the train composition, which results in advantage of using special long wagons with a single loading area in the all variants.
Table 6 indicate that the maximum transport capacity of the track is in the composition of the model train by special long wagons with a single loading area in all variants.
Table 7 confirms increasing the transport capacity, resp. reducing the number of necessary trains and using the tracks capacity.
Proposed model of transport capacity of the train and railway track based on used types of wagons should optimize the track capacity without any special and expensive solutions and would improve efficiency of operation in transport service and thus contributing to overall satisfaction of customers. Application of the proposed model doesn´t have any special financial expenses, because needs only changing current system of operation.

DECISION SUPPORT SYSTEM FOR FORECASTING THE NUMBER OF RAIL SLEEPING CARS

Marko Kapetanović[1], Milica Šelmić[2], Dragana Macura[3], Rešad Nuhodžić[4]
[1,2,3] *University of Belgrade - Faculty of Transport and Traffic Engineering, Serbia*
[4] *"MonteCargo" AD, Podgorica, Montenegro*

Abstract: The model developed in this paper predicts the number of required sleeping cars in rail transport during peak season and it is based on Artificial Neural Network. This decision support system has several relevant inputs: train route, month, type of sleeping car, number of berths (supply), number of departures, ticket price and GDP; while the output of the system is the number of sold tickets (demand). Additionally, with the aim of better understanding relationships between input and output data, different correlation tests are conducted. The correlation between input variables is tested using Pearson and Spearman rank correlation tests. Further the correlation between a group of inputs and output is tested using canonical correlation. Proposed model is useful especially for rail managers who should make appropriate decisions related to the sleeping cars capacity planning. All considered data are collected from Serbian Railways.

Keywords: prediction, rail sleeping cars, correlation analysis, artificial neural network.

1. Introduction

Prediction of demands on transport market is big challenge for every analyst or manager. The volume of transport demands is depending of many factors, and they can be: economical, sociological, demographical, technological factors, etc. In cases like this, where there are many heterogeneous factors influencing the output observed, classical methods such as regression may lead to inconsistent results. Thus, the implementation of Artificial Neural Network (ANN) is imposed as adequate approach in solving this problem.

In this paper the authors present the extension of the previous model for predicting the number of rail sleeping cars published in (Macura et al., 2015). The suggested model is based on real data from Public Enterprise "Serbian Railway". The inputs of the model are: train route, month, type of sleeping car, number of berths (supply), number of departures, ticket price and GDP; and the output of the system is the number of sold tickets (demand).

The main difference between (Macura et al., 2015) and this paper is in the application of different correlation tests, with the aim of better understanding relationships between input and output data. Correlation between variables is assessed using Pearson and Spearman rank correlation tests. Also the correlation between a group of inputs and output is tested using canonical correlation. The obtained degrees of correlation confirm that selected relevant elements and ANN approach are adequate for this purpose.

After the correlation between inputs and output in the model is tested, Artificial Neural Network model is presented with the purpose to predict the demands for rail sleeping cars.

The paper is organized as follows. After Introduction, in Section 2 correlation between variables is evaluated. Section 3 presents model based on ANN as well as obtained results. And forth, last, section, is dedicated to the conclusion and future research.

2. Correlation between used data

The problem analyzed in this paper is classified as a prediction problem. While doing a forecast, Artificial Neural Network predicts future values of the outputs for a range of inputs. The accuracy of estimate output data depends on many factors, but the most important are the number and relevance of the input data (Rasouli and Timmermans, 2012; Wardman, 2006).

In this paper, the inputs to the system consist of train route, month, type of sleeping car, number of berths, number of departures, ticket price and GDP. The output of the neural network is the number of tickets sold (demand) for sleeping cars (Macura et al. 2015).

We analyzed rail directions of the Serbian railway network from Subotica, Novi Sad and Belgrade to Bar, Montenegro. Data are from 2009 to 2013, including four months: June, July, August and September. Three types of rail cars equipped with berths are considered: couchette cars – Ac and Bc, and sleeping cars – WL.

The correlation between variables is evaluated using two widely used statistical tests – Pearson's and Spearman's rank correlation tests. The aim was to analyze the relationship between variables, thus in orders to obtain consistent results two commonly used tests were applied and the results are compared.

Pearson's correlation coefficient was discovered by Bravais (1846), but the first who described the standard method of its calculation was Karl Pearson (1896). Pearson's correlation coefficient represents a measure of the strength of the linear relationship between two variables. An important assumption regarding this correlation measure is the normality of the variables analyzed (Hauke and Kossowski, 2011).

In addition to Pearson's work, Spearman (1904) introduced new correlation measure between two variables. Spearman's rank correlation coefficient represents a nonparametric (distribution-free) rank statistic aiming to measure the strength of the (monotone) association between two variables.It is often used when the distribution of data makes Pearson's correlation coefficient misleading. Compared to Pearson's correlation coefficient, it does not represent the measure of linear relationship between two variables, but it assesses how well an arbitrary monotonic function can describe the relationship between two variables, without making any assumptions about the frequency distribution of the variables (Hauke and Kossowski, 2011).

Results of Pearson's and Spearman's correlation tests are presented in Tables 3 and 4. Both tests showed similar results. Considering statistically significant coefficients, both tests indicated relatively high correlation coefficients between input variables representing year (x1) and GDP (x8), as well as between type of sleeping car (x4) and ticket price (x7). Negative sign of the latest coefficient may be a consequence of arbitrarily assignment of numerical values to different types of sleeping car. Regarding output variable (y), which represents the number of sold tickets, both tests indicated high and statistically significant correlation between output variable and the input variable which represents number of berths (x5). All other coefficients have a relatively low value, are not statistically significant, or both.

Quantification of the intensity of dependence between two different sets of variables may be conducted by canonical correlation analysis (Kráľ and Roháčová, 2013). In addition to previous tests, this paper also aims to evaluate the dependence between the set of inputs, containing eight variables, and the set of outputs, which, in this case, consists of only one variable. For this purpose canonical correlation is used. Results are presented in Table 5. The raw canonical coefficients can be used to generate canonical varieties of input and output sets, and are interpreted in a manner analogous to interpreting regression coefficients. High value of canonical correlation coefficient indicated strong dependence between the set of inputs and the output.

Table 5
Canonical correlation analysis

	Variable	Coefficient
Raw coefficients for the first variable set	Y	0.001
Raw coefficients for the second variable set	x_1	-0.033
	x_2	-0.043
	x_3	0.050
	x_4	0.013
	x_5	0.001
	x_6	0.000
	x_7	0.000
	x_8	0.070
Canonical correlation		0.932

In order to test if a canonical correlation is statistically different from zero, different test are applied, and the results are presented in Table 6. Results confirmed that the obtained canonical correlation coefficient is statistically significant.

Table 6
Tests of significance of canonical correlation

Test	Statistic	F	Prob>F
Wilks' lambda	0.13068	85.6519	0.0000
Pillai's trace	0.86933	85.6519	0.0000
Lawley-Hotelling trace	6.65257	85.6519	0.0000
Roy's largest root	6.65257	85.6519	0.0000

3. Results of Artificial Neural Network Model

The Artificial Neural Network (ANN) is an approach that relies on a simplified brain model. The processing tasks are distributed over many neurons (nodes, units or processing elements). Even though individual nodes are capable of simple data processing, the main power of a neural network is the result of connectivity and collective behaviour between the nodes (Teodorović and Šelmić, 2012).
The ANN model is developed and presented with details in (Macura et al., 2015). The structure of the model, with all inputs and output, is presented in following figure.

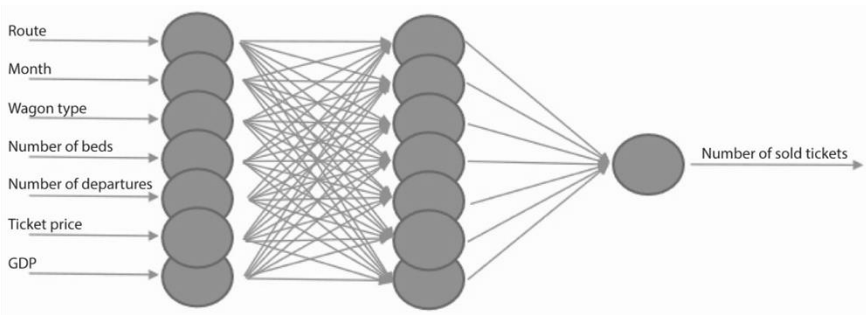

Fig. 1.
The structure of the ANN model

For the neural network, three types of patterns have been taken into consideration. The first data set represents the data which are used for the neural network training, and the network is consequently adapted in accordance with the mistakes made in this iteration. The second one is used for validation. These data are used to generalize the network, and to end training process at the moment when the neural network stops making further improvements. Finally, the third one is used for testing. This data set does not influence the training process, and by extension, it represents an independent measure of the neural network’s performance during and after the training. In our code, in Matlab, this pattern makes 24% of all data (Macura et al. 2015).
The model is developed in Matlab, and final results shows high correlation between output and target data (Figure 2).

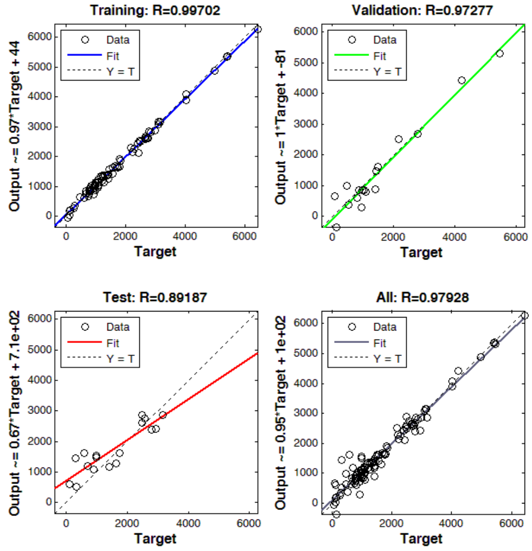

Fig. 2.
Relations between the output data and target results obtained by Matlab

As it can be seen from Figure 2 during the training phase, the artificial neural network has predicted the number of sold tickets, which reflects the reality in 99,7% of cases. When the test data were processed, an accurate prediction of the number of tickets sold was 89,2% in all cases. The regression in the case of test data is shown in Fig. 2, where the x-axis shows the target values (the number of tickets sold in the past), while the y-axis shows the output values (the number of tickets obtained by means of neural network's prediction).

4. Conclusions

The model presented in this paper forecast the number of rail sleeping cars, based on several relevant factors. For the first time, the correlation between inputs and output of the model is tested, and the obtained correlation coefficients confirmed the relevance of all considered factors and the validity for using ANN in solving the problem. The model for prediction is based on the ANN, and the model is tested on the real data from PE "Serbian Railways".
There are some also relevant factors, such as: civil standard, the quality of service, etc., which can be considered and relatively easily included in the model. Uncertainty and imprecision of such inputs values can be considered by using the fuzzy sets. The authors' future researches are related to this kind of solutions.

PREDICTIVE MODEL OF VIBRATIONS INDUCED BY RAILWAY TRANSIT IN URBAN AREAS

Manuela Esposito[1], Laura Mancini[2], Francesca Russo[3]
[1,2,3] *University of Naples "Federico II", DICEA (Department of Civil, Architectural and Environmental Engineering), Italy*

Abstract: The structural increase of rail networks in recent years, aimed at transforming existing lines in high speed and/or high capacity lines, implies an increase of stress resulting from a more intense exercise and a more rapid evolution of the decay of rolling stock and infrastructure, highlighting noise and environmental damage caused by vibrations. In recent years, rail transport systems have often been subjected to complaints from the population living near railway lines, where the annoyance is usually caused by the emission of noise and vibrations. This problem, coupled with the growing sensitivity to the environmental impact, requires the increasing study of vibrations and sound , both for new infrastructure and for the adaptation and the upgrading of existing lines. Railway vibrations are secondary localized wave motions, due to the dynamic interaction between several complex mechanical systems: rolling stock, wheels, rails and trackbed. Such vibratory motions propagate in the ground-born, generating different dynamic effects on the receptors; these effects can disturb or damage facilities and people. The evaluation of the vibrational noise due to railway transport systems requires the analysis of the whole phenomenon: the generation, due to the interaction between the train and the way, is considered first; then the propagation phenomenon, influenced by surrounding soil, is studied. The aim of this research is to promote a predictive methodology of vibrations induced by metropolitan lines in Naples, due to rail defects; the propagation phenomenon is studied through a "hybrid" model, divided into two sub-models: the former, called "generation model", analyzes the dynamic interaction between the rolling stock and railway equipment; the second, called "propagation model", studies the propagation of vibration waves by means of the finite element method, applying the interaction forces on the superstructure. An adequate data set of experimental vibrations measurements is used to validate the proposed methodology.

Keywords: railway, vibrations, ground-born, rail defects.

1. Introduction

Starting in the 60s, noise has become a matter of great importance, because with its increase the population started to become aware of related problems. In 1996 during the European Commission Green Paper in Brussels, it was estimated that 20% of the population of Western Europe lived in areas where the ambient noise level was greater than 65 dB, and as much as 60% of the population lived in areas where the noise level was more than 55 dB (Future Noise Policy, 1996).

The main source of noise was represented by roads and railways traffic. Like noise, vibrations generated by rail traffic also cause annoyance; their modeling has become increasingly important in recent decades, mainly because it is linked to the assessment of the performance expected from the countermeasures adopted. Vibrations generated by the passage of railway vehicles are the result of several components, characterized by different properties of amplitude, frequency and phase angle. Vibrations usually occur at frequencies lower than 50 Hz, while at higher frequencies the phenomenon attenuates very quickly; in other words, vibrations are contained in a frequency range from 0 to 100 Hz, while noise occurs when the signal frequency is comprised between 30 and 2000 Hz (Esveld, 2001).

The amount of energy transmitted depends, in a significant way, on some factors such as the roughness of the wheels and the rails, or from the resonance frequencies of the suspension system of vehicles and the track support system. The soil acts as a filter, which generally attenuates the intensity of the vibrational components at all frequencies, except to their own natural frequencies of resonance, which amplifies the amplitude of vibrations themselves. Once they have reached building's foundations, the motion field is transmitted from the ground to the structure, changing is amplitude and frequency content.

Like the ground, the building may also amplify or attenuate the vibration level, according to the type of foundation, the type of material, the number of floors and the geometry of the structure (Clough and Penzien, 2003). Vibrations produced by trains typically do not cause structural problems, but they may produce significant distress to people who are located inside buildings. In fact, vibrations can produce perceptible movements of the floor or windows, shake objects on shelves or attached to the walls, or even roaring sounds. The wheels of the trains move on the rails by creating the vibrational energy that is transmitted to the outside through the support system of the rails.

2. State of art

Rail vibrations induced by the passage of the convoy are generated by three families of forces: the weight of the vehicle in motion, the inertial reaction of the vehicle under the effect of vertical undulation on a non-deformable rail and the force of inertia of the vehicle due to the movement of the rail. The first two groups of forces do not depend on the displacement of the rail and the mathematical formulation is easily expressed through a problem of forces with moving application point; the formulation of inertial forces of the vehicle, connected to rail vibration requires, however, references to the rail accelerations viewed by a mobile observer (moving with the vehicle itself). In addition, it is

[1] Corresponding author: manuela.esposito@unina.it

necessary to express the equation of equilibrium of two dynamic systems, the vehicle and the track, in correspondence of a moving contact point (Castellani, 2000). Defects of a railway line generate vertical acceleration on the unsprung masses of the vehicle passing over it. In this sense acceleration can be considered due to the rail's anomalies or geometric/structural abnormalities.

The defects attributable to the rail considered in this study are undulations with small wavelength. In order to predict the vibration level caused by the passage of a train, it is possible to resort to a mathematical or numerical model.

While in recent years numerical models based on F.E.M. (Finite Elements Method) or F.D. (Finite Differences) method has become widespread, in the past analytical methods were used, having simple models explanatory of the factors governing the phenomenon; moreover analytical models are characterized by a simple calibration based on experimental measurements; on the other hand, the use of such simplified models did not allow to consider complex geometries or all possible scenarios.

Despite the advantages in terms of complexity of the model, available software present numerical instability, involving that the convergence to stable solutions is not always guaranteed and it is difficult to calibrate a unique model, reliable for boundary conditions that are different from those in correspondence of which the measures in the field were carried out. For example, the choice of size of the mesh elements, the extension of the entire model, the damping of the ground and the number of points to be loaded depend on dynamic characteristics and speed of the train (Roma et al., 2010).

Several studies have focused on the vibrations induced by traveling loads, presenting different theories; some of them have been referred to the classical theories: continuous or discrete contact models.

(Castellani, 2000) analyzed and revised Fryba (Fryba, 1972) and Grassie (Grassie et al., 1982) theories, presenting a mathematical model that faithfully reproduces vibrations for a range of frequencies between 0 and 80 Hz.

(Lombaert and Degrande, 2001) introduced and validated an analytical model for the prediction of vibrations induced in the ground by the passage of vehicles (referring, in this study, to road loadings). It consists of a 2D model of the vehicle which calculates loads coming from the axes starting from the study of the longitudinal profile of the road, while induced vibrations are calculated referring to the Betti-Rayleigh Reciprocity Theorem. In subsequent studies they verified that the model overestimates high frequencies, affecting the prediction of vibrations generated in the ground. However, since the overestimation is gradually reduced at high frequencies and with distance from the source, authors were able to conclude that soil characteristics are to estimate the vibration level.

(Sheng et al., 2002) proposed the application of the Discrete Wavenumber Method - DWM, based on fictitious forces, implemented in a F.E.M. or a B.E.M., in order to describe the propagation of waves in the ground, the movement of the train in the tunnel and the propagation of the waves in that direction.

(Pezzoli, 6/2004) proposed an approach based on analytical models, validated through experimental and mixed (experimental and analytical) data. The author points out that the definition of a spectrum of vibrational level is closely related to several parameters, such as stiffness and energy dissipation capacity of primary suspension of the bogie, armament-vehicle interaction, operating conditions of the line, alteration of wheel-rail interface, train speed, type and the size of the infrastructure, section of the embankment, dynamic-structural characteristics of viaducts, mass and characteristics of foundations and piles, thickness of infrastructure and tunnels walls, nature and characteristics of the soil, structural characteristics of the buildings, mass of the rail, characteristics of the rail fastening systems. Each of these parameters is described using an analytical model. Experimental models are obtained by analytic interpretation of operational measures carried out during the passage of trains on specific railroad equipment and for a particular vehicle used by the transport system, complemented by dynamic load tests on the same equipment.

(Lai et al., 2005) developed a predictive technique of vibrations induced by a metropolitan tunnels and perceived in buildings. The representative function of the load induced by the train is defined with reference to two generation mechanisms: the first is the quasi-static deformation caused by the load in correspondence of the axle, the second are dynamic forces generated in correspondence of the undulations of the rail, represented by PSD.

(Cantisani et al., 2015) propose, in their F.E.M. model, the introduction of an absorbent layer placed at the ends of the solid representing the ground, in order to simulate what was historically schematized by the spring-damper assembly, concluding that the introduction of this layer allows to obtain results close to those calculated with analytical solutions, although the model is not exactly able to reproduce the vertical asymptote, which corresponds to the passage of Rayleigh waves in the point of observation.

Finally, a small number of studies in the literature focused on the analysis of the dynamic response of the coupled systems rolling stock/superstructure and superstructure/ground.

(Lei and Noda, 2002) considered track irregularities as the source of system excitation and represented them as a stationary and ergodic process, distributed as a Gaussian random variable represented recourring to the America Railway Standard PSD. Furthermore, the dynamic equation of the vehicle is described by an analytical model, by means of a system of 10 equations and 10 variables (10 degrees of freedom of the analyzed vehicle), whilst the dynamic equation of the rail is obtained through a F.E.M. The advantage of analyzing separately the vehicle and the track with iterative schemes lies in the fact that it is possible to easily solve the nonlinear problem which results from the calculus of interaction forces with the conventional formula of Hertz, thus enabling to avoid the asymmetry of the equation resulting from the coupling of dynamic systems.

(Nicolosi et al.,2012) and then (D'Apuzzo et al., 2014) proposed a model, called "hybrid model", applied to underground metros (Turin and Naples – Line 1) and that can be splitted into two sub-models, which follow the conventional phenomenological approach to the problem: a generation model which analyzes the dynamic interaction between the rolling stock and the superstructure, and a propagation model, which studies the transmission of vibrations in the ground surrounding the tunnel. In particular, the former is an analytical model which summarizes the superstructure as a Winkler beam on supports consisting of springs and dampers, while the latter has been achieved by making use of the F.E.M., given the complexity of the analytical schematization of the gallery.

3. The case study: Circumvesuviana Line of Naples

The aim of this paper is to apply the hybrid model to a section of the S. Giorgio – Volla Circumvesuviana Line of Naples, placed outside the gallery, and verify that the model reproduces also in this case the induced vibration, by comparison to experimental measurements. The Circumvesuviana railway connects about 50 municipalities around Naples and has a network of approximately 145 km. The main part of the network is realized with the continuous welded rail profile 50 UNI. The superstructure is almost entirely with ballast. It is characterized by a reduced gauge, 950 mm, less than the standard of other Italian railway networks.

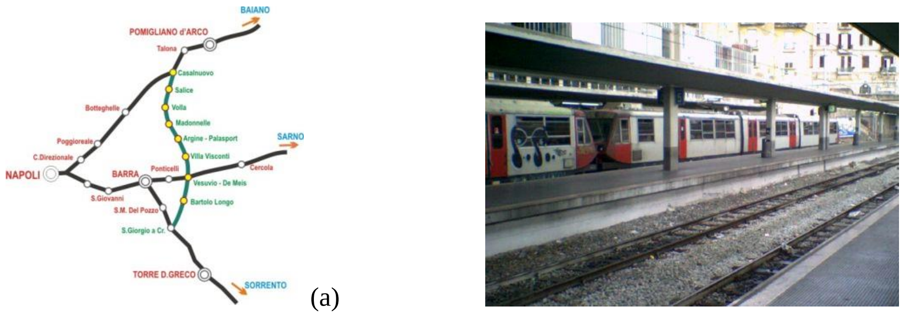

Fig. 1.
Circumvesuviana Line of Naple: Railway Network (a) and Superstructure (b)
Source: http://www.eavsrl.it/web/it

The rolling stock, ETR FE 220, is locked to the composition of three car bodies on four bogies. Each electric train is bidirectional and has two cockpits, with an overall length of 40m. Each coach is connected via a secondary suspension system to the bogies, in turn connected to the axle via a primary suspension.

3.1. The analytical model

The analytical model, also called "generation model", reproduces the interaction between rolling stock and superstructure, by means of a set of equations governing the phenomenon. Equations describe the coupled behavior of the superstructure and the vehicle. In this study, the superstructure has been modeled as a Winkler beam resting on a continuous single layer of springs and dampers, considering 21 discrete contact points at the rail-subgrade interface.
The vehicle, in this case, is described through a discrete model made up of lumped mass and rigid bodies interconnected through springs and dampers described through mass and inertia moments of the car body, bogies and wheel axles and stiffness and damping characteristics of primary and secondary suspensions systems (Ramasco, 1993) (Esveld, 2001) (Iwnicki, 2006).The model of the Circumvesuviana rolling stock is made up of seven masses (car body, two bogies and four wheel sets), interconnected through springs coupled to dumpers. Car body and bogies have the vertical and the pitching degrees of freedom, while wheel sets, because of elastic wheels, only have the vertical degree of freedom, resulting in a 10 degrees of freedom model. The excitation of the system is represented by the irregularity of the runway, which, in absence of direct measurements, is a random phenomenon and is here represented by Frederich PSD (Forrest and Hunt, 2006):

$$S(f) = \frac{1}{v} \cdot \frac{a}{(b + {f}/{v})^3} \quad (1)$$

where:

- S(f) is the PSD of the rail defect as a function of temporal frequency, in m^2/(cycles/s),
- f is the temporal frequency of rail defects, in cycles/s,
- v is the velocity of the train, in m/s,

- a and b are “unevenness” and “waviness” respectively.

The calculus of interaction forces in the system vehicle-superstructure-ground passes through the definition of:

- interaction forces between vehicle and superstructure:

$$F_{wr} = k_H \cdot (y_w - y_P - y_r) \quad (2)$$

- interaction forces between the superstructure and the ground:

$$F_{rs} = (k_R + i \cdot \omega \cdot c_R) \cdot (y_r - y_s) \quad (3)$$

where:

- k_H it is the Hertzian stiffness of the wheel-rail interface;
- k_R, c_R are stiffness and damping characteristics of under-rail plates;
- y_W is the shift of the vehicle in correspondence of the contact with the rail in the frequencies domain;
- y_P is the track irregularity in the frequency domain;
- y_r is the displacement of the superstructure in correspondence of the contact with the vehicle in the domain of frequencies.

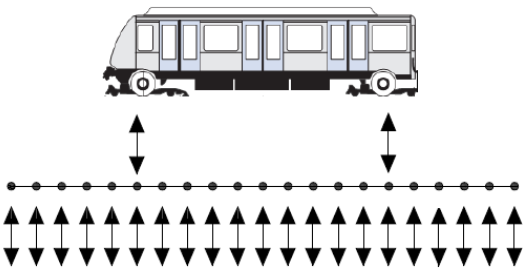

Fig. 3.
Scheme of interaction forces

Two equation sets are generated: the first is made up of 4 equations, (one for each contact point between the vehicle and the superstructure), the second consists of 21 equations, (one for each superstructure-ground contact points: the study area is 20 meters long and interaxle spacing between two consecutive under-rail plates is 1 m).

$$\begin{cases} F_{w1r} = K_H\left(\sum_{m=1}^{4} H_{w1m} \cdot F_{wmr} - Y_{p1} - H_{rw1wm} \cdot F_{wmr} - \sum_{i=1}^{n} H_{rw1si} \cdot F_{rsi}\right) \\ \vdots \\ F_{wmr} = K_H\left(\sum_{m=1}^{4} H_{wmm} \cdot F_{wmr} - Y_{p1} - H_{rwmwm} \cdot F_{wmr} - \sum_{i=1}^{n} H_{rwmsi} \cdot F_{rsi}\right) \end{cases} \quad (4)$$

$$\begin{cases} F_{rs1} = (K_R + j \cdot \omega \cdot C_R)\left(\sum_{m=1}^{4} H_{rs1wm} \cdot F_{wmr} + \sum_{i=1}^{n} H_{rs1si} \cdot F_{rsi} - \sum_{i=1}^{n} H_{s1si} \cdot F_{rsi}\right) \\ \vdots \\ F_{rsn} = (K_R + j \cdot \omega \cdot C_R)\left(\sum_{m=1}^{4} H_{rsnwm} \cdot F_{wmr} + \sum_{i=1}^{n} H_{rsnsi} \cdot F_{rsi} - \sum_{i=1}^{n} H_{snsi} \cdot F_{rsi}\right) \end{cases} \quad (5)$$

where:

- H_{w1m} is the FRF of the vertical displacement of the first vehicle wheel axle induced by a unit force applied on the *m*-vehicle wheel axle ;
- H_{rw1wm} is the FRF of the vertical displacement of the rail point under the first wheel axle induced by a unit force applied on the contact point between the *m*-wheel axle and the rail;
- F_{rsi} is the vertical interaction force in the *i*-contact point between the rail and the underling soil/structure;
- Y_{p1} is the spectrum of rail defects experienced by the first wheel axle;
- H_{rs1wm} is the FRF of the vertical displacement of the rail point located over the first contact point between the rail and the soil/structure, induced by a unit force applied on the contact point between the *m*-wheel axle and the rail;
- H_{rs1si} is the FRF of the vertical displacement of the rail point located over the first contact point connected to the soil/structure, induced by a unit force applied on the *i*-contact point between the rail and the soil/structure;
- H_{s1si} is the FRF of the vertical displacement of the soil/structure point located in the first contact point between the rail and the soil/structure, induced by a unit force applied on the soil *i*-contact point between the rail and the soil/structure.

3.2. The numerical model

The geometry of the FEM model, made using the software Lusas Alhambra S.r.l., is the result of a calibration analysis of the damping area and is based on the characteristics of the ground.
In absence of stratigraphic site test, we considered as a reference point information contained in " Il sottosuolo di Napoli " (Comune di Napoli, 1967).

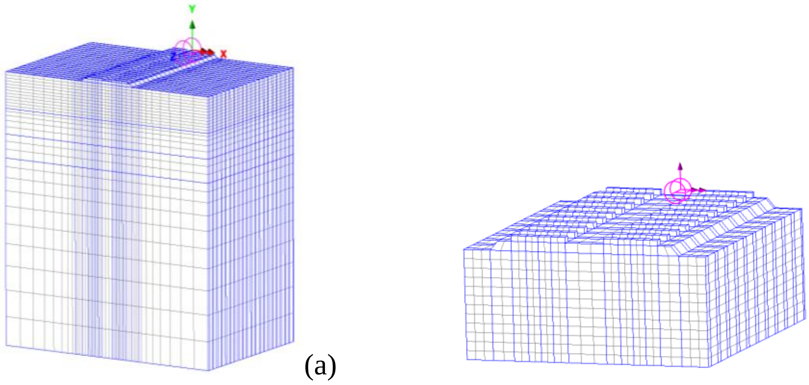
Fig. 4.
Stratigraphy in the vicinity of the study area

The study area is surrounded by a damping area in order to simulate the energy dissipation phenomenon due to material damping, by recurring to the Rayleigh approach. The cylindrical surface is constrained in both radial and tangential directions, while constraints are also placed on the plane of symmetry along the z-axis in order to fulfill the requirement of symmetry.Pulse vertical forces are applied on sleepers on the plane of symmetry, in order to derive the Frequency Response Functions (FRF), to be introduced in the mentioned equation sets. A static analysis allowed to verify the congruence of the model.



(a) (b)

Fig. 5.
3D FEM model developed for the propagation model: complete model(a) and study area (b)

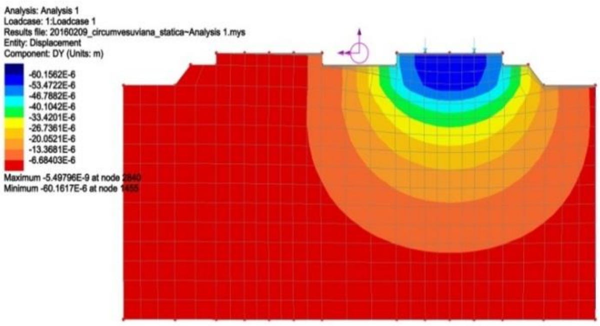


Fig. 6.
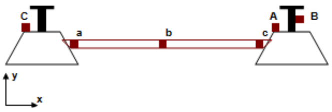
Deformed mesh (static analysis) of the propagation model

3.3. Experimental data

Through the use of accelerometers acceleration measurements in amplitude and frequency content were obtained. Three sensors were arranged in points A, B, C; in each of them an accelerometric block with two sensitivity axes oriented according to the Y axis and the X axis was installed. The sampling frequency was 1000 Hz. A section named "Section 4", located 6600,37 m far from S. Giorgio station, was chosen for the simulations.



Punto	Tipo di sensore	Asse di sensibilità
A	Accelerometro	X,Y
B	Accelerometro	X,Y
C	Accelerometro	X,Y

(a)

(b)

Fig. 7.
Scheme of accelerometers arrangement (a) and Localization of the monitoring section (b) (STRAGO, 2003)

In order to adapt the Frederich PSD (referred to the speed) to the accelerometer measurements available, the application of the integration method is needed.
Consider a single-degree-of-freedom system undergoing sinusoidal excitation. The velocity is obtained by taking the derivative, whilst the acceleration is obtained by taking the derivative of the velocity:
These relationships can be applied to the PSD functions
Let:

- DPSD = displacement power spectral density
- VPSD = velocity power spectral density
- APSD = acceleration power spectral density

where each PSD is function of the frequency f (resulting an angular frequency $\omega=2\pi f$)
Resulting relationship is:

$$APSD = \omega^4 \cdot DPSD = (2\pi f)^4 \cdot DPSD \tag{6}$$

3.4. Results

Results from the numerical simulations were finally confronted with experimental data.
The comparison, in the frequency domain, is shown in Figure 8.
For the Nyquist-Shannon theorem the maximum frequency investigated is 500 Hz, since a sampling frequency of 1000 Hz was adopted. As it can be observed in the figure, a fairly good agreement between the numerical simulation and experimental data in frequency domain was registered.
As far as the comparison in the time domain is concerned, unfortunately we were not able to do it, since the company who carried out the monitoring campaign gave us results analyzed in the frequency domain; furthermore they were subjected to an average and low-pass filter, so it was impossible to reconstruct the signal in the time domain by inverse Fourier transform.

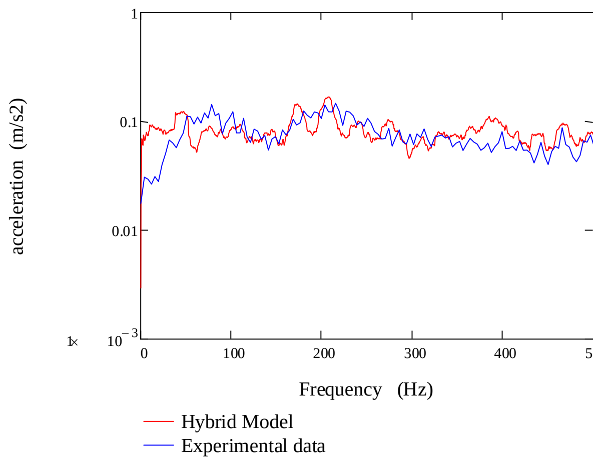


Fig. 8.
Comparison between experimental data and numerical simulations in the frequency domain

4. Conclusions

The purpose of this research was to study a predictive model of vibrations induced by the passage of railway vehicles, calibrated on the basis of the comparison between results coming from numerical simulation and a vibration monitoring campaign.

The innovation of this study, compared to other present in the literature, is that the "hybrid model” is the result of a combination of analytical and numerical models, thereby taking advantage of the simplicity and manageability of the former, as well as the versatility and adaptability to multiple scenarios of the latter.
The simulation is over, of course, through the study of the geometry of the site, the soil characteristics and the definition of analytical models to outline the superstructure of the metro lines under study, as well as the convoys.
Results demonstrate that there is a satisfactory agreement in the comparison between experimental data and numerical simulations (output of the "hybrid" model); registered variances may be attributable to mistakes made during the acquisition of the signal.
Furthermore the PSD is a useful tool for the simulation of a random phenomenon, such as the irregularity of the runway, in absence of direct measurements.

NEW APPROACHES OF STRATEGIC CONTROL IN RAILWAY TRANSPORT IN THE CONTEXT OF SUSTAINABLE MOBILITY AND COMPETITIVENESS

Anna Dolinayová[1], Juraj Čamaj[2], Jozef Daniš[3]
[1,2,3] University of Žilina, Faculty of Operation and Economics of Transport and Communications, Department of Railway Transport, Univerzitna 8215/1, 010 26 Žilina, Slovakia

Abstract: Company strategy cannot be created without the realization of detailed analysis of the company surroundings (external analysis) and the company itself (internal analysis). Strategic analysis of the company surroundings is a process to monitor and evaluate competition, so that the company can eliminate or reduce threats on the one hand and make use of opportunities on the other. Strategic internal analysis is aimed at the strengths and weaknesses of the company. Identification of these factors makes it possible to create strategy with respect to existing or future enterprise production factors. This article deals with new approaches to assist of company management by controlling the strategic analysis phase. It is the result of theoretical and methodological research for the realization of strategic analysis of railway companies with respect to transport market specifics, and the possibilities to increase railway transport competitiveness. Based on this, we designed and validated methods suitable to improve upon relevant strategic analysis. These methods were validated using model situations.

Keywords: competitiveness, methods of strategic analysis, monitoring, railway transport, strategic controlling.

1. Introduction

The basic objective of strategy management is to estimate future trends and to formulate strategy tasks so that the company will have a competitive advantage of a longtime existence on the market. This role can be achieved on the basis of synthesis of available information and knowledge about the company and their environment. Strategy controlling should fulfil mainly informational, analytic and coordinate roles during the analysis, creation and implementation phases. The analysis phase should afford the all relevant information about the past development of internal and external business indicators and their assumed development. Controllers must know and applicate appropriate methods for realization this analysis. In rail companies, the application of general methods and techniques of strategy analysis requires not only their adaptation to concrete conditions but often transformation of the methods and techniques to match the specific needs of railway transport.
Nowadays, strategy management theory is developed by two separate schools:

- Ansoff prefers target orientation of strategic development; while
- Mintzberg deals with process-oriented strategic development.

Ansoff developed the method of strategic analysis 27 years ago Ansoff (1979). He dealt with the issue of adapting corporate strategy around business and their changes in the works “The New Corporate Strategy” (Ansoff, 1998) and “Optimizing profitability in turbulent environments. A formula for strategic success” (Ansoff, 1993). Porter has been concerned with the issue of competitive strategy and its patterns of the industrial structure and value chain since 1980 (Porter, 1980). Recently, Porter has dealt with the impact of intelligent products to change competitiveness in companies (Porter and Heppelmann, 2014; Porter and Heppelmann, 2015).
Presently, when the environment of companies is not predictable, it is not possible to create strategy with explicit targets. Companies need flexible strategies that for changing conditions (Mintzberg, 1987). Mintzberg criticized the traditional concept of strategy planning and defined five basic strategies (Mintzberg's five Ps of Strategy): Plan, Ploy, Pattern, Position, Perspective (Mintzberg, 1994).
The liberalization of the rail transport market entails increases in competitiveness for companies that provide the services for passengers or freight rail transport. Therefore, companies must differentiate their business activities so as to be successful in a competitive market. Such differentiation in combination with a rapid response to changes in the business environment and adaptation to the requirements of customers increases the demands on management, which must include the amount of information from external and internal environments of the company.
Controlling becomes one of the most important areas of support in business management. In railway undertakings, the existence of an effective system of controlling a necessary condition for business success with respect to specific business activities is often carried out internationally. In the area of strategic controlling, problems in the application of generally applicable methods arise for the conditions of rail transport. The solution to this problem is to design generally applicable methods of strategic analysis on the conditions of companies providing rail transport services.

2. Material and methods

The creation of strategy must be based on a thorough strategic analysis of corporate surroundings and the company itself. Currently, there are many methods and techniques that are more or less suitable for the realization of strategic analysis on companies providing services in the railway sector.

[1] Corresponding author: anna.dolinayova@fpedas.uniza.sk

2.1. Methods of strategy analysis

Strategy analysis is the fundamental part of strategy controlling. While strategy managers create and implement new strategies in companies, the strategic role of the controller is provided with the necessary information to create strategy, i.e. to realize strategic analysis.
Strategy analysis is performed in two basic areas:
- Analysis of the company's environment; and
- Analysis of the company.

Analysis of the company's environment can by realized by:
- PEST analysis, and
- Porter's five forces analysis.

PEST analysis or extended version (PESTLE analysis) deals with analysis of the global company environment. Aguilar is considered to be its founder. In 1967, he published the work "Scanning the Business Environment," in which the determined four basic sectors affecting companies: Economical, Technical, Political, and Social. PESTLE analysis is expanded to include Legal and Environmental. Currently, it is used not only for strategy analysis of company environment, but also for the evaluation of the business environment of countries (Palova, 2014).
Porter's five forces model deals with the competitive environment of companies (i.e. sector competition). These forces include (Porter, 2008):
- Threat of new entrants;
- Threat of substitutes;
- Bargaining power of buyers;
- Bargaining power of suppliers; and
- Industry rivalry.

Strategy analysis should provide a comprehensive overview of the internal environment of the company: its aim is to identify the key skills and competencies of the company. The most commonly used methods of strategic analysis of the company include (Eschenbach, 2000):
- Potential Analysis;
- Strategic Balance;
- Analysis of the value chain and cost structure; and
- Strategy Business Unit (SBU) analysis.

Potential analysis focuses on the existing potential success of the company and the strategic resources of the company. First, it analyzes the strengths and weaknesses, and then draws up a list of successes and failures and their causes in individual areas of the company (such as production, logistics, sales, human resources, etc.). It must be developed to quantify the reasons for the successes and failures.
Strategic Balance involves the company's dependence on different stakeholders. Mann dealt this problem for the first time. He proposed five major corporate functions and corporate resources to build strategic balance – capital, staff, material, sale and know-how (Mann, 1989).
Company dependence on individual interest groups is almost always passive (enterprise depends on stakeholders) but can also be active (stakeholders are dependent on the company). After establishing a list of active and passive dependence, points are assigned to each interest group. Determining point scale and the actual allocation of points to the different stakeholders is subjective in nature. Strategic balance shows free space for company dealing. A sufficiently large space is considered if the sum of points of strategic balance is greater than half the maximum possible number of points.
Analysis of the value chain and cost structure of the company is used to assess the overall performance of the business process creation. The aim of this analysis is to optimize the value chain (Ghemawat, 2002). In this analysis, it is necessary to distinguish between primary and secondary activities. Primary activities are the main activities of the company, which contribute most to the profit (e.g. product production), whereas secondary activities are most often used to support the primary activities (e.g. logistics, controlling, enterprise administration, etc.).
SBU analysis deals with the product portfolio of the company. A strategic business unit is a unit or activity of the enterprise (e.g. specific product or service) that can be monitored and evaluated in isolation in terms of kind and value indicators, as well as in terms of the external environment of the company. Presently, the BCG Matrix, a newer version of the GE / McKinsey Matrix, is used in the analysis of strategic business areas.
The BCG Matrix is a portfolio model developed by the Boston Consulting Group. The BCG matrix is a simple way of plotting the firm's different business portfolios onto the same matrix, providing some guidance as to how the company's resources should be allocated across the different business units. The BCG matrix considers two elements to form its four quadrants: Growth rate of the market, and Relative market share. The growth rate of the market dimension is used as a proxy measure of the attractiveness of the market, with high-growth markets being seen as more attractive and offering more potential and opportunity. Relative market share is used as a surrogate of competitive strength. The larger the firm's market share relative to its largest competitor, the stronger the firm is in the marketplace (Fripp, 2015).
The GE/McKinsey Matrix was originally developed by McKinsey & Co. consultants in order to help the American conglomerate General Electric manage its portfolio of business units. The nine-box matrix plots the BUs on its nine cells that indicate whether the company should invest in a product, harvest/divest it, or perform further research on the

product and invest in it if there are still some resources left. The BUs are evaluated on two axes: industry attractiveness and the competitive strength of a unit. Industry attractiveness consists of many factors that collectively determine the competition level in it. There is no definite list of which factors should be included to determine industry attractiveness, but the following are the most common (McKinsey & Co., 2008):

- Long run growth rate
- Industry size
- Industry profitability: entry barriers, exit barriers, supplier power, buyer power, threat of substitutes and available complements (use Porter's Five Forces analysis to determine this)
- Industry structure (use the Structure-Conduct-Performance framework to determine this)
- Product life cycle changes
- Changes in demand
- Trend of prices
- Macro-environment factors (use PEST or PESTLE for this)
- Seasonality
- Availability of labor
- Market segmentation.

Along the x-axis, the matrix measures how strong, in terms of competition, a particular business unit is against its rivals. In other words, managers try to determine whether a business unit has a sustainable competitive advantage (or at least a temporary competitive advantage) or not. If the company has a sustainable competitive advantage, the next question is: "For how long it will be sustained?" The following factors determine the competitive strength of a business unit (Jerevicijus, 2014):

- Total market share
- Market share growth compared to rivals
- Brand strength (use brand value for this)
- Profitability of the company
- Customer loyalty
- VRIO resources or capabilities
- Business unit strength in meeting industry's critical success factors
- Strength of a value chain
- Level of product differentiation
- Production flexibility.

2.2. Application and transformation methods on the conditions of rail companies in the Slovak Republic

In rail companies, strategic analysis can be carried out using the methods that were described in the precious section, but these methods must be adjusted to railway transport conditions. The process of realization of strategy analysis consists of analyzing companies' environment and strategy analysis of the company, exactly the same as in any other sector.

2.2.1. PESTLE analysis

It is very important to realize the analysis of the global environment in the individual area. PESTLE analysis can be reduced to PEST analysis in view of the fact that the environmental area is a part of transport policy. In the individual part of PESTL analysis, important factors can be identified that affect rail companies.

Political factors. It is needed to analyze mainly European and national transport policy in the rail transport area. European transport policy is embedded in the document "Roadmap to a Single European Transport Area – Towards a competitive and resource efficient transport system" about the future of European transport by 2050. In this document, initiatives are designated to realize the vision of a competitive and sustainable transport system. From the basic vision, priorities and objectives of the strategy defined in rail transport in the European transport policy, it is also based on national transport policy: "Strategy of development of transport SR by the year 2020".

Global objectives are developed into specific objectives and priorities, along with measurable indicators. As part of strategic controlling, analyzing transport policy provides information on planned activities in the field of railway transport, which in future may not only affect competition in the rail transport market, but also in the transport market as a whole.

Economic factors. The basic areas that must be analyzed include economic growth pursued through macroeconomic aggregates, such as gross domestic product (GDP), gross national product, personal disposable income, output, etc. The relationship between the volume of freight and GDP across the EU varies. The index of total freight to GDP index was, in the period 2000–2010, according to Eurostat, in Slovenia + 66% in Germany, + 1% in the Czech Republic 14%, in Poland + 34% and -14% in Slovakia.

Equally disproportionate is the development between different transport modes. The development of passenger transport is significantly influenced by the living standards of the population and the quality of public mass passenger transport. If they are not provided with quality services at reasonable prices, there will be a decline of rail passenger transport (as well as bus services), and an increase in personal car use.

Socio-culture factors. These factors mainly affect the development of passenger rail transport and can be classified as follows (Hornak et al., 2015):

- Demographics (e.g. age structure of population, households, aging index)
- Labor mobility (the effect of increasing the distance of commuting to / from work)
- Lifestyle changes (e.g. the relationship between work and leisure time, use of leisure time)
- Regional disparities (time effect uniformity in passenger traffic at the end and beginning of the week)
- Migration (creating social ties with the migrants' countries of origin increases demand for passenger transport) etc.

Technical and technological factors determine the level of travel and the use of rail freight. These factors include the development of new vehicles, the state of transport infrastructure (the construction of motorways, modernization of railway infrastructure), implementation of the technical specifications for interoperability and construction of intermodal terminals, changes in information technology, and the existence of intelligent transport systems.

Legal. The basic legislative conditions for railway construction, operation of railway infrastructure, operation of transport on railway infrastructure, as well as the rights and obligations of the natural and legal entities related to these activities are stipulated by the Act on railways and its implementing decree (Network Statement ZSR, 2015):

- Act of the National Council of the Slovak Republic No 513/2009 Coll. on Railways and on amendment and completion of certain acts as amended by later regulations (hereafter called the "Act on Railways")
- Act of the National Council of the Slovak Republic No 514/2009 Coll. on Railway Transportation as amended by later regulations (hereafter the "Act on Railway Transportation")
- Act of the National Council of the Slovak Republic No 258/1993 Coll. on the ŽSR as amended by later regulations
- Decree of the Ministry of Transport, Posts and Telecommunications of the Slovak Republic No. 351/2010 on Railways Traffic Order as amended by later regulations
- Decree of the Ministry of Transport, Posts and Telecommunications No.205/2010 Coll. on Determined Technical Appliances and Determined Activities and Activities on Determined Technical Appliances
- Decree of the Railway Regulatory Authority No. 3/2010 of 2 December 2010, setting the charges for the access to railway infrastructure
- Decree of the Ministry of Transport, Posts and Telecommunications No.245/2010 Coll. on expert competences, physical and mental competences of persons in railway operations and transport on railway as amended by later regulations
- Decree of the Railway Regulatory Authority No. 2/2010 of 18 August 2010 on the regulatory framework for laying down charges for the access to railway infrastructure
- Decree of the Railway Regulatory Authority No. 7/2012 of 24 May 2012; by which the Decree of the Railway Regulatory Authority No. 3/2010 of 2 December 2010 setting the charges for the access to railway infrastructure is being amended.

2.2.2. Porter's five forces analysis

The analysis of the competitive environment should be initially focused on the overall transport market, where the main competitors are road freight and individual motoring. In the freight market, not only should the main competitors and freight traffic volume be analyzed,, but also a comparative analysis should be carried out of the development of legislative, economic and transport performance of road freight transport. In passenger transport, households should be analyzed (e.g. the method category of households), as well as the quality requirements of passengers on public mass passenger transport. Then we can proceed to analyze the various forces affecting the competitive environment in the context of rail transport.

Competition in the sector. Competition in the rail transport market began with European rail reform, which consisted initially of the vertical separation of the infrastructure manager and the operation of train services, and later with the horizontal separation of rail passenger and freight traffic, allowing entry of competing carriers (Tomes et al., 2016). In the Slovak Republic, the rail freight market was fully liberalized on 1 January 2007; the market for international rail passenger services has been fully open since 1 January 2010; national markets for rail passenger services in some European countries are still closed.

In Slovakia, there has been an increased number of private railway companies that are licensed to operate a service on track since the liberalization of the rail transport market. Currently, more than 40 companies are licensed, but not all provide rail services. Their share of the rail transport market has varied. The largest share of freight transport is ZSSK CARGO, corp. and for passenger transport Železničná Spoločnosť Slovensko, founded and wholly owned by the Slovak Republic. The rights of the State as a shareholder by the Ministry of Transport, Construction and Regional Development Infrastructure manager – Železnice Slovenskej republiky has a specific position: it is a natural monopoly.

Potential new competitors may be newly created companies or companies that are currently implementing a different mode of transport. In the past, a major barrier to the entry of new competition on the market was high capital intensity (i.e. the purchase of rolling stock, and high fees for licensing). Currently, established companies have a business advantage over new ones, especially in the field of training (e.g. know-how of managers, as well as operational staff), participation in international railway institutions and organizations, in building a network of information and customer centers, and in the use of information systems, with certain modules directly linked to information systems and infrastructure managers.

Suppliers. The rail market is specific in suppliers. The main supplier for companies providing transport services is the infrastructure manager. The infrastructure manager is responsible for the quality and safe infrastructure, affecting the quality of rail service operators (Kendra et al., 2012). The technical - technological part of the railway infrastructure must also be analyzed, as well as current and future charges for its use. Prices for access to the railway infrastructure in Slovakia are regulated and are determined by Decree No.2/2010 Office for railway transport regulation.

Customers. In the rail freight market, customers have a great bargaining position, because it is most often the companies that buy transport service operators on a large scale. At present, a number of railway companies is dependent on a few customers. In passenger transport there is the main customer state that orders transport performance on the basis of the contract of transport services in the public interest. The exceptions are the commercial trains of other operators of passenger transport.

Substitutes. A substitute is defined as: "a product or service that can replace the original product or service because they satisfy similar needs. Usually comes from a different industry than the original" (Slávik, 2005). Considering this definition, there are no substitutes in the transport market. In the event that we will be guided only by the railway market, rail freight services are the most commonly substituted by road and inland waterways; in the case of rail passenger transport, the principal substitutes are cars and airplanes.

The task of controlling is to obtain available information from the company environment, to compile reports on the development of the most important indicators, and to try to anticipate developments that could severely affect the railway undertaking.

2.2.3. Potential analysis

There must be a careful analysis of the various functional areas of the rail company at the beginning of the potential analysis; in particular management, operation, rail vehicles, energetics, business and services, finance and accounting, logistics, personal sources and information systems (Cerna and Masek, 2015). A list of successes, failures and their reasons in these areas can be compiled. There is a need to differentiate between internal and external causes. Figure 1 shows an example of this analysis for the conditions of rail companies.

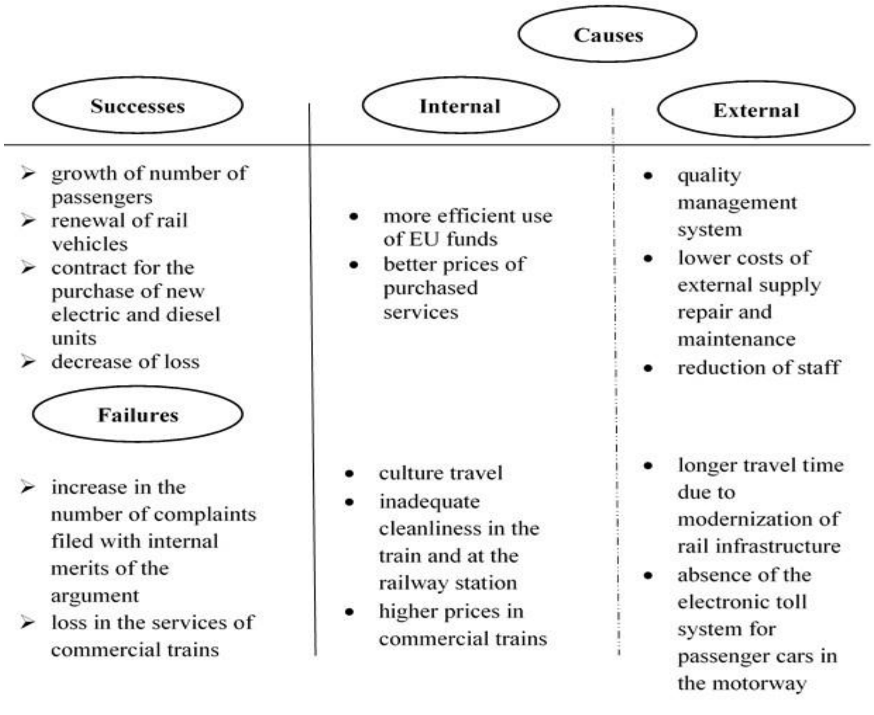

Fig. 1.
Examples of potential analysis in a rail company
Source: Authors

For success, the railway companies must follow a critical approach to their analysis and to avoid subjective evaluation. A good tool is the use of data from management information systems and the empirical results from market research.

2.2.4. Strategic Balance

Strategic balance should provide a comprehensive image of the dependence of a company for different stakeholders. Railway companies should study the dependence of stakeholders on Owner (investor), Staffs, Costumers, Suppliers and The state. Table 1 gives examples of active and passive dependence on the individual stakeholders for rail transport.

Table 1
Strategic balance in rail transport

Stakeholder	Active dependence	Passive dependence
Owner (Investor)	▪ main source of income for the owner ▪ goodwill of company ▪ possibility of obtaining funds from EU	▪ dependency on state funding (subsidies) ▪ difficulties in obtaining commercial loans
Staff	▪ low staff turnover ▪ adequate level of wages compared to the average national wage ▪ possibility of career growth	▪ high specialization ▪ lack of qualified workers for certain jobs
Costumers	▪ natural monopoly (infrastructure manager) ▪ meeting delivery times ▪ supply of additional services ▪ ownership of modern means of transport ▪ supply of other services in the train	▪ a few major customers ▪ no direct customer contact ▪ financial problems of major customers ▪ strong connection to customer logistics processes
Suppliers	▪ one of the main customer suppliers ▪ possibility of leasing vehicles ▪ regulated charges for the use of railway infrastructure	▪ sole supplier (infrastructure manager) ▪ problems with interoperability in international railway transport
State	▪ high number of employees ▪ obligations of the state to ensure conditions for sustainable mobility ▪ transport serviceability	▪ necessary infrastructure ▪ modernization of railway infrastructure ▪ legal framework conditions ▪ number of qualified graduates from secondary schools and universities

Source: Authors

Points are assigned to each interest group by establishing a list of active and passive dependencies; identifying the points scale and the actual allocation of points to the different stakeholders is subjective in nature. The point scale is most often chosen from 0–10, or a percentage from 0–100%. The higher the dependence on the interest group, the higher the point evaluation. It is necessary to use the difference between the maximum potential and the actual value in counting the points of passive dependency.
Strategic balance shows a free area for company meetings. Sufficient scope for negotiation occurs when the sum of points of strategic balance is greater than half the maximum possible number of points. In the case of a high number of points, it is important to focus on strategic bottlenecks, i.e. those stakeholders that have high passive dependence.

2.2.5. Strategy Business Unit analysis

In rail companies it is appropriate to use GE/McKinsey Matrix methods for the realization of Strategy Business Unit analysis. Market attractiveness can be quantified by the following factors:

- Transport market size/ Rail transport market size
- Market growth rate
- Profitability
- Price stability
- Stability of sale
- Capital intensity
- Bargaining position of suppliers and costumers
- Competition
- Legal framework
- Technology.

The following factors determine the competitive advantages of a business unit in railway transport:

- Share of the transport market/rail transport market
- Development of share in the transport market
- Delivery times
- Safety
- Information about deliveries

- Additional services
- Unit value (€ per net tonne kilometer)
- Costs per gross/net tonne kilometer
- Level of marketing.

The possibilities of factor evaluation are described in Section 2.1. In view of the fact that evaluation is subjective, it should be realized by a greater number of controllers, in order to decrease the risk of a higher number of points when they are inadequate.

3. Results

The single use of methods of general strategy analysis is not possible in rail companies. Moreover, it is important to evaluate factors correctly in the individual methods. Inadequate application and evaluation can cause the formation of incorrect strategy, leading to unused potential in the company, and possibly even its eventual disappearance. The GE/McKinsey Matrix was validated on a model example. Tables 2 and 3 show the evaluation results for companies providing services in rail freight transport.

Table 2
Evaluation of market attractiveness of strategy business unit in rail freight transport

Factor	Commodity A			Commodity B		
	Weight of factor [%]	Evaluation of attractiveness [%]	Total evaluation [%]	Weight of factor [%]	Evaluation of attractiveness [%]	Total evaluation [%]
Transport market size	10	39	3.90	16	74	11.84
Market growth rate	3	45	1.35	9	62	5.58
Profitability	12	63	7.56	8	49	3.92
Price stability	4	28	1.12	3	39	1.17
Stability of sale	6	42	2.52	5	24	1.20
Capital intensity	13	33	4.29	9	82	7.38
Bargaining position of suppliers	16	29	4.64	12	73	8.76
Bargaining position of costumers	7	21	1.47	11	58	6.38
Competition	5	36	1.80	13	52	6.76
Legal framework	11	42	4.62	6	89	5.34
Technology	13	58	7.54	8	92	7.36
Total	100	x	**43.81**	100	x	**65.69**

Source: Authors

We realized this evaluation for two commodities. Commodity A represented goods traffic under specific conditions, while commodity B represented traffic of a classical wagon consignment in a through train.

Table 3
Evaluation of competitive advantages of strategy business unit in rail freight transport

Factor	Commodity A			Commodity B		
	Weight of factor [%]	Evaluation of performance [%]	Total evaluation [%]	Weight of factor [%]	Evaluation of performance [%]	Total evaluation [%]
Share on the transport market	7	36	2.52	13	33	4.29
Development of share on transport the market	4	51	2.04	12	54	6.48
Delivery times	17	77	13.09	11	42	4.62
Safety	24	93	22.32	6	75	4.50
Information about deliveries	13	89	11.57	7	90	6.30
Additional services	18	62	11.16	5	61	3.05
Unit value (€ per net tonne kilometer)	9	72	6.48	18	49	8.82
Costs per gross/net tonne kilometer	3	56	1.68	15	64	9.60
Level of marketing	5	36	1.80	13	53	6.89
Total	100	x	**72.66**	100	x	**54.55**

Source: Authors

The application of the GE/McKinsey Matrix showed that commodity A was in the green field, which it means that it is an advantageous position, and that the company should continue to develop this strategic business unit. Commodity B

was in the yellow field, where the company must decide if it keeps developing this strategic business unit. In view of the fact that the evaluation of the market attractiveness of commodity B was higher (Table 2), it should be possible to realize the investment strategy with a view towards increasing income of condition transport market growth.
The results showed that the evaluation must be realized precisely and preferably objectively (although the weight of factors is determined by a team of company controllers or managers). If the weight of the factors “profitability” and “technology” were changed for commodity A (other conditions: *ceteris paribus*), this commodity would turn from the green to the yellow field of the GE/McKinsey Matrix.

4. Conclusions

Strategic business management is the fundamental element to successful businesses in the global economy. The basic task of strategic management is to estimate future trends and to formulate strategic aims based on the synthesis of available information and knowledge about the business, in order to achieve competitive advantages and long-term prosperity. Strategic controlling should perform many tasks, mainly informational, analytical and coordination in the control, creation and implementation phases. The strategic controlling role is increasing continually in today’s global and rapidly changing economic and social conditions. The activity of controlling is very important in railway transport, which is characterized by specific conditions for providing rail services. It is very important that the controllers in rail companies know the methods for realizing relevant strategy analysis in detail. The methods proposed here are effective tools for the implementation of strategic analysis, allowing the managers to develop good strategies. Those railway companies with a well-developed strategy can provide rail services on the transport market in the long term, therefore increasing the competitiveness of rail transport, and reducing the environmental burden.

APPLICATION OF NDT TO RAILWAY TRACK INSPECTION

Cafiso Salvatore[1], Capace Brunella[2], D'Agostino Carmelo[3], Delfino Emanuele[4], Di Graziano Alessandro[5]

[1,2,3,4,5] *University of Catania, Department of Civil Engineering & Architecture, via Santa Sofia, 64, 95125 Catania, Italy*

Abstract: Track failures are one of the main problems that railroads have faced since the earliest days is the prevention of service. The lack of a systematic monitoring brings to the impossibility to produce an effective long term railway track management system, by allocating budget where emergencies come. Latest technology can improve the rail inspection with higher cost of the equipment. The great advantage is related to the speed and precision of the measurement, avoiding to interfere with the normal use of the infrastructure. Despite that, in local railway with reduced gauge, the use of traditional monitoring systems at high speed is not feasible. In this framework the monitoring of the track with alternative non-destructive techniques (NDT), such as GPR and LWD are promising for ballast and track stiffness inspections. In recent decades, these devices have already proven their effectiveness in the field of road pavement engineering and prospects are the same in the rail sector which is increasingly growing. This paper details, with a trial on a site of investigation, the opportune and effective use of the equipment and their performance. As future work the use of NDTs is expected to affectively contribute to a creation of a reliable monitoring system for preventive maintenance strategies of railway asset and Quality Control of track works, as well.

Keywords: NDT, ground penetrating radar, light weight deflectometer, rail track, ballast.

1. Introduction

Railway lines are investments with very long life. Today many tracks are over 100 years old. Of course components and mainly rolling stock have been exchanged during the years, but parts of the track might remain the same – especially the track structure and formation. Typical lifetimes of for rails are 30 – 60 years and turnouts 20 – 30 years (H. Sundquist, Byggande, 2000). There is a clear trend towards higher speeds and higher capacity (more trains on the tracks and heavier trains). Nowadays more trains occupy the track and the competition with other means of transportation becomes harder. To face the new circumstances, more effort has to be put on track maintenance and construction QC&QA to ensure the issues of safety, comfort, serviceability and economy. Moreover, there is also a trend towards decreased time for maintenance and decreased funds for maintenance.

This could be done with the help of measurements of important parameters which are analyzed to give knowledge about the condition of the track and, with increased traffic and more frequent failures on railroads, rail inspection is more important today than it has ever been (C. NDT, 2013). Although the focus of the inspection seems like a fairly well-defined piece of steel, the testing variables present are significant and make the inspection process challenging. To keep railroads safe and prevent any high maintenance costs caused by failures on the railroads, scheduled inspections must be performed on rail tracks and soil.

Soil inspection investigates the Ballast, Subgrade, and Roadway (BSR) component, which includes all earthen materials on the track structure, tracks, and embankments (Uzarski et al., 1993). It focuses on the thickness of the ballast, subsoil material and geotechnical properties of subgrade. Traditionally, the inspection is executed mainly by digging trenches at evenly spaced intervals and in locations of special interest (Hugenschmid, 1999). Soil inspection also investigates the plants on the railroads (Eriksen et al. (2004). Latest technology can improve the rail inspection with higher cost of the equipment (Cerniglia et al., 2006). Those technologies are mainly developed directly from the railway Agency to monitor their network. The great advantage is related to the speed and precision of the measurement, avoiding to interfere with the normal use of the infrastructure.

Generally local railways have not the most advanced equipment to survey the network as well as the economic possibility for a systematic global survey. The result is that the maintenance is carried out to avoid track failures with visual and manual inspection of the track based on the experience of the technicians. Unfortunately, the lack of a systematic control and the economic difficulties, especially in local railway track lead to the impossibility of producing a long-term effective track management system. In this framework, in order to carry out soil and track inspections, for reliable preventive maintenance strategies and QC of construction works, literatures studies and practical applications conducted with Ground Penetrating Radar (GPR) and Light Weight Deflectometer (LWD) are promising for a success fully non-destructive tests.

This paper details with a trial on a site the use of GPR and LWD and their performance.

2. Ground Penetrating Radar (GPR)

The ground penetrating radar is a geophysical radar system with antennas and receivers used to perform non-destructive investigations of under-ground characteristics with high resolution and in depth (up to 3.2 m from the surface).

GPR operation principle is based on electromagnetic theory, its functioning consists in sending short electromagnetic pulses into a medium and when pulses achieve an interface they are reflected back partially and collected by the receiving antenna. The reflected energy is displayed in wave-forms and the greatest amplitudes represent the interfaces

[1] Corresponding author: dcafiso@dica.unict.it

between layers with distinct dielectric characteristics (Daniels, 2004). Ultimately, GPR measures the travel time between the transmission of the energy pulses and its reception. The collected data are processed and saved on a control unit, that is also used to generate the necessary pulses for the operation of the antennas.
The track substructure, consisting of the ballast, sub ballast, and subgrade layers, has a profound influence on track performance. The substructure performance is significantly affected by moisture accumulation and thickness of the roadbed layers (Selig & Waters, 1994). Accurate knowledge of the substructure condition is important in effectively assessing the potential for service interruptions and the need for slow orders.
In this field, the GPR seems to be a good alternative to traditional core inspection techniques. Methods of applying GPR to railways are being developed to provide a continuous evaluation of the track substructure conditions relative to subsurface layering, material type, moisture content and density.
As mentioned GPR can provide a fast, nondestructive measurement technique for evaluating railway track substructure condition (Olhoeft & Selig, 2002; Selig et al. 2003).
Main application of GPR in railway track are:

- Monitoring the condition of railway ballast, and detect zones of clay fouling leading to track instability,
- Mapping soil, rock or fill layers in geological and geotechnical investigations, or for foundation design.

In Germany, Göbel et al. (1994) referred by Saarenketo performed GPR tests for determining: ballast thickness, layers interfaces, ballast pockets and mudholes location.
Jack and Jackson (1999) studied ballast layer along a track using two antennas with different frequencies, they found: clearer ballast interfaces indicating a clean ballast and thickness variations, affirmed GPR as a useful tool for identifying track sections with urgent necessity of rehabilitation.
Gallagher et al. (1999) found positive results for survey of ballast/subgrade interface, such as anomalies detection. Hugenschmidt (2000) reports a study developed on different alignments, evaluating the ballast thickness, fouled zones and ballast/subgrade interface depth. The conclusion was that radar survey is useful combined with traditional inspection methods. Recently, to determine the correlation between water content or fouling of a rail-road track and GPR signals, a full-scale railway track model was designed and constructed at the University of Massachusetts Amherst (Hamed et al. 2016). Different models were tested with moisture content conditions of dry, saturated and two points between these extremes. 450 MHz and 2 GHz frequency antennas were used to evaluate the different conditions. The results showed that the dielectric permittivity and frequency spectrum can be used as an indicator of fouling percentage and moisture content in a track.

3. Light Weight Deflectometer (LWD)

The light weight deflectometer (LWD) (Figure 1), is a hand portable device that was firstly developed in Germany to measure the soil in situ dynamic modulus. The LWD consists of a circular plate (150, 200, 300 mm diameter) loaded by a falling mass (10 - 15 - 20 kg).

Fig. 1.
Light Weight Deflectometer

The load resulting from the drop is dampen by a series of buffers, producing a transient force, dynamic in nature, simulating the effect of a moving vehicles. During the time interval of the load application, load and deflection time histories are recorded. The LWD, used for the trial test, was equipped with one geophone positioned in the center of the plate and 2 additional geophones that can be used for specific measures outside the plate.
When applied directly on the subgrade, data processing from LWD test is carried out according to Boussinesq theory for the estimation of the Elastic Modulus E by the following expression:

$$E = \frac{f \cdot \left(1 - \nu^2\right) \cdot \sigma_0 \cdot a}{d_0} \tag{1}$$

Where; f: the plate rigidity factor, a: is the load plate radius, r_0 and d_0 : respectively the peak values of the applied stress and the measured deflection under the center of the plate, ν: is the Poisson's ratio.

The influence of soil depth of LWD tests is considered to be 1÷1.5 diameters of the plate.
Neupan et al. (2016) from the university of Kansas estimated with LWD the resilient modulus of the substructure considering different combination of fouled ballast (10-40% by weight) and moisture content (1-10%). The test was conducted by reproducing in laboratory the real condition. Considering the various combination, they concluded that moisture content has the highest influence in reducing the bearing capacity.
Horníček et al (2014) used the LWD for the long-term evaluation of the condition of trial sections with the application of under-ballast geocomposites useful to avoid long-term problems of the track geometric position caused by the pushing of fine-grained soil from the subballast into the ballast bed (so-called pumping effect) and by the missing base layer between the ballast and the subgrade.
The exploitation potential of the Lightweight Falling Deflectometer is still increasing, and the results are aptly combined with other analytical and mathematical methods (Fernandes, et al., 2012; Burrow et al, 2007). In some cases, the impact device is used for a specific assessment of spots with problems resulting from the unstable geometric track position (Sharpe & Govan, 2014).

4. Case study

The trial site chosen for the trial run of the equipment is part of the Circumetnea railway track. Circumetenea manage about 120 km of local railway track in Sicily, by circumnavigating Etna volcano. The track is characterized by restricted gauge (950 mm instead the 1435 mm of the European standard) and a different composition of the superstructure which is going to be modernized with new concrete sleepers, new fasting system and the tamping of ballast. The area selected for testing is close to the Adrano nord railway station. It has the different conditions of tamped and not tamped ballast, wooden and concrete sleepers and cribs full with ballast or a complete lack of ballast in cribs.
The test was conducted on about 290 m of railway line. Specifically, the trial was conducted on three different sites:

- Site A: ballast with partial renovation and tamping,
- Site B: ballast in bad conditions,
- Site C: ballast recently replaced.

Thanks to this variety it was possible to test different railway track composition to test the ability of the equipment to catch the possible differences in: ballast layer thicknesses and their changes along the line (based on the presence of tamped ballast or old ballast), difference material for the sleepers, lack of presence of ballast in the cribs, different stiffness of the substructure based on the sleepers and ballast conditions. In the present experimental research work, an operative description of the equipment for the railway tests is presented. Preliminary results are used to draw potential field of application to provide a framework about the use of the equipment for railway track monitoring.

4.1. GPR test

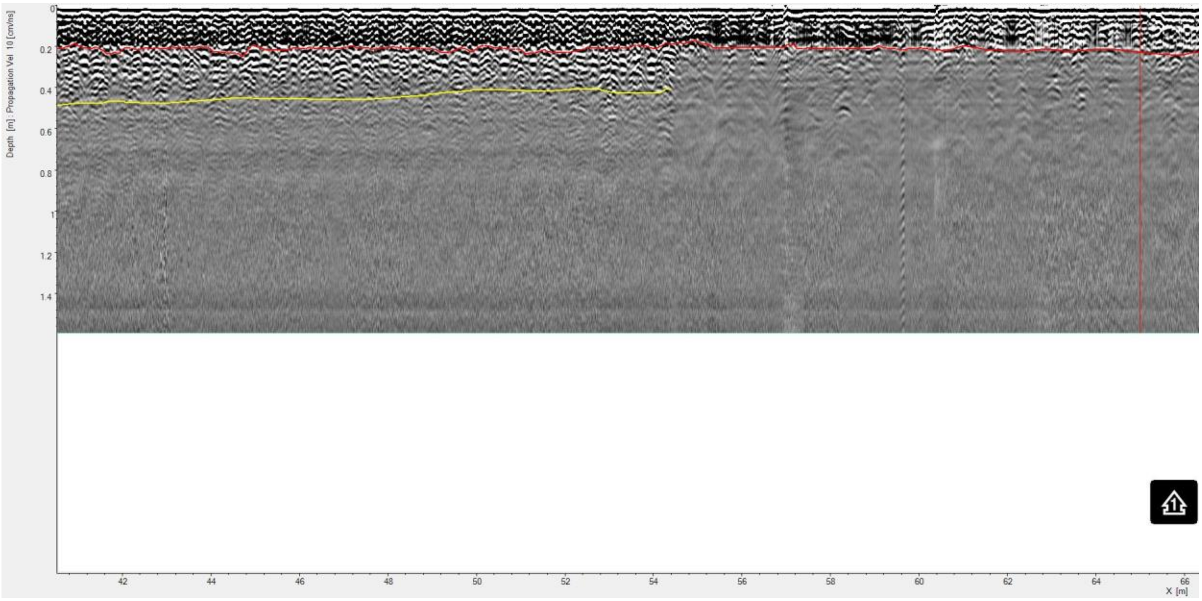
The GPR used in the trial, is a ground radar composed by two antennas of 600 MHz and 2GHz frequency. The wheel system was adapted for the test by modifying the wheels and the DMI configuration from road to railway application. Wheels are built with cone shape and made with resin for running on the railway track and avoiding electrical interferences. The chassis was adapted to the ground technology positioning the antennas very close to the surface of ballast (e.g. less than 10 cm) (Figure 2). In this configuration it was easy pushing the cart at a walking speed, but the system should be able to work at a speed up to 30 km/h.

Fig. 2.
Ground Penetrating Radar adapted for rail inspection (Site A)

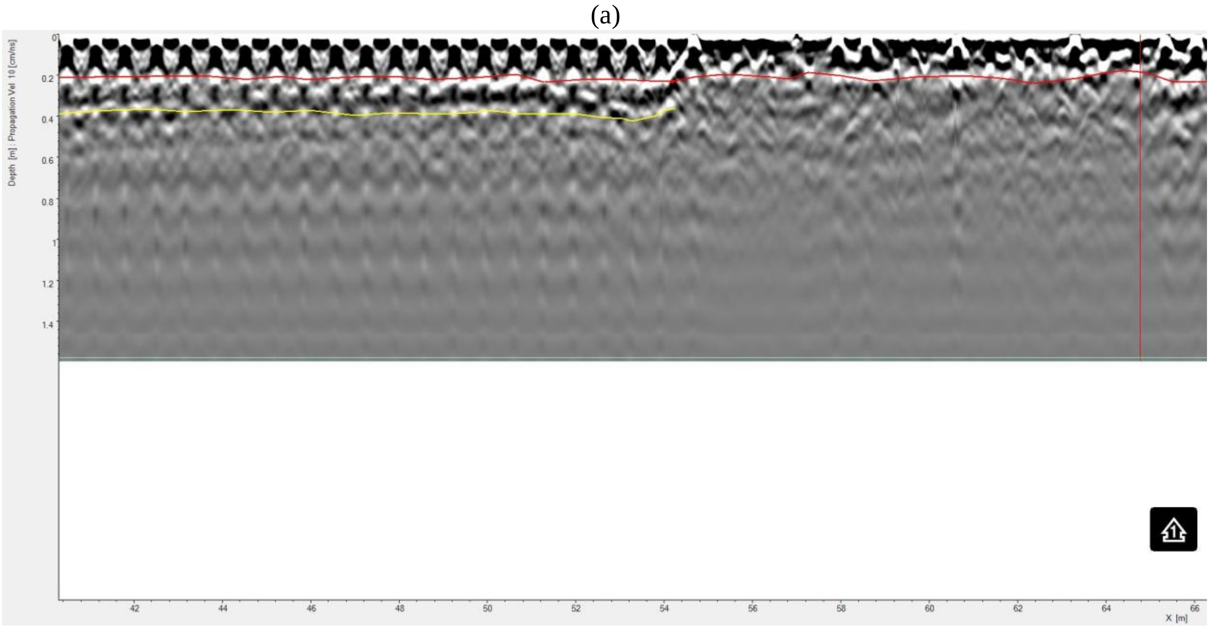
An example of radargrams collected by the two antennas is reported below. Fig. 3. reports the image of the radargram and the identification of the ballast layers.
To obtain this image the filters applied to radar map are:

- Identification of “zero point”, i.e.the transition air/ground. This operation is mainly used when scans are performed with antennas not in contact with the surface,
- Background removal: This command applies the Clear-X filtering algorithm used to remove continuous components along the X axis (horizontal direction) following user preset parameters, Depth min [m]=0 and Depth max [m]=10,
- Bandpass filter: this command applies a filter onto a frequency interval,
- Linear gain: is used to apply a filtering algorithm of the power equalization along a sweep to a selected radar map on the basis of an estimated linear attenuation.

The red line in the radargrams of Fig. 5 shows the transition from the tamped ballast characterized by a clear signal indicative of the contrast in dielectric constant from the ballast/subgrade interface, and the transition between the renewed ballast in site A (left) and the old railway track of site B (right).



(a)



(b)

Fig. 3.
Radar scans of the trial test with 2GHz (a) and 600MHz (b)

The presence of layers’ interfaces at different depths was detected by 600 and 2000 MHz antennas, as well.
As expected 2000 MHz is more effective in identifying layer’s interface at shallower depths that in this ballast application resulted limited at about 40 cm.
To identify deeper interfaces (e.g. ballast fouling), sub-ballast and subgrade moisture conditions the 600 MHz antenna resulted effective up to a depth of 1.5 m.

Also it's clear the signal different between the wooden and concrete sleepers. The wooden sleepers give a greater dispersion of the signal.
A comparison of the layer depths detected by the two antennas pointed out a Normalized Root Mean Square Error (NRMSE) of 20% when the 600 MHz antenna is used for the surface interlayer (absolute RMSE=0.05 m) and NRMS=31% when the 2GHz antennas is use to detect the layer at about 50 cm depth (absolute RMSE=0.16 m).

4.2. LWD test

LWD was used to estimate the stiffness of track foundation and sleeper support, as well. Tests were carried out positioning the loading plate in the middle of the sleeper and directly on the ballast between sleepers (crib position) and at the side of rail (Figure 4).

Fig. 4.
LWD test with plate in crib position (Site A) – LWD test with plate on the sleeper with additional geophones (Site A)

Results of drops on the sleeper, reported in Figure 5, show a clear variability in the measured deflections among the sites with different ballast conditions. Site with ballast of good quality (site C) reports lower deflections and higher uniformity.

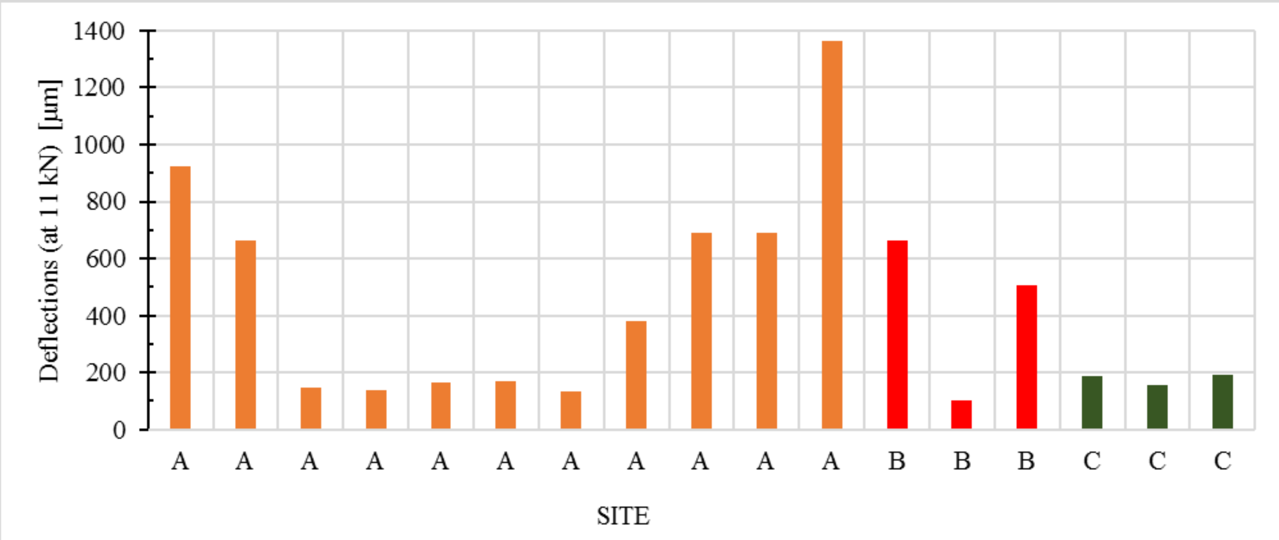


Fig.5.
Light Weight Deflectometer results

Deflection and load data can be used to calculate the track modulus. The track modulus, u, is defined as the applied force per unit length of rail per unit deflection (δ) (unit Pa) (Selig et al., 1994):

$$u = {}^{q}\!/_{\delta} \tag{2}$$

Where; *q*: the vertical foundation supporting force per unit length.
When the load is applied at the center of the sleeper, a simplified model of uniform vertical foundation supporting force per unit length can be assumed. This assumption is sustained by the uniform deflection of the sleeper detected during the test. The comparison of center plate deflection (Df1) with deflections measured at 20 (Def2) and 30 cm (Def3) (Figure 6) shows a negligible sleeper rotation is detected (i.e. 0.01% on average).

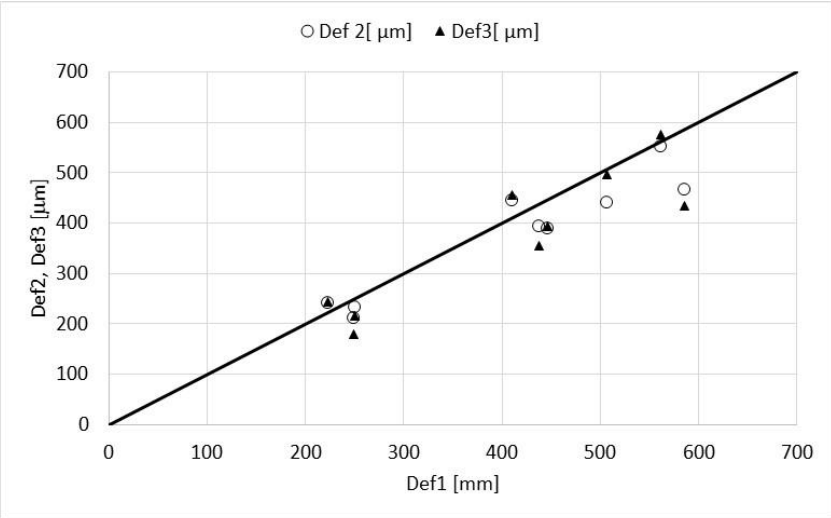

Fig. 6.
Deflection at the center of the loading plate (Def1) vs. deflections at 20 (Def2) and 30 cm (Def3) (load 11 kN)

Under this hypothesis, the track modulus can be derived from eq. 2 by using data of LWD test.
Track modulus was compared with ballast modulus estimated by Equation 1 with LWD test carried out directly on the ballast surface.
Results reported in Figure 7, pointed out how variability in ballast modulus is not necessarily reflected in the track modulus due to the interaction between rail, sleeper and ballast. Further, the sleepers may also have voids beneath them, which lead to large deflections with low loads (Sussmann et al., 2001).

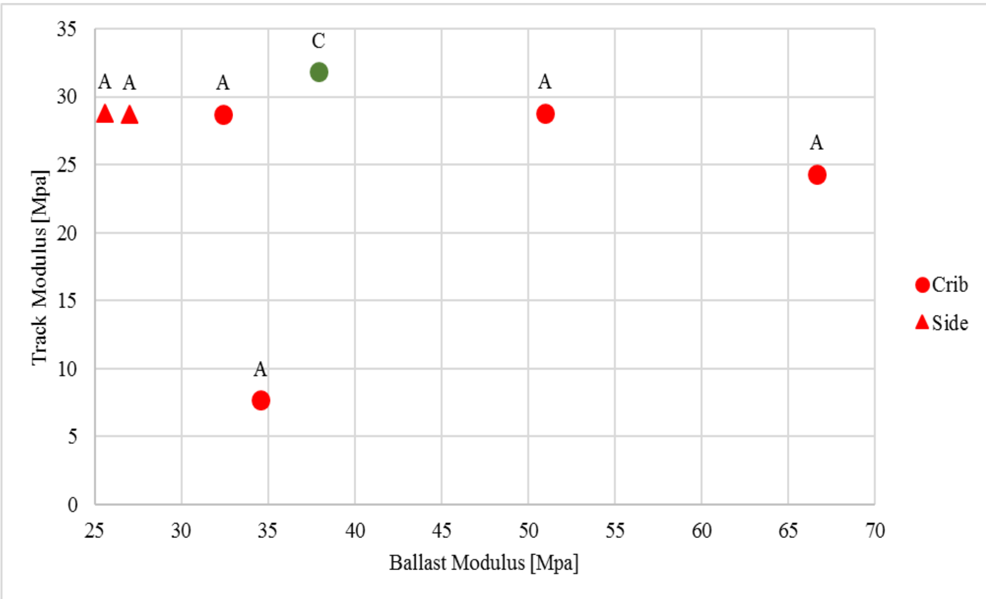

Fig. 7.
Ballast Modulus vs. Track modulus. Crib and Side positions. Sites A and C.

5. Lessons Learned and Conclusion

The main railway lines are by now monitored with high efficiency equipment based on the most advanced technologies in the field. In the case of local railway, which are not part of the main network, monitoring is still challenging in terms of costs and maintenance needs. Furthermore, a lack of a systematic monitoring brings to the impossibility to produce an effective long term track management system, by allocating budget where emergencies come. The present paper has explored promising solutions to overcome this limitation by using the equipment well known for road pavement monitoring, but not yet diffused in the railway management. Particularly the paper focused on the adaptation needed to use GPR and LWD on a railway track to test the bearing capacity and quality of ballast and track geometry. More specifically, the field tests were carried out on a local railway with reduced gauge of 950 mm. That condition gave the opportunity to test the equipment in an environment open to the introduction of such system in rail track monitoring for maintenance and Quality Control, as well

LWD showed its ability to identify variability in track stiffness. One requirement for stable track is a relatively uniform track stiffness that can support the applied vehicle loads. Track at locations where there are changes in track stiffness are hypothesized to result in accelerated track condition deterioration.
However, LWD is able to apply maximum loads of about 10 kN. At that limited load, deflection is mainly related to seating of the sleeper on the ballast. The seating deflection is defined as the deflection of the track under the light seating load, and the contact deflection is defined as the additional deflection that occurs from the seating load to the full load. In this way, the presence of void can be detected by variation of track stiffness at low loads.
The void deflection, is an indication of the slack in the track. Common reasons for high or variable void deflection are poor sleeper-to-rail fastener condition or the presence of fouled ballast, resulting in hanging ties.
Diagnosis of a track problem can be improved by implementing systems that measure the change in deflection of the track between two distinct, loads. For example, to eliminate the effect of voiding the secant stiffness may be calculated between 10 and 70 kN (axle load of 20 – 140 kN) (Eurobalt II). In the framework of the present paper, LWD may be used to reach the highest load-carrying capacity.
The main disadvantages of GPR systems in railway application are similar to the road one, because interpretation of radargrams is generally non-intuitive and considerable expertise is necessary to effectively design, conduct, and interpret GPR surveys.
By using a dual frequency system, the best of both is achieved, on this particular sites, the 2000Mhz provided high resolution data to approximately 0.4m depth, while 600Mhz provides greater depth penetration up to 1.5 m. These penetration depths are less than available in road applications due to the interferences produced by the sleepers at the top of the ballast surface.

Acknowledgements

LWD and GPR were acquired by the University of Catania in the framework of the Regional RESET project, funded by the Sicily Region Authority. The authors wish to express their gratitude also to “Ferrovia Circumetnea” for making available the railway sites.

INVESTIGATING THE INFLUNCE OF LONGITUDINAL GRADIENTS ON THE MECHANICAL BEHAVIOR OF FASTENING SYSTEMS OF RAILWAY TURNOUTS

Ahmed Abdelmoamen Khalil[1], Kamal Ghamry Metwally[2]
[1] *Benha University, Faculty of Engineering at Shoubra, Egypt*
[2] *Beni-Suef University, Faculty of Engineering, Egypt*

Abstract: The research presented in this paper aims to determine the influence of longitudinal gradients on the behavior of fastening systems of railway turnouts. This influence will be assessed through a case study in line No.3 of Greater Cairo metro network where 1 in 8 crossover has been installed in 2 % longitudinal slope. It has been observed that severe wear induced in the outer lead rail is out of tolerance in a short period after installation. Thus, the fastener steel clips on that rail have been damaged. Therefore, a sequence of analysis has been carried out in this paper to identify the causes of damaging of the clips. Clip`s material has been tested to determine its chemical composition; then stereoscopic photos of fracture surface of the clip (X8) have been taken. The vertical and transversal wheel loads of the wagons affecting the lead rail fastening system have been simulated using ANSYS software, thus results of the simulation have been analyzed in detail. Finally, a conclusion on the mechanical behavior of turnouts, a recommendation to minimize rail wear and to eliminate clips damaging have been introduced.

Keywords: railways, turnouts, longitudinal gradients, fastening systems, FEM.

1. Introduction

When a vehicle travels around a curve, centrifugal force will act on its center of gravity and forces it outwards. Centrifugal force results in an overturning moment and a stability moment is generated. When the train speed exceeds the balancing speed for the curve, the net result of these moments is to transfer a portion of the wheel load from the inner to the outer rail. The effect would then be to apply a greater load on the outer rail than on the inner. Additional flange force caused by excess, unbalanced centrifugal force would normally have little influence on the total flange force as it is usually considerably less than that portion of the flange thrust due to curving. Unbalanced centrifugal forces, however, can contribute significantly to vehicle rollover tendency, particularly when the speeds exceed the design speed of the curve and/or there is a track defect that results in a sudden increase in cant deficiency (Nilmani, 2012).
(RailCorp, 2011) introduced in a comprehensive study that when installing a crossover on a vertical gradient, the train going down-slope on a physical negative plane will experience a centrifugal force. The train will be constantly riding on the rail on the lower side of the slope or on the curved closure rail. The wheel flange will have a tendency to hit the switch point at the switch entry and the frog point during the wheel transferring at the frog. In addition, as the rail components of special trackwork are not fabricated with an inward rail cant, the down-slope train movement momentum through the crossover track and the train dynamic braking will exert a higher lateral force on the rail head. This could have a serious implication on operational safety, unless the train speed is reduced.
(Avinash Prasad, 2011) presented that turnout is the inherent weaker portion of the track work and thus the most sensitive to improper design, construction and maintenance. If proper design of diverging track of turnout is not done, it will lead to reduced operating speed in order to maintain good ride quality and component life. The diverging route of turnout has lower speed capacity, compared to mainline track. This given situation reduces the high speed potential of railroad vehicle negotiating the turnouts. Avinash stated that near point of switch in diverging track, switch rail creates kink in the alignment. Due to sudden change in direction of alignment, lateral force/acceleration is introduced. Normally turnout diverging lead curve is not provided with transition curve after the switch rail and before the crossing in conventional crossings. The switch rail can be straight as well as curved. If switch rail is straight, the curvature in alignment is only introduced at start and end of the switch rail. If switch rail is curved, then curvature starts at the switch entry point and ends at switch rail end before the closure rail. Normally, there is no provision of transition in switch rail, which leads to unbalance force at entry and exit of the switch rail. Normally turnout diverging lead curve is not provided with transition curve after the switch rail and before the crossing in conventional crossings. This will lead to unbalance forces. Due to lead curve radius, there is centrifugal force acting on the diverging portion of track.
Criteria for locating special trackwork on vertical gradients are system specific. The system operator should determine the criteria based on acceptable cross level difference on the diverging track on special trackwork, and the assessment of vehicle design, trackwork /alignment design, special trackwork design and track supporting structure. Special trackwork should be located on tangent track with 0% grade whenever possible. If it is necessary to locate special trackwork on grade due to track geometric restrictions, the design grade should[2] be as flat as possible. The track support structure for special trackwork located on a vertical gradient greater than 1.5% should consider the use of a direct fixation system to restrain movements contributed by thermal and lateral load phenomena. Special trackwork should have built-in anti-creep devices or be incorporated with a rail anchoring system in the track design to mitigate rail axial load that could change the turnout geometry due to thermal and vehicle dynamic braking. A crossover located on a

[2] Corresponding author: ahmed.khalil@feng.bu.edu.eg

vertical gradient higher than 1.5% is not recommended. 1.5% grade will introduce a cross level deficiency of 2.8 mm, which is approximately equal to the cross level construction tolerance of 2 mm. A crossover located on a grade greater than 1.5% could result in the diverging track becoming operationally unsafe. (Lam, 2010).

Movement on a curve generates wheel–rail double contact at the outer rail (Esveld, 2001; Lichtberger, 2011; Pyrgidis, 2016). This occurs due to the fact that when a train moves on a curve the railway wheelset does not have the freedom to be placed radially. Usually, the front bogie wheelset is displaced toward the outside of the curve. As a result the flange of the outside wheel hits on the inner edge of the outer rail. The generated guidance force forces both of the axle's wheels to slip toward the inside of the track, thereby generating friction forces on both rails. The first point of contact (on the outer rail) lays on the rail surface on which the wheel's tread is rolling, while the second point is the contact point between the wheel flange and the rail. A part of the vertical load is transferred from the wheel to the first point, building up the friction force. On the second contact point the rest of the vertical load and the total transversal force are transferred.

When vehicle speed exceeds the balance speed for the existing cant on a curve, the resulting centrifugal force has two separate effects, a) flange force acting against the outer rail, and b) increased load on the wheel running on the outer rail due to load transfer from the inner wheel. As the speed increases, so does the centrifugal force, and both flange force and wheel load on the outer rail increase together. Actually, centrifugal force acts on the center of gravity of the vehicle body. The body rolls on its suspension, transferring additional load onto the wheels on the outer rail. Wheel climbing is less likely to occur due to increase in centrifugal force provided that the path followed by the wheel is smooth and not interrupted by a track defect. The total change in direction at the entry is made up of the angularity of axle, the switch angle and the increase in switch angle from the theoretical toe of switch to the actual point of attack and is termed as angle of attack (Kumar and Mishra; 2013).

(TCRP; 2012) determined the desirable locations of turnouts and crossings. It was presented that the ideal location for turnouts, crossings and crossovers is in flat and straight sections of track. Also, it was concluded that if special trackworks should be laid in curves, cant, or vertical curves, the ability of the trackwork to perform in a satisfactory manner is compromised. So that, turnouts and crossovers are not placed in difficult locations and the overall requirements for special trackwork are minimized.

This paper focuses on investigating the influence of longitudinal gradients on the behavior of fastening systems of railway turnouts. Thus, analytical modeling and numerical simulation using ANSYS software have been carried out. Also, results of an experimental investigation carried out on a crossover placed in sloped section in Cairo metro tunnel, line 3 are presented.

2. Problem Statement

2.1. Case of Curved Tracks

A railway curve is a track which charges alignment without any sharp corners in rails. This change in alignment through curves is best attained through a circular curve. A circular curve has the advantage of uniform curvature i.e. uniform change of direction which makes the task of management of forces during change of alignment easier. Nature of forces experienced by vehicle is different on curved track as compared to straight tracks (Goel, 2010).

The vehicle passing over the curve continuously changes its direction over a curve. Due to the inertia, the vehicle tends to continue moving in the straight line but the forced change in direction of the movement by track gives rise to lateral acceleration acting outwards which is felt by the vehicle and all passengers inside. This acceleration is called centrifugal acceleration and the force due to the same is called centrifugal force (Chandra and Agarwal, 2007). To counteract the effect of the centrifugal force, the raising of outer rail with respect to inner rail is done. This raising of outer rail is referred to as cant. Due to the vehicle being on slope, a component of weight starts acting towards the lower rail. This component is called centripetal force and it acts opposite to the direction of the centrifugal force. The forces on a vehicle on the curve having cant are shown in Fig. 1.

2.2. Case of Turnouts

In some cases the designer is compelled to set out a turnout or a crossover (two turnouts) to change the direction of train movement to another branch line or to parallel track respectively. In turnouts, the straight and curved branch tracks are laid on same transversal sleepers. Therefore, it is impossible to provide the curved branch track with a cant. Thus, special track works, i.e. turnouts, crossovers …etc, are not provided with cant. Fig. 2 illustrates layout of sleepers in a right turnout.

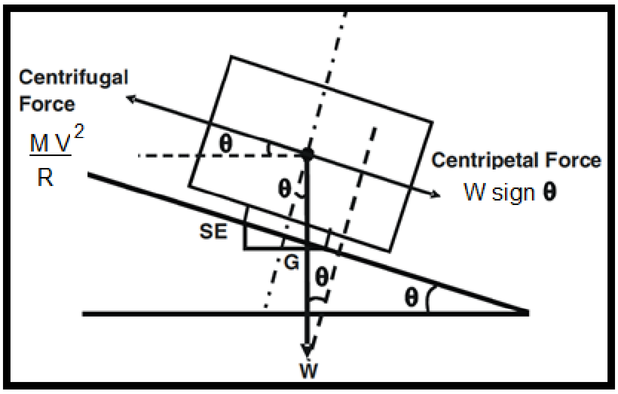

Fig. 1.
Forces Acting on Vehicle Moving on Horizontal Curve with Cant.
Source: Goel. A. (2010), Railway Curves

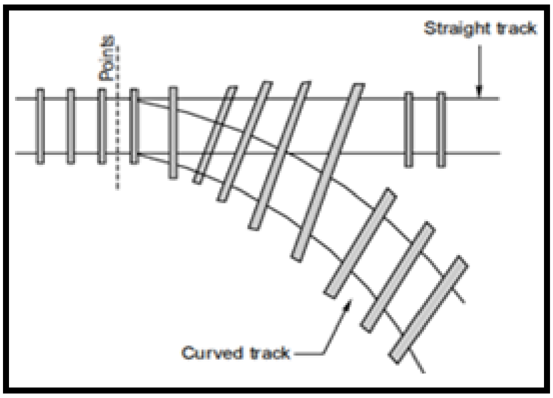

Fig. 2.
Schematic Layout of Sleepers in A right Turnout
Source: Chandra and Agarwal (2007), Railway Engineering

When turnouts are laid on longitudinal gradients, the elevation of the contact point of the train wheel on the outer rail of the diverging branch track will be lower than the elevation of the corresponding contact point on the inner rail. This phenomenon occurs due to precedence of the outer wheel to the inner wheel during running on a curve that is laid on a down gradient (G). It is illustrated from Fig 3 and Fig. 4 that a negative cant (C, i.e. difference in elevations of points 1 and 2) will be produced in turnout A, whereas; a positive cant in turnout B. Fig. 4 shows that point 1 is lower than point 2 and points 2, 3 and 4are at the same level.

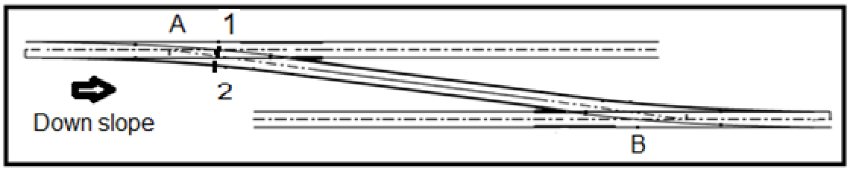

Fig. 3.
Layout of Turnouts (Crossover) on Down Gradient

As a result of running of trains on the down sloped turnout (A), the centripetal force will change its direction to the outer rail as illustrated in Fig. 5. So, the diverging route of turnout could produce high lateral forces and accelerations due to centrifugal and unbalanced forces. Also, there will be a tendency for the wheel to slide towards the lower rail.

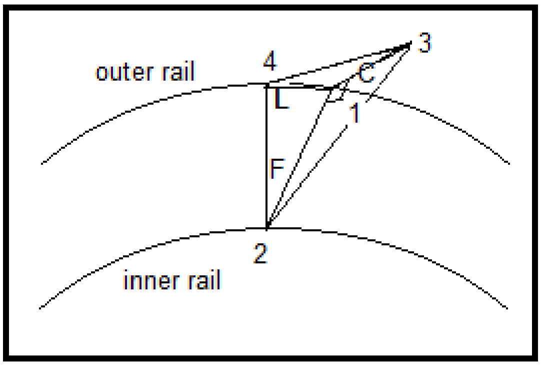

Fig. 4.
Negative Cant Production

The normal deterioration of the track surface, combined with any imperfection in the installation or manufacturing of the rails will compound the effect of the negative cant on the diverging track. In addition to increasing the straining actions and surface defects such as corrugations and wear in the outer rail, these forces impacting negatively on the fastening system as they produces higher induced stresses; so that they may cause damage of clips and screw spikes. K-type fastening system is shown in Fig. 6.

3. Material and Data

3.1. Experimental Works

A stereoscopic investigation on a failed clip; that used in a down sloped turnout inside the tunnel of Greater Cairo Metro; has been carried out in laboratories of the Central Metallurgical Research and Development Institute to determine locations of initiation fracture. Fig. 7 illustrates a stereoscopic photo (X8) for the failed U-shape clip. Also, chemical analysis was carried out by Spectra analytical instrument model ARL 3560. Table 1 represents the chemical composition of 3 sparks and mean value for a sample of the same failed clip.

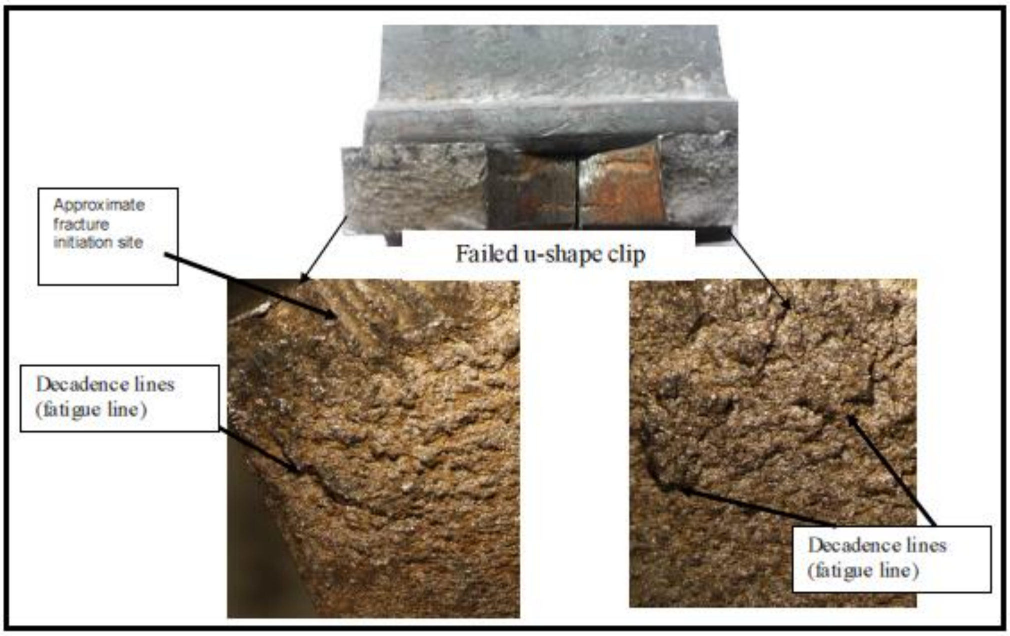

Fig. 7.

3.2. Simulation Works

A nonlinear numerical simulation for the resultant transversal force (H) acting on the outer rail has been carried out using ANSYS software. In this simulation, the vertical load was taken 75 and 120 kN in two different cases. Values of the transversal force were assumed to be increased incrementally in the range from 30 to 70 kN and from 40 to 110 kN for the first and the second cases respectively. The fastening system was simulated by multiple contact elements to achieve the interaction between the different elements. Geometry and meshing of the finite element model are shown in Fig. 8; whereas samples of the simulation output for case of 75 kN vertical load and 30 kN transvers force are shown in Fig. 9 (a), (b) and (c). Material properties of the fastening system were considered as follows:

Density of steel (γ) =78.5 kN/m^3
Elastic modulus (E) =21000 kN/cm^2
Poisson ratio (ρ) =0.30
Modulus of rigidity of steel (G) =8000 kNlcm^2
Rubber pad stiffness =120 kN
Tensile strength of rubber pad =20 MPa

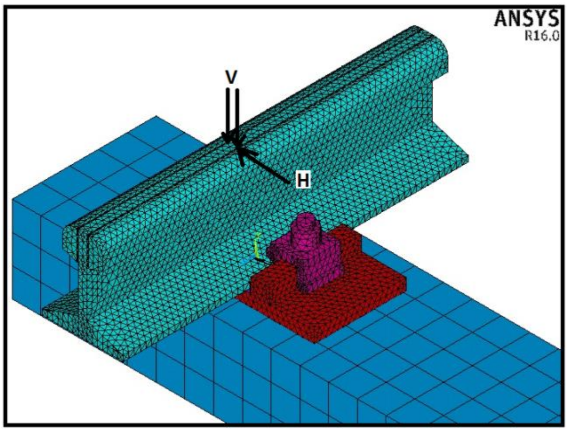

Fig.8.
Finite Element Model

4. Results and Discussion

4.1. Results of the Experimental Work

The chemical composition emphasizes that the material of the sample is structural and constructional steel alloy No. 1.0487. The photos of the crack surfaces show that crack is initiated from the upper surface of the clip and propagated throughout the thickness of the clip. It is also noticed that the cracked surface contains little feature of the decadence lines (fatigue line).

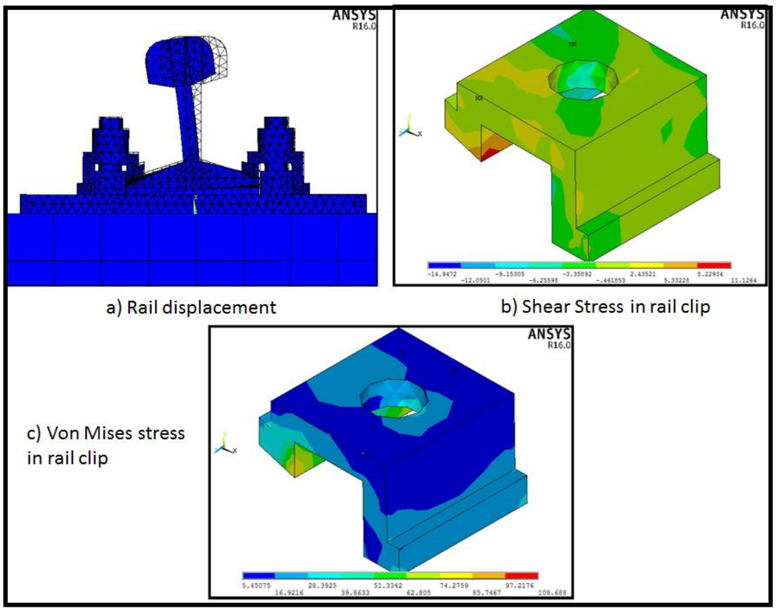

Fig.9.
Samples for Solutions of ANSYS

4.2. Analytical Modeling

Analytical model for the transversal force (H) on the outer rail can be deduced as follows:
Referring to Fig. 4, let the distance between points 1 and 4 = L (mm), negative cant = C (mm), distance between points 1 and 2 = distance between center lines of rails = 1500 mm, angle of axle angularity = < F, and W = Axle weight (kN), v = train speed (km/h) and g = gravity acceleration = 9.81 m/s^2.

$G\% = C/L$

$C = L \times G/100$ mm

$L = 1500 \times \mathrm{Tan} < F$ mm

But, $< F$ = Axle angularity = turnout angle

$C = 1500 \times G/100 \times \tan < F$

$= 15 \times G \times \mathrm{Tan} < F$ ……………………… (1)

Referring to Fig. 5,

Centrifugal force = $M \times v^2/R$

$= (W/g) \times v^2/12.96\ R \quad \text{kN}$

Centripetal force = $W \times \sin\theta = W \times \tan\theta \quad \text{kN}$

Where, $\tan\theta = C/1500$

Transvers friction force = $Y = \mu \times W/2$

Where, μ = transvers coefficient of friction between train wheel and rail.

$\mu = 0.25$

$H = \mu \times W/2 + (W/g) \times v^2/12.96\ R + W \times C/1500$……………………….. (2)

Substitute from eqn. 1 in eqn. 2.

$H = \mu \times W/2 + (W/g) \times v^2/12.96\ R + (15\ W \times G \times (\text{Tan} < F)) / 1500$

Thus, the following model can be introduced for the resultant static transversal force acting on the outer rail of turnouts.

$H = \mu \times W/2 \times \cos\theta + (W/g) \times v^2/12.96\ R + (W \times G \times (\text{Tan} < F)) / 100$ ……………….. (3)

To obtain values of (H) which correspond to different values of (G), the model in (3) for turnout 1 in 8 and the case study of greater Cairo metro line 3 where ($v = 35$ km/h, $W/2 = 75$ kN, $R = 154.525$ m and $F = 7.125^0$) is applied. The obtained values are given in Table 2.

Table 2

Values of H- Load Corresponding to Different Grades (G).

G %	1	2	3	4
1st Term (Sliding force)	18.75	18.75	18.75	18.75
2nd Term (Centrifugal force)	9.353	9.353	9.353	9.353
3rd Term (Grade force)	0.187	0.375	0.561	0.748
H- Load (kN)	28.290	28.478	28.664	28.851

4.3. Simulation Results

To determine the effect of the transvers force (H) on the stability of the fastening system, the relationship between the force (H) and the rail displacement is plotted in Fig. 10 (a) for case of 75 kN vertical load. Also, the impacting of force (H) on the shear and principle stresses (Von Mises) in inner rail clip is illustrated in Fig. 10 (b) and Fig. 10 (c) respectively.

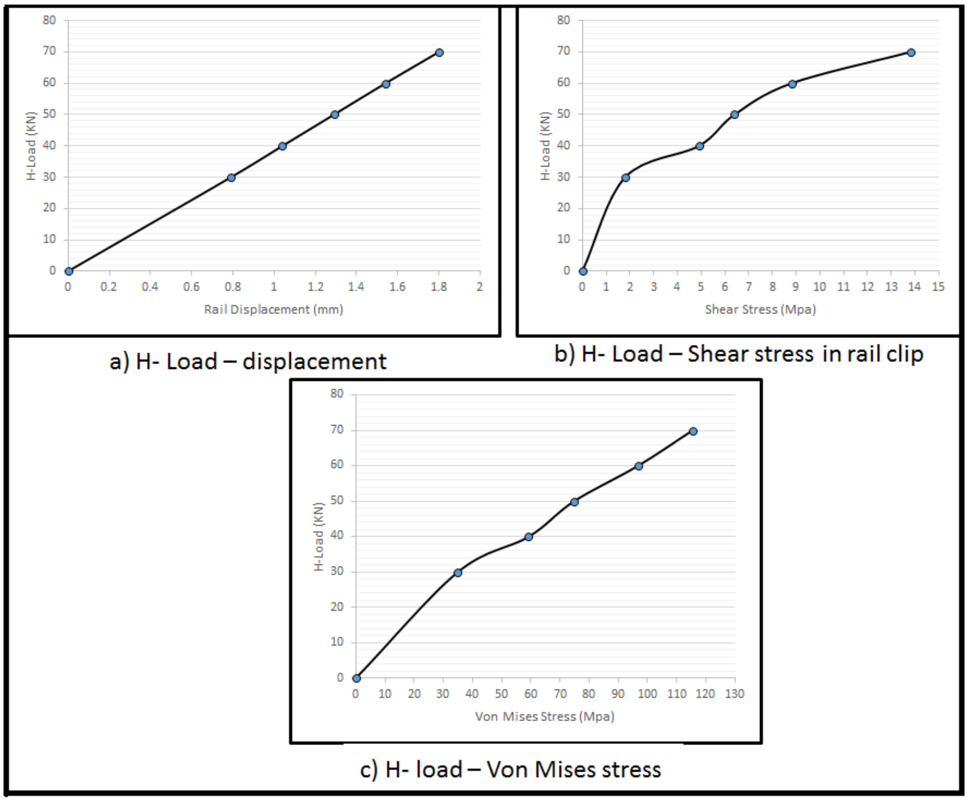

Fig. 10.

Effect of H- Load on Rail Displacement (a) and Inner Clip Stresses of Outer Closure Rail (b), (c).

4.4. Discussion

It is indicated from recorded values in Table 2 and Figs. 9 and 10 that values of shear and principle stresses at rail clip are kept below the allowable values even in case of maximum allowable grade for electrified lines (G= 4%). For G = 2% (Case study for Cairo metro line 3), maximum static H - force = 28.478 kN. As the running speed of trains on the turnout is 35 km/h, the dynamic factor according to Zimmerman = 1.04. Therefore the maximum H-force = 29.64 × 1.04 = 29.64 kN. Thus the corresponding rail displacement = 0.8 mm, maximum shear stress at the upper surface of inner rail clip = 1.8 Mpa and 10 MPa at the contact surface between rail and inner clip. The maximum principle stress (Von Mises) in the upper surface of the inner rail clip = 35 Mpa and 100 Mpa at the contact surface between rail and inner clip. Thus, values of the transvers load (H) are not significantly influenced by increasing the longitudinal grade (G). But the major effect is generating the sliding and centrifugal forces which acting towards the outer rail. These unbalanced forces cause higher rail displacement and vibrate the fastening system. As a result of the produced contact pressure between rail base and inner clip (100 MPa) as shown in Fig. 9 (c), the clip is lifted up. Therefore, the induced vibrations and fatigue stress initiate internal cracks in the inner clip of the outer rail.

5. Conclusion

This paper focused on investigating the influence of longitudinal gradients on the mechanical behavior of fastening systems of turnouts. So, different analyses have been carried out in this paper; analytical modeling, finite element modeling and experimental works. The conclusion of the results is summarized as follows:

1- Longitudinal grades cause negative cant in the outer closure rail of the down slope-start turnout of crossover; vice versa, they cause positive cant in the slope–end turnout.
2- Values of the transvers load on the outer rail head of the down slope-start turnout are not significantly influenced by increasing the longitudinal grades.
3- As a result of longitudinal grades sliding and centrifugal forces acting towards the outer closure rail of the down slope-start turnout are generated.
4- Induced vibrations and fatigue stress initiate internal cracks in the inner clip of the outer closure rail of the down slope-start turnout.
5- A turnout located at start of down-slope for diverging train movement is not recommended.

POSSIBILITIES OF DEVELOPMENT OF RAILWAY SIDINGS IN THE SLOVAK REPUBLIC

Vladislav Zitrický[1], Lenka Černá[2], Ján Ponický[3]
[1,2,3] *University of Žilina, The Faculty of Operation and Economics of Transport and Communications, Žilina, Slovakia*

Abstract: Railway sidings are currently one of important part of the railway operation and their uses directly influence the position of railways in the transport market. Without the support for railway siding operation it is impossible to develop the railway freight transport and then fulfil the objectives of European Commission, which are presented in the "White Paper - Roadmap to a Single European Transport Area - Towards a competitive and resource efficient transport system". Trend of the interest in the rail transport has been decreasing for last 25 years and this fact influences the transport volume in railway siding operation. 25 years ago Slovak economy changed from a planned to a market economy and since then the number of active railway sidings has been decreasing continually. Therefore it is necessary to find effective methods for support and development of railway transport in the Slovak Republic. In the Slovak Republic there are many railway sidings which have an active licence for operation but have no transport performance in the railway transport. There are several reasons for this situation, but the most important ones are financial requirements for railway siding operation, prices in railway freight transport and routing of freight flows, too. Elimination of these adverse factors is presented herein. This paper is focused on the possibilities of development of railway sidings operation in the Slovak Republic. The article contains analysis operations conditions of railway sidings as well as the position of railway sidings in the railway freight transport, and their influence on the performance of the railway transport. In the article there are presented factors of gradual performance decline and proposals for development of railway sidings operation.

Keywords: railway siding, transport, development, Slovak Republic.

1. Introduction

Currently the number of active rail sidings influences the position of rail freight transport in the Slovak transport market. Trend of active rail sidings, which participate on the rail transport performance, has been decreasing for last 25 years. This fact is caused by the change of a political system in the Slovak Republic and by the transformation of the national economy from a planned to a market economy. The paper includes an analysis of railway sidings operation in the Slovak Republic and an analysis of a relationship between transport performance and the number of active railway sidings (or the gross domestic product), and it also includes a proposal for development of railway sidings.

The scientific methodology used in the paper is divided into several steps and it is focused on the proposal regarding the operation of railway sidings development in the Slovak Republic. The first step of the methodology defines issues of railway sidings and objectives of research. The research part includes an analysis of railway sidings operation, transport performance in the Slovak Republic by the transport mode, causes of the decline of active railway sidings, the gross domestic product and a definition of a correlation analysis. The correlation analysis is used to determine a statistical dependence between selected quantitative variables.

The realisation phase of the methodology includes data collection and its interpretation, and mathematical expression of a correlation coefficient. The end of the paper is oriented on the proposal for development of railway sidings operation by the RFID technology for an information system that is used in the railway operation, state support for rail operation and possibilities of connecting logistic centres in the Slovak rail network. Proposals for development of railway sidings are based on the analysis and come from the research literature.

2. Transport Market and Challenges of Railway Sidings in the Slovak Republic

2.1. Gross Domestic Product and Transport Market in the Slovak Republic

As Ľoch and Dolinayová wrote the transformation of Slovak national economy after the year 1990 brought a gradual increase of the gross domestic product. This increase was influenced mainly by political changes. Political changes supported the possibility of the Slovak Republic to enter into the European Union and it is part of global economy.

In the Figure 1 we can see a continuous increase of the gross domestic product of the Slovak Republic. Based on the presented figure we can say that the growth rate of the gross domestic product featured a relative increase, which reflects the percentage ratio of the absolute gross domestic product and the achieved level of a real output in the previous period. The increase of the gross domestic product has also influenced transport performance in the Slovak Republic and has brought new trends which must gradually be solved in the transport market. The biggest problem which Slovak Republic had to solve in the era of transforming the economy was creating a new transport condition for all modes of transport. New transport and market conditions also meant new possibilities for a private sector – liberalisation of transport market. Firstly the road transport market was liberalised; which was a relatively quick process. Liberalisation of rail transport market was a long process and had some negative impacts on the transport performance in rail transport. Currently all modes of transport in the Slovak Republic have been liberalised in the

[1] Corresponding author: vladislav.zitricky@fpedas.uniza.sk

market and a competitive environment has been created. Competition exists not only between transport modes, but now it is a free competition also between the carriers of each transport mode.

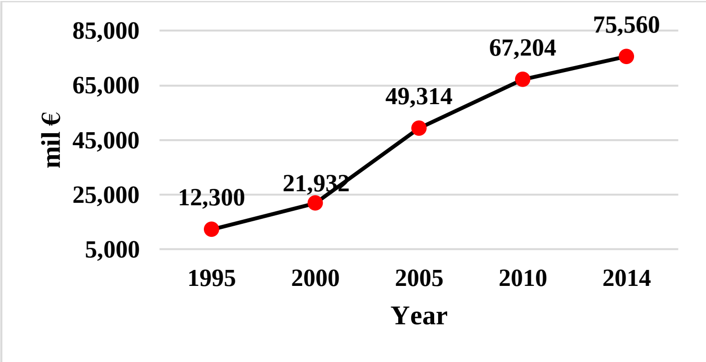

Fig. 1.
Gross Domestic Product in the Slovak Republic
Source: (Yearbooks of transport, Slovak Republic)

Political and economic changes have also transformed transport market during last 25 years. Road transport gradually obtained a majority position in the transport market. In the Table 1 and Figure 1 we can see a significant increase of their transport performance. On Slovak railway sidings there is realised a main part of rail freight transport performance, even though the performance has been decreasing for last years. They are mainly on bulk substrates coming from the extraction, transport of chemicals, iron, wood, automobiles, etc. Based on the statistical data published in Yearbooks of transport, statistical database of data-set was created, which includes data from years 1995, 2000, 2005, 2010 and 2014. The overview of transport performance is in the Table 1.

Table 1
Performance by the Transport Mode in the Slovak Republic

Indicator/Year		1995	2000	2005	2010	2014
Number of railway sidings		643	575	506	393	302
Transport performance [mil. net ton km]	Road transport	5,158	10,042	22,550	27,411	31,304
	Railway transport	13,764	11,234	9,463	8,105	8,829
	Water transport	1,468	1,383	680	2,166	684
	All modes of transport	20,390	22,659	32,693	37,682	40,817
Gross domestic product [mil. €]		12,300	21,932	49,314	67,204	75,560

Source: (Yearbooks of transport, Slovak Republic)

Dolinayová, Ľoch and Kanis declare that the greatest amount of goods transported is realised by the road transport and till the year 2005 it had a fluctuating character. After the year 2005 to year 2010 freight transport had a lower growth rate. It was caused by the great world economic and financial crisis, which started in 2009. After the crisis the trend of transport volume in road transport grew again. Transport volume in rail transport had a decreasing character till the 2010 and after this year this negative trend was stopped, and in the year 2014 the transport volume was slightly higher than in the year 2010. In the Figure 2 we can see a graphical representation of transport volume for the reported period.
Water transport is a minority transport mode in the Slovak Republic, as Jurkovič and Dávid said, and its transport volume is negligible opposite to road and rail transport.

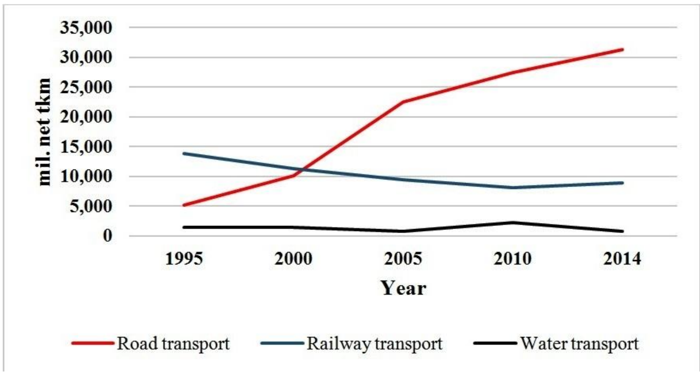

Fig. 2.
Transport Performances in Freight Transport
Source: (Yearbooks of transport, Slovak Republic)

2.2. Position of Railway Sidings in the Transport Market in the Slovak Republic

Kejíková and Klapita and also Abramovič, Brnjac and Škrinjar declare the importance of railway sidings in rail operation, and their status is of a significant meaning. Transport volume on the railway sidings creates the majority share on the whole rail transport volume. From this fact it is necessary to monitor and develop the area of railway sidings and at the same time transport market conditions have to be taken into account. The decreasing trend of rail transport volume in the European Union has been reflected in the Slovak Republic, too.
Most of railway sidings have a still active licence for operation, but their performance is minimal or none. It is caused by the financial conditions for operation, pricing in the rail freight transport and orientation of transport flows. Industrial companies in the Slovak Republic transported the majority of goods by the rail transport till the 90s in the last century. Political and economic changes have brought a decreasing trend of transport volume in rail transport until these days. On the other hand transport volume in road transport has had a growing trend. Among results of this fact there is an increase of congestion and overloading of highways and first class roads. Most of railway sidings were cancelled or function in a restricted regime only. The destiny of most non-active railway sidings is considerably problematic. Several railway sidings are available for sale, but there is no interest in buying them on the real market. Some railway sidings have an unknown owner, because the subject stopped his business many years ago.

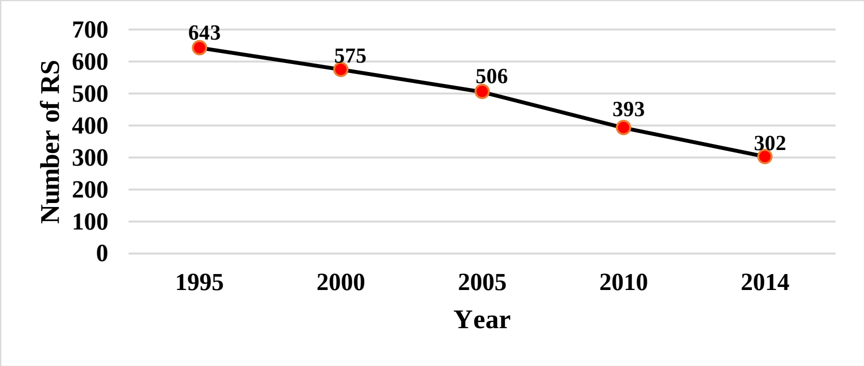

Fig. 3.
The Number of Railway Sidings in the Slovak Republic
Source: (Yearbooks of transport, Slovak Republic; Lovíšek and Dolinayová, Daniš and Čamaj)

In the Figure 3 there is an overview of development of the number of railway sidings for the reported period. The number of railway sidings has had a decreasing slope. Despite of this fact railway sidings still have a majority share on the rail transport performance. In the Figure 4 we can see a share between single wagon loads and block trains which are operated between railway sidings.

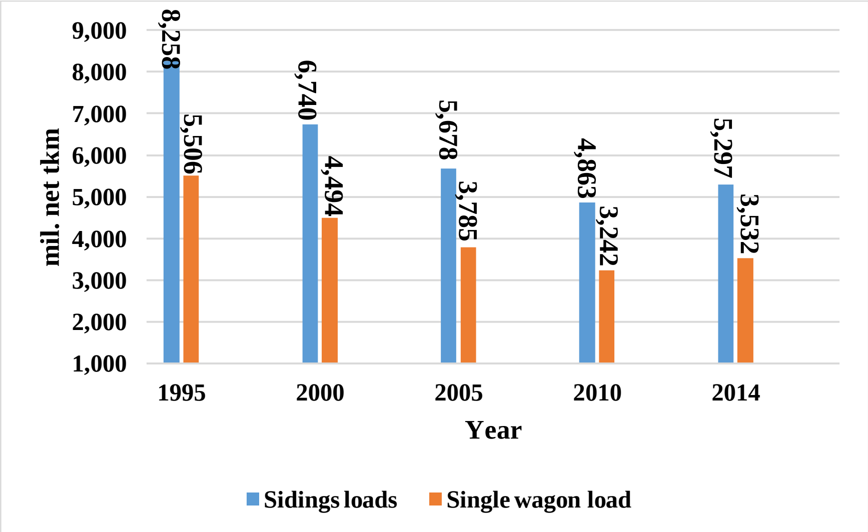

Fig. 4.
Performance of Rail Transport
Source: (Study and Survey of Railway Sidings, ŽSR)

Based on the Study and Survey of ŽSR on railway sidings that was realised between the owner of railway sidings and carriers we can see an interesting usage of railway sidings. However the survey also showed a great weakness of this transport type. It revealed the weakness on the side of an infrastructure manager (ŽSR), railway undertakings (national and private) and also of the owners of railway sidings. The most relevant weaknesses are: data update by means of communication, efficient usage of information and update of transport condition (technical and operation). Another great problem was identified in the form of a small state support for the transport area, specifically for railway transport. For example many users of railway transport (not only the owner of railway sidings) expect a more effective support from the state for the rail infrastructure.

2.3. Correlation Analysis

Based on Benko's definition "Correlation is a mutual linear relation (dependence) of two random variables X and Y. This relation can be direct (if one variable increases, then second variable increases, too), or indirect (with one variable growth there is a fall of the second one)" (http://fstroj.uniza.sk/kam/orsansky/pdf/zakladystatistiky.pdf)
Mathematical calculation, which results in numerical data talking about the dependence of two or more elements of statistical data-set, is called a correlation number. The correlation coefficient r(x, y) represents the dependency of two variables x and y from the statistical data-set. This dependence is expressed with a statistic covariance cov (x, y):

$$\mathrm{cov}_{(x,y)} = \frac{1}{n-1} * \sum_{i=1}^{n} \left(x_i - \bar{x}\right) * (y_i - \bar{y}) \tag{1}$$

After calculating cov (x, y) we can further determine the correlation coefficient according to the formula:

$$r_{(x,y)} = \frac{k_{(x,y)}}{s_x * s_y} \tag{2}$$

Palkovič says the value of correlation coefficient expresses a linear degree of dependency of variables x and y. Value of correlation coefficient is from -1 to 1. When values of correlation coefficient are 0, there exists no relation, i.e. no dependence between the variables. When the value is 1, then the variables are directly dependent. When the value of correlation coefficient is -1, then the variables are indirectly dependent.
In the Figure 5 the correlation relationship is shown and the correlation coefficient between the gross domestic product of the Slovak Republic and total transport volume in Slovakia is calculated.

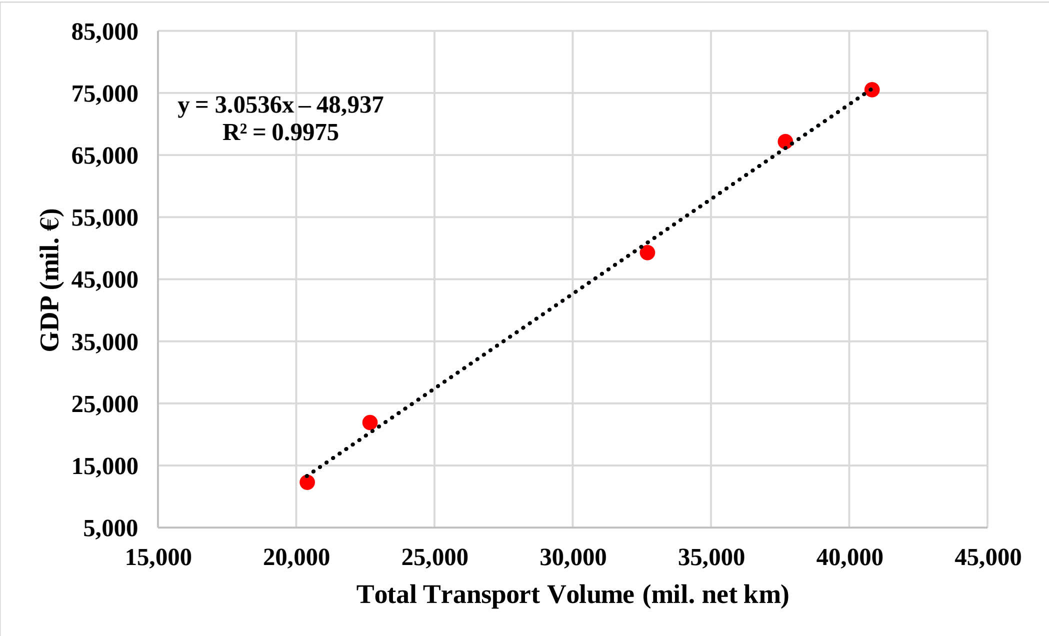

Fig. 5.
Relation between Total Transport Volume and the Gross Domestic Product
Source: (Authors; based on the statistical data)

Based on the calculated correlation between the gross domestic product and total transport volume in the Slovak Republic we can claim a very strong dependency. Correlation coefficient has a value 0.999 and the Pearson's coefficient is 1.00. Variability of the gross domestic product is 99%. The result of correlation analysis shows that the gross domestic product and total transport volume are changing their direction. In this case it is obvious: any increase of the gross domestic product means the growth of transport performance.
In the Figure 6 there is a correlation analysis between the number of railway sidings and transport volume in the Slovak Republic.

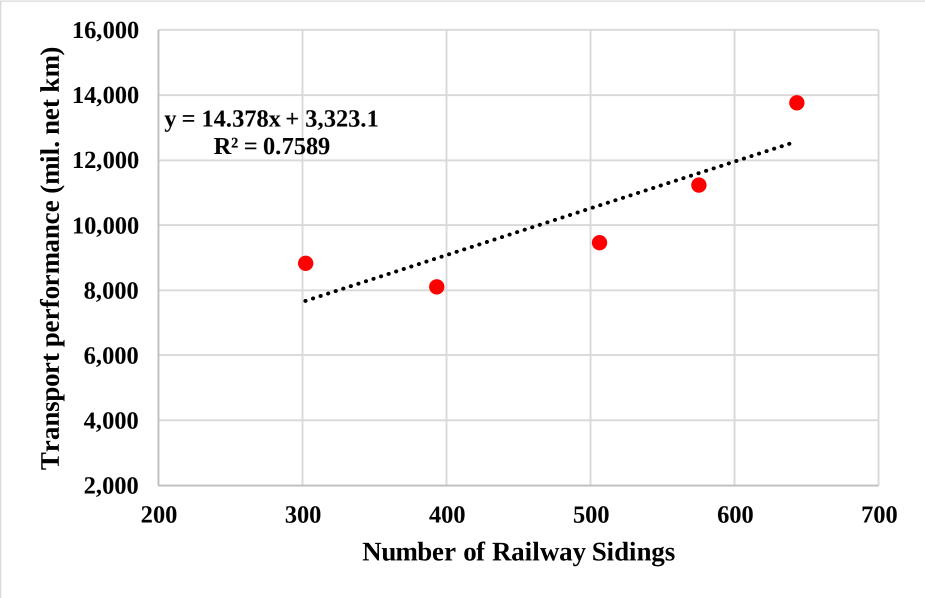

Fig. 6.
Relation between Rail Transport Performance and the Number of Railway Sidings
Source: (Authors; based on the statistical data)

Simple linear correlation between the number of railway sidings and rail transport performance is very strong for the reported period. Correlation coefficient has a value 0.871 and Pearson's coefficient is 0.87. Based on the calculated correlation we can say that if there were no railway sidings in the Slovak Republic, the transport performance in rail freight transport would be 3 323 mil. net kilometres per year. Variability of the transport performance is 76%. Both correlations' coefficients have values that represent the highest positive correlation. Both computed values (number of railway sidings and transport volume) are changing together by the same direction and they have a strong dependency.
Results of correlation analysis show a strong dependency between rail freight transport performance and the number of railway sidings. Therefore it is necessary to directly support development of railway sidings infrastructure and consequently a positive development of the whole freight rail transport can be expected. The result will be the development of rail transport based on the determined objectives of the European Union, which are contained in the White Paper: Roadmap to a Single European Transport Area - Towards a competitive and resource efficient transport system, as said Gašparík, Abramivič and Halás.

3. Proposals for Development of Railway Sidings

Proposals for development of railway sidings in the Slovak Republic are oriented on three points. First proposal consists of using the RFID technology. Second is about the state government supporting the railway sidings and third proposal describes possibilities of connecting logistics centres in the railway infrastructure.

3.1. RFID technology

An efficient management of railway sidings in Slovakia lies in the use and processing of information. It is however one of the weaknesses of rail operation in railway sidings. These weaknesses are also mentioned in the survey described in chapter 2.2 of this paper. Based on this fact we describe a possibility to use RFID technology in railway sidings as one factor of support to develop rail operation on railway sidings.
Support of applying RFID technology to railways sidings requires the existence of an information system for railway sidings (ISRS). Currently this condition is a problem on railway sidings in the Slovak Republic, as Lovíšek published in his dissertation thesis, because main railway sidings operators have an own information system (for example the company US Steel, a. s., or Slovnaft, a. s.); small railway sidings don't have any information systems and the communication between rail operators still functions in the "paper" form.
Problem of this field lies in a manual typing of information to operators' system; it relates to wagons, shipment, locomotives, loading, weighing and delivery wagons for carriage by rail. Sometimes retyping information from paper to an information system of a rail operator causes errors and then it generates mistakes in rail operation on the transport route of shipment. Other great mistakes for example occur in payment for transport.
Proposed RFID technology provides a full automation of collecting, processing and providing the information. The system consists of the following parts:

- **Stationary part** – this part represents an automatic identification of wagons when they enter and leave the railway siding area. In this part a scanning device (gate) in the scanning process is necessary,

- **Mobile part** – identification of wagons which will be run by an operator using a mobile computer connected to a scanning device.

Stationary part is advantageous to be built on great railway sidings that have a high volume of transport, for example near railway weights. Mobile part is advantageous for small railway sidings. This technology is very expensive; therefore we propose these two parts of RFID technology in rail operation.
RFID tags must also consist of two parts. The first part carries permanent information about technical characteristics of rail wagon (number of axes, wagon number and weight...). The second part of the tag is rewritable and there will be information about consignments (weight, number of pieces, ID number, sending and delivery station, and more information that is in the consignment note).
In the Figure 7 there is a schematic representation of automatic data processing of wagon load on the railway siding after the application of RFID technology.

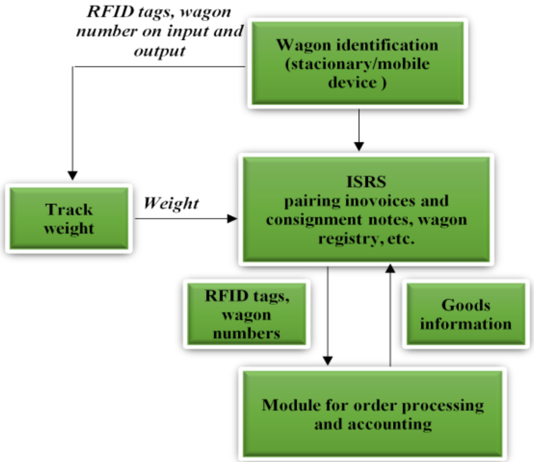

Fig. 7.
Data Processing Scheme of Wagon Load by RFID Technology
Source: (Authors)

A problematic part of RFID technology is its economic side in rail operation. Effective usage of RFID technology requires introducing this technology not only into the whole rail sector, but also to its users. This process is rather expensive despite of its advantages. The Slovak Republic is a transit country from transport flows side and domestic volume of transport is about 14% only. Introduction of RFID technology on Slovak railway sidings doesn't have a significant importance without using it in the international rail transport.

3.2. State Support for Railway Sidings

International and political status of the Slovak Republic creates a pressure on the government and their decisions. Government's decisions must reflect the position of the Slovak Republic as a member of the European Union and reflect their requirements not only for a transport sector. Currently it is necessary to reflect the situation regarding the environment; and rail transport is one possibility how to fulfil ecological requirements.
Transport is one of the greatest air pollutants and it is exposed to a constant pressure under environmental activities. Therefore the European Union passes legislative measures on its protection. White paper, as Gašparík, Abramivič, and Halás said, has an objective to transfer 50% of transported goods from road to environment friendly transport mode till the year 2050. This ambitious aim is impossible without the support of state and governments for railway sidings sector.
State support is possible in several forms. First and easy form is a direct support for infrastructure of railway sidings through the state budget. Maintenance costs of railway sidings are very high and present unprofitable investments for several companies. Through the national infrastructure manager it is possible to unload companies from maintenance costs and achieve a more attractive railway transport. State support must be formed on a non-discriminatory principle and shouldn't restrict competition between transport modes.
Another possible state support for railway sidings operation is through tax credits. For example when companies transport their goods by rail transport they can pay lower taxes to state budget. This solution can solve a great difference between pricing in road and rail transport, as Dolinayová, Daniš and Čamaj said.
Except for the state support having a positive influence on the development of railway siding operation, it is a risk for the state budget. Main means of transport in the Slovak Republic is the road transport. If we decrease income of this mode of transport, it can have a negative impact on the gross domestic product. In chapter 2.3 we showed a very close correlation between transport volume and the gross domestic product. And when transport volume decreases, then the gross domestic product falls, too. Therefore it is important that any changes in the state budget should be undertaken with caution.

3.3. Railway Sidings Connection to Logistics Centres

Slovak economy after transformation made conditions for arrival of foreign investors, who influenced building of logistic centres. The character of logistic centres requires their modality, i.e. their connection to multiple transport modes, but nevertheless in the Slovak Republic such a centre was built without a connection within the railway infrastructure. This fact is caused on one side by costs and on the other side by the fact that the state doesn't have a good national general plan for transport. Therefore we suggest to build a new logistic centre while ensuring its automatic connection to rail infrastructure through railway siding.

The proposal of connecting logistic centres to rail infrastructure is not so costly; it is one form of the state support through legislative measures. The risk of this proposal lies in the loss of a foreign capital since the rail transport has a demanding technology processing of consignment.

Nevertheless this risk factor exists potentially in the intermodal transport. Intermodal transport is growing at a high rate early and then it represents the assumption of a better usage of railway transport in the Slovak transport market.

4. Conclusion

In the past railway sidings served for mining and metallurgical companies; currently they have utilization for different companies. Disadvantageous conditions and a high competition of road transport cause in several cases the reduction of transport volume on railway sidings. Analysis showed a great importance of railway sidings in Slovak rail transport and their gradual disappearance can result in the decline of rail transport in the Slovak Republic. A problematic point is that many railway sidings have an active licence in the operation, but they don't have transport performance. Building new railway sidings is also a negative factor in this challenge, because in the last 25 years too few new railway sidings were built. Liberalisation of rail transport market based on the European Union conditions didn't bring any improvements in this field.

The aim of the paper was to provide proposals for development of railway sidings operation in the Slovak Republic. Based on the calculated correlation the relationship between the gross domestic product and total transport volume was analysed. Next step of analysis was the assessment of the relationship between railway siding and transport volume in rail transport. Both realised analyses showed a great correlation relation and a significant influence of railway sidings on the transport market. Based on the characterised problematics and analyses we proposed three ways for development of railway sidings in the Slovak Republic. Every solution that was proposed has own strengths and weaknesses, but ultimately can lead to a recovery of rail transport in the Slovak Republic.

Acknowledgements

The paper is supported by the VEGA Agency by the Project 1/0095/16 "Assessment of the quality of connections on the transport network as a tool to enhance the competitiveness of public passenger transport system" that is solved at Faculty of Operations and Economics of Transport and Communication, University of Žilina.

DEVELOPMENT OF THE PUBLIC TENDER OF PATHS ORDERING IN LONG-DISTANCE RAIL TRANSPORT IN THE SLOVAK REPUBLIC

Lumír Pečený[1], Jozef Gašparík[2], Veronika Gáborová[3]
[1,2,3] Department of Railway Transport, Faculty of Operation and Economics of Transport and Communications, University of Zilina, Univerzitná 1, 010 26, Žilina, Slovakia

Abstract: Since the early 1990s, the number of passengers on public transport has declined. One of the reasons is the decrease in population movements in the second half of the 1990s, but a much more serious one is the transition of people from public transport to individual transport. The consequence is that, despite increasing population movement in recent years, the performance of public transport is still declining. Great emphasis is now placed on the quality of services provided by rail passenger transport, which is influenced by several factors. The competition between operators in a public tender when ordering paths in long-distance rail passenger transport is highly significant. The Slovak Republic has made progress in adopting European Union transport policy in separating out transport operators from infrastructure. At present, the Republic has gradually started to apply public tenders to private operators in a liberalised transport market. The aim of this article is to analyse the steps taken by the Slovak government in the announcement of the first public tenders to provide subsidised transport on a selected line and to determine the conditions for this tender.

Keywords: liberalisation of passenger transport, public performance, public tender, Slovak Republic.

1. Introduction

The partial liberalisation of the rail market in the European Union (EU) was already underway in 2010, when all European railway companies with the necessary licences and safety certificates gained access to railway infrastructure in all Member States. However, this only caused the opening up of the market for international rail passenger transport, and did not cover the opening up of domestic rail passenger transport markets in Member States. Currently, there is only a fully open market for rail passenger transport in Sweden and the United Kingdom. In Germany, Austria, Italy, the Czech Republic, and the Netherlands there is a partially open market for new railway undertakings.
One of the current objectives of the common transport policy laid down in The fourth railway package is to open up the market for national rail passenger services in all Member States from 2019, while making public tenders for transport service contracts compulsory, in the public interest.

2. Steps towards liberalisation and the opening up of the rail passenger market in the European Union

A fundamental step in the liberalisation of the rail freight market has been the separation of railway infrastructure managers from railway companies and consequently providing non-discriminatory access to railway infrastructure to the railway companies in all Member States. Opening up the market to new private companies means that several transport companies can compete directly for selected lines at the same time. Given that passenger transport is a State instrument of transport, regional and social policy to provide transport services, it is still largely controlled by the State (Kvizda, M. 2013).
The biggest problem in the opening up of domestic passenger transport is that the tracks upon which traffic is controlled is also subsidised by the State, because it is impossible to create a natural competitive market. The situation has improved because of the impact of European reforms, although the operation of these lines remains costly, so it is not possible to create transparent competition. For this reason, the State continues to control and subsidise traffic performance but the possibility of public competition to secure operations on selected routes followed by their state subsidies is increasingly coming to the fore (Drdla, P. 2014).
On lines with a high volume of operations and a sufficient number of passengers, the situation is more favourable, because railway operators can provide transport services without direct state subsidies, at their own business risk. Competition has thus developed along these lines more slowly but it currently exists on some lines in Member States and they are mainly connecting lines between big towns. In the Slovak Republic, the Bratislava to Košice line is operated this way, as is the Ostrava to Prague line in the neighbouring Czech Republic.
In 2009, the European Parliament and Council Regulation EC No. 1370/2007 came into force, which sets out the selection procedures for the award of contracts in public rail transport. The Slovak Republic's Ministry of Transport, Construction and Regional Development (MDVRR) contracted with the best railway company operating rail services (Železničná spoločnosť Slovensko, a.s., The Railway Company Slovakia Inc., or ZSSK) to carry out transport services in the public interest for a period of nine years (2011 to 2020). This contract also includes operations in regional transport, which are agreed together with operations in long-distance transport.

[1] Corresponding author: lumir.peceny@fpedas.uniza.sk

2.1. The opening up of the market for domestic passenger rail transport services in the Slovak Republic

There are two railway companies with which the State has concluded contracts for transport services in the public interest for domestic passenger transport in the Slovak Republic: ZSSK and the private railway company, RegioJet, Inc. Currently, nine railway companies have a valid licence for the provision of services in public passenger transport. MDVRR commissions regional transport and long-distance transport in the Slovak Republic.
At present, there are two options of providing transport services on the railway infrastructure of the Slovak national infrastructure manager (Železnice Slovenskej Republiky, Railways of the Slovak Republic, or ŽSR). The first is when a railway company provides transport services at its own business risk and this principle is applied to lines with sufficient capacity and performance, where there is less risk of potential financial loss to the company. Currently this type of provision of transport service is used by RegioJet Intercity on the Bratislava to Košice line. The second type is when a railway company provides transport services in the public interest.
Until 2012, the market for domestic passenger transport was virtually closed and all contracts for public transport services were concluded between MDVRR and ZSSK. All ZSSK operations were realised as public transport services and the State reimbursed verifiable losses to the company. This situation changed in 2012 after the entry of a new railway company into the market for passenger rail transport, the RegioJet company, which started operating regional rail passenger transport on the Bratislava to Komarno line on the basis of direct appointment and contracting of transport services in the public interest (Kendra, M.; Masek, J. 2013).
In January 2012, there was a change on the Bratislava to Košice line because of a sufficient number of services and passenger traffic flows. ZSSK started to operate its Intercity trains as commercial trains from a contract on traffic performance in the public interest. For these trains, there is a separate tariff policy, they are not subsidised by the State and the railway company operates at its own business risk. In December 2014, RegioJet started providing the same transport services on the same line, with the result that ZSSK stopped operating its Intercity trains in January 2016.

2.2. Call for public tenders in railway transport in the Slovak Republic

There are two forms of contracts for transport services in the public interest, either by tendering the competition for traffic performance following the end of a contract, or by directly entering the selected railway company. A contract for transport services in the public interest by direct assignment to a railway company was realised on the Bratislava to Komarno line. MDVRR carried out a tender and awarded the transport service to a specific railway company, RegioJet. The contract was agreed in December 2010 for a period of nine years from March 2012 to December 2020 and the contracted transport performance was stipulated at 1.3 million train kilometres (Kendra, M.; Masek, J. 2013).
The analysis by MDVRR showed that, after RegioJet took on the railway passenger transport March 2012, there was visibly increased train traffic on this track (from Dunajska Streda to Bratislava there is a one hour period during the day, and half an hour period during peak time), and as a result there is a significant increase in transport performance.
Year on year, in the period October 2012 to October 2013, there was an increase of 74% in train kilometres, 146% in passenger kilometres, and 115% in the number of passengers of. It was also noted that there was a reduction in the cost per train kilometre of 5.7€, which represents a cost reduction of 16% when compared with a national carrier.
In September 2015, the first competition for subsidised services in the public interest started, when advance notice of invitation to tender for the long-distance Bratislava to Banska Bystrica line was published and, in November, the tender was declared without publication of the estimated value of services. The price of the services, however, is estimated at over 10 million euros. The deadline for this competition was January 2016 and eight candidates enrolled. As at August 2016, the competition had not yet been evaluated (Páteček, P. 2016).

2.3. The long-distance Bratislava to Banska Bystrica line

During 2015, MDVRR began to take steps towards the liberalisation of the long-distance domestic rail passenger service on the Bratislava to Banska Bystrica line, which opened up the market for domestic passenger services to a new railway company. The Bratislava to Banska Bystrica line was chosen because of the provision of sufficient transport performance and passenger flows. The liberalisation process of the Bratislava to Banska Bystrica line is still ongoing, and has entered competitive conditions and criteria stage, although the tender had yet to be concluded in 2015 (Kremensky, P. 2015).
The object of the competition was to ensure safe, effective and quality transport services to passengers between the cities of Bratislava and Banska Bystrica by long-distance trains. The contract for transport services in the public interest will be concluded with an eventual candidate under the Act of Railroad No. 514/2009. Annual transport performance is expected to be in the range of about 1.5 million train kilometres and the extent of transport operations for the year will be specified by a special addition to the contract. For realised traffic performance, the State will reimburse verifiable losses to the railway companies. In 2016, the extent of total transport performance at ZSSK represented 31,304 million train kilometres, thus the competitive amount represents 4.79% of train kilometres operated by ZSSK.
The Ministry declared that one of the objectives of the competition was to generate the most favourable economic conditions for both the State and the passenger, while ensuring the operation of services achieved the required quality. The State currently reimburses around 6.7€ per train kilometre to ZSSK. Provisionally in this contest it envisaged the

inclusion of eight pairs of express trains, which run daily, and two pairs of relief trains running on Friday and Sunday. (Zitrický, Gašparík and Pečený, 2015).
The 2015/16 timetable on the Bratislava to Banska Bystrica line operates nine direct express trains, including eight trains in a two-hour period during the day. Also in the opposite direction there are nine direct express trains, including three trains in the morning one-hour period and the remaining six trains in a two-hour period. The transport has a length of 230 kilometres, achieved travel time is three hours 24 minutes and the average cruising speed is 67.6 kilometres per hour.

2.4. Possible obstacles to the operation of the long-distance Bratislava to Banska Bystrica line

Based on an analysis of the previous steps of the Slovak government in opening up the rail market in the Slovak Republic by process of a competition for a long-distance line, we can define threats and obstacles in two ways: infrastructure assumptions, and operational/technological aspects. To analyse the railway infrastructure which makes up the Bratislava to Banska Bystrica line, we have to evaluate the category and the technical level of infrastructure elements:

- Bratislava to Palárikovo (as part of the corridor lines of Bratislava to Štúrovo)
- Palárikovo to Šurany to Levice to Dúbrava to Zvolen
- Zvolen to Banska Bystrica (as part of the track Zvolen to Banska Bystrica to Diviaky to Vrútky)

Selected technical characteristics of the track sections are shown in Table 1.

Table 1
Technical characteristics of selected track sections

Track	**Track category**	**Number of track lines**	**Maximum track speed [km/h]**	**Train length norm[m]**	**Capacity [trains/day]**
Bratislava – Palarikovo	1	2	140	700	140/140
Palarikovo – Kozarovce	2	1	100	540	86
Kozarovce – Hronska Dubrava – Zvolen	2	1/2	100	540	75
Zvolen – Banska Bystrica	2	1	100	500	105

Source: authors

The Bratislava to Palarikovo track section is a double-track line, included in international pan-European corridors, but this track section has been not modernised. The maximum speed is 140 km/h in the Senec to Sladkovicovo section and 120 km/h for the rest of the track. From Palarikovo, there is a single-track line to Banska Bystrica (except for short double-track sections Zarnovica to Ziar nad Hronom and Hronska Dubrava to Zvolen). A detailed speed profile is shown in Figure 1. The low line speed (maximum 100 km/h, but most of the sections are built only to 80 km/h) and outdated station and track safety devices (without train protection) cause low throughput capacity of the track section, with long time intervals planning trains crossing in the station. In 2014, two passing points were abolished, which reduced the capacity of the lines even more. The result is a low running speed for long-distance trains because of stopping trains for traffic reasons causing delay to other trains (Ľupták and Ponický, 2015).
Finally, the provision of transport process is at a low level as well. There is still only phone security devices, semi-automatic block and all-relay safety devices in some sections, as well as a low level of security at the railway crossing. It should be noted that that route is part of the so-called ‘Southern Corridor of ZSR’, a link between Bratislava and Kosice, the biggest cities in the Slovak Republic.

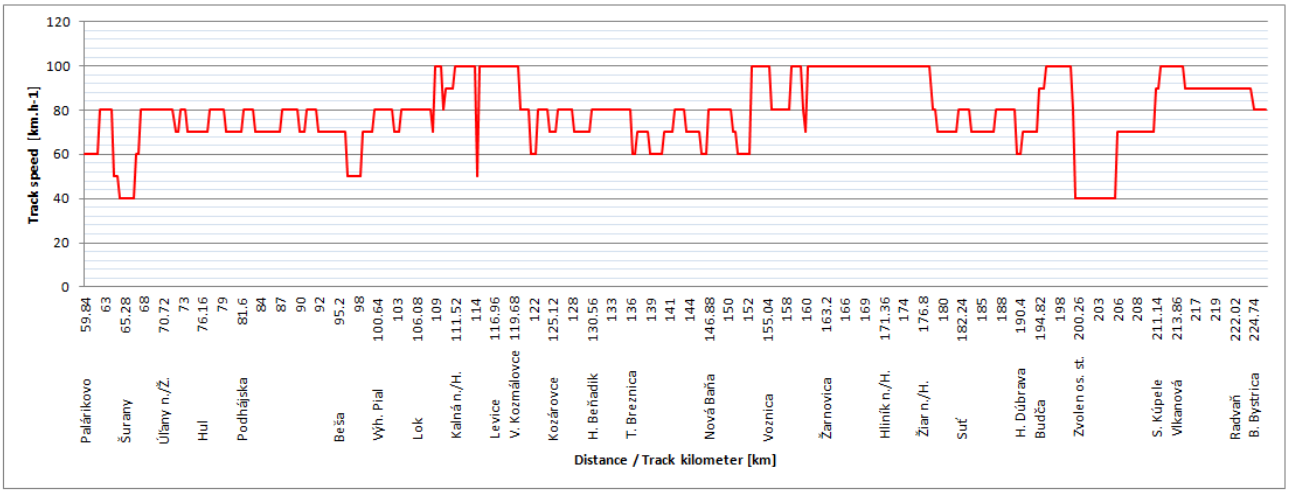

Fig. 1.
Static speed profile of track line Palarikovo to Banska Bystrica
Source: Authors

The opening up of the long-distance rail passenger transport market on lines in bad condition, as has been proven on the Bratislava to Banska Bystrica line, has the following barriers to development:

- limited possibilities for constructing high-quality train traffic diagrams;
- low running speeds;
- difficulties in operational control when there are deviations from the train traffic diagram;
- delays transmitted to other trains when interacting with trains of other railway companies, and
- disputes between railway companies.

In terms of incorporating the long-distance Bratislava to Banska Bystrica line into an open access competition process, the basic problem is the interference with the concept of long-distance passenger transport on the 'southern corridor' as a cut off of the direct fast train Bratislava to Zvolen to Kosice line. This entails creating a separate Bratislava to Banska Bystrica line, with implications for passengers in the form of compulsory transfer at the Zvolen railway station in the direction of Kosice and at the Banska Bystrica railway station in the direction of Zilina. This new concept of operating this line leads to fragmentation tendencies in the rail interconnections network, which can cause a drop in the number of passengers.

The setting of tariff policy and conditions for these trains is also significant, especially in terms of passengers. A problem is the necessity of buying separate travel documents when transferring between state trains and the trains of private railway companies. Difficulties can occur even when setting the connecting links in the Zvolen and Banska Bystrica railway stations between trains of private operators and trains that remain within the competence of the state carrier.

2.5. The proposed framework measures to strengthen competition on the Bratislava to Banska Bystrica line

Framework measures to strengthen free competition on the Bratislava to Banska Bystrica line can be defined within the same structure, i.e., threats and obstacles to infrastructure measurements and operational/technological measurements. Based on an analysis of the current state of the art rail infrastructure, three priority measures have been defined in relation to railway infrastructure:

1. Increasing safety and reliability;
2. Modern and high-quality infrastructure, and
3. Telematics and the support by technical means of ICT.

These priorities correspond to the strategic documents of EU and Slovak Republic transport policy, with respect to rail infrastructure. Improvements in safety should be assessed by the number of railway accidents and their categorisation, and indicators of safety in tunnels and level crossings should also be monitored. The priority of having modern and high quality infrastructure is necessary to eliminate deficiencies related to decline in critical running speeds and capacity deficiencies. The key priority in modernisation is the deployment of telematics applications supported by ICT to achieve a higher quality of traffic management, passenger information and security. Investment in railway infrastructure is a primary prerequisite for the development of competition and providing quality services. Specifically, it is particularly important to promote these infrastructure measures:

- eliminating sections with low running speeds with the general modernisation of permanent ways (a higher level of switches security, eliminating permanent speed restrictions, etc.);
- increasing the capacity of the track section, double-tracking of some overloaded track sections (Zvolen to Banska Bystrica, Levice to Kozarovce), activating cancelled passing points, and building automatic signalling;
- construction of train protection equipment with automatic signalling indications;
- modernisation of level crossing safety devices, including camera systems;

- installation of audiovisual systems for passengers at stations and stops, and
- installation of modern electronic security devices to a central dispatcher station.

Defined infrastructure measures will have a direct impact on the technology of timetabling, shortening travel time and waiting time. It avoids the problem of blame between railway companies due to delays, and railway infrastructure managers will be able to quickly manage the operation of accretion of delays. A particular aspect is the setting of a tariff policy for competing long-distance lines. To maintain the quality of travel and the validity of travel documents, a common tariff policy and tariff conditions must be defined as well as recognition of travel documents for transfer between trains of different railway companies by the order body (MDVRR). Also, when the constructing the train traffic diagram it is necessary to create transfer links (Poliak, Semanova and Varjan, 2014).

3. Conclusion

This is a significant moment in the railway market in the Slovak Republic, preparing the opening up of the market for domestic long-distance passenger rail transport for competition in the provision of transport services in the public interest. This is a comprehensive process that achieves the desired effect only if it is well prepared. This paper identifies two aspects which are essential to ensuring good starting conditions of competition: setting the parameters of the railway infrastructure in terms of capacity and safety performance, and operational and technological aspects, represented by setting a tariff policy and conditions and maintaining connecting links between state and private railway undertakings.

The framework proposal will be able to provide services in a liberalised environment at the required level to meet the needs of the customer, the passenger. The priority, from the perspective of the passenger, is transit time and it should be noted that the line for competition already has a significant competitor in the form of road traffic, with the completion of the highway R1, where travel time is two hours and 50 minutes by bus and two hours and five minutes by car.

ANALYSIS OF THE POSSIBILITIES OF CONSTRUCTION A RAILWAY LINE VAREŠ-BANOVIĆI

Nedžad Branković[1], Smajo Salketić[2], Azra Ferizović[3]
[1,2,3] *Faculty of Traffic and Communications, University of Sarajevo, Sarajevo, Bosnia & Herzegovina*

Abstract: Construction of new railway lines is a significant economic breakthrough and has historical significance. Inconsistent transport policy and marginalizing the significance of railways are the reason of the decades-long stagnation in the expansion of the railway network in Bosnia and Herzegovina. The last major project of regional importance, finalized in 1991, the construction of the Tuzla-Zvornik, which is viewed in a broader context and with more variants. One variant of the construction of the railway Vareš-Banovići and connecting Sarajevo and Belgrade shortest possible rail line. In the context of the new European integration processes, economic developments in B&iH and the region and the projected development of the power sector of Bosnia and Herzegovina, the issue of the construction of the railway Vareš-Banovići takes on a new dimension and over again is updated. The construction of the railway Vareš-Banovići would ensure more efficient binding B&H power sector by rail as the shortest and most economical route. It would, at the same time, mean quality traffic communication between Tuzla and Sarajevo region and reduce travel time to the Port of Ploče for Tuzla economy of over 100 km, and the intense involvement of BiH in Baltic-Adriatic transport flows. The paper emphasize technical-technological and managerial (SWOT) aspects in the function of the sustainability of the railway line Vareš-Banovići project building.

Keywords: railway, power sector, regional integration, SWOT, sustainability.

1. Introducion

The idea of building a railway line Vareš - Banovići and linking Sarajevo and Tuzla in that direction is very old and it is periodically actualized. The first analysis began after World War II, ie. after the construction and putting into operation the railway Brčko-Banovići in 1946. An important step was taken in 1953 when the narrow track railway line Podlugovi –Vareš was abolished and opened newone to traffic lines with normal track gauge on this section. As a logical sequence was the continuing of the construction of the railway line from Banovići to Vareš in order to interrelate these two great mining centers.
Feasibility Study from the seventies has promoted this idea in a wider context: it has been made an analysis of the feasibility of the construction of the railway line Zvornik-Živinice and Banovići-Vareš. According to the aforementioned Study, which examened several variants, the Vareš-Banovići line would be approximately 50 km long passing through mountain ranges Zvijezda and Konjuh.
This involved connecting Bosnia and Herzegovina and Serbia connecting Sarajevo and Belgrade with a new railway route. Analyzes were performed and comparisons in relation to the railway line Tuzla-Doboj-Zenica-Sarajevo. In the end the decision was made to build the Tuzla-Zvornik and finally in 1991 he built the railroad shares Živinice-Zvornik, of a distance of 55 km. This presented the only one direct railway communication with standard gauge of 1435 mm between Sarajevo and Belgrade. The narrow track railway line of 760 mm over the Višegrad was canceled on seventies, and the other two rail lines between Sarajevo and Belgrade (via Vrpolje and Vinkovci) are realized via railways lines in Croatia.
Postwar period of recovering Bosnia and Herzegovina has not appostrofided an idea of construction of Vareš–Banovići railway line as a priority. However, the occasional discussions on expert and political level about the extension of the new railway lines in Bosnia and Herzegovina and conections with the region included, among rest, railway line Vareš–Banovići, as well.
The post-war recovery of railways in Bosnia and Herzegovina was designed in three phases. The first phase involved the establishment of rail traffic on all lines. The second phase is to bring the railways in all segments (infrastructure, mobile capacities, services) on the level of the nineties. In the third phase is planned step forward in technological and organizational terms and one of the goals was the construction of new railway lines including the line Vareš- Banovići.

Fig. 1.
New railway lines in Bosnia and Herzegovina
Source: ŽFBH, 2006.

Figure 1 is a proposal for the construction of new railway lines in Bosnia and Herzegovina and the region in June 2006, including the drawn line and Vareš-Banovići.

2. Theses which emphasizes the construction of the railway Vareš-Banovići

2.1. Thesis 1: The strategic effects of linking the electricity sector in Bosnia and Herzegovina

Serious investment in Bosnia and Herzegovina with the support of foreign creditors in the last decade is mainly focused in infrastructure. International banks lend to construction of highways and overhaul and modernization of railways on the main lines. Regarding the other economic resources, foreign investors are only interested in the energy sector, and it is realistic to expect its intensive development in the coming decades[2].
Bosnia and Herzegovina is a manufacturer and exporter of electricity. Currently it has the resources to produce electricity whose installed capacity of about 4,000 MW. The three power utilities in Bosnia and Herzegovina, these resources are distributed according to the Table 1.

Table 1
Energy resources of Bosnia and Herzegovina

Company	Installed power	Structure
Elektroprivreda BiH	1600 MW	of which about 25% of the hydropower
Elektroprivreda RS	1600 MW	of which about 50% of the hydropower
Elektroprivreda HZHB	800 MW	total power from hydropower plants

In terms of production capacity of Elektroprivreda BiH, 25% of the installed power in hydro power plants on the Neretva River, and 75% in thermal power plants Kakanj and Tuzla as follows:

- Thermal power plant Tuzla 4 blocks of 715 MW,
- Thermal Power Plant Kakanj 3 blocks of 450 MW.

According to projected and contracted parameters of two new power plants of Elektroprivreda BiH should provide for about 800 MW of installed capacity, which will increase to 50% more installed capacity, as follows:

- Thermal power plant block VI of 450 MW,
- Thermal power plant Banovići 350 MW.

The aforementioned parameters of the power and importance electric-power sector for the entire economy of country impose certain considerations and emphasize the construction of the railway line Vareš-Banovići. The three thermal power plants of Elektroprivreda BiH (Tuzla, Kakanj and Banovići) with installed capacity of approximately 2,000 MW

[2] It was built power plant Stanari near Doboj. Block VI Power Plant Tuzla is contracted and expected its construction, and regarding the power plant Banovići the international tender has been completed and is expected to select a contractor. All these energy facilities financed and built the companes from China.

are located on the slopes of the mountain Konjuh and Zvijezda of which is done digging coal to generate electricity and that are geographically situated next to each other (divides them only river Krivaja), but these three thermal powers are in terms of communication each other very distant (about 230 km). From the technical and technological, logistic and many other reasons, these three plants should be connected by the shortest possible route. Since the work of these industrial giant unthinkable without quality railway communication it is logical that they should be linked by railway line with upper quality level than it is now. Here bellows are the results of a short analysis of comparison data are unambiguous:

1. Kakanj - Tuzla - Banovići about 230 km (currently, over Doboj),
2. Tuzla - Banovići - Kakanj about 130 km (over Vareš) - 100 km.

Bearing in mind that the current needs of Kakanj and Tuzla rail transports per year about 4 million tons of coal, it is expected that these needs after construction contracted plant (TPP Tuzla block VI and Banovići) increase by additional 3 million tons per year. The above statements, suggesting the need for a complete system connects by quality railway line and the shortest route is the logical lines Vareš-Banovići, which is about 100 km shorter than the existing railway lines via Doboj.

Fig. 2.
Linking electric power sector of Elektroprivreda BiH
Source: Authors

Figure 2 shows the map linking three thermal power plants by railway line Vareš-Banovići. This approach to track construction Vareš-Banovići, arising from the context of investment in the energy sector of Bosnia and Herzegovina, for updating the aforementioned reflection and discussion of the introductory part. In fact, such an important endeavors should gain regional significance because its implementation would offer new standards and opportunities in the field of transport.

2.2. Thesis 2: Strategic regional effects provided by connecting Sarajevo and Belgrade for three hours by train

Starting from the fact that the region of Southeast Europe permanently in the focus of events and discussions in the EU institutions and that in these discussions, generally uses the term reintegration of the Western Balkans, most often raises the issue of communication, the shortest and fastest connections between economic centers and capitals of these states. The idea of the seventies of the shortest a rail link between Belgrade and Sarajevo is partly already implemented by construction of the railway line Tuzla –Zvornik, and marginalised Vareš–Banovići railway line, which rounds off the project. Linking Živinice-Zvornik and Vareš-Banovići rail lines leads to the final goal and rail connections Belgrade - Sarajevo and ideas: “Belgrade-Sarajevo by train for three hours."

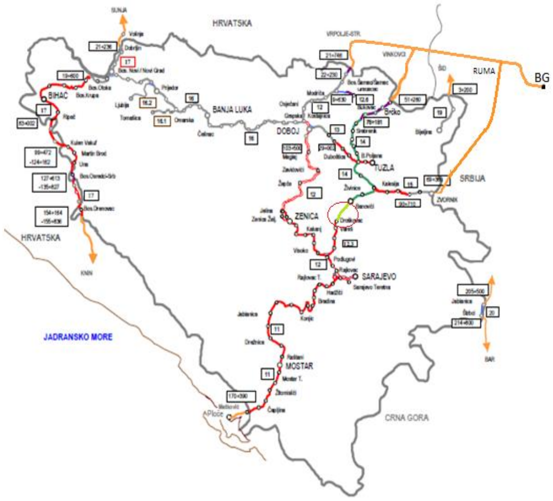

Fig. 3.
Railway network in BiH with connections Sarajevo – Belgrade
Source: ŽFBH, Authors

Very often there are discussions and analysis work on shortened travel time between Sarajevo and Tuzla, two of the largest commercial center in Bosnia and Herzegovina. The existing connnections by road (120 km) and by rail (270 km) are in very bad condition. On several occasions, on this direction were nominated different rail and road route, however shortest distance would be reached by construction of the railway line on the section of Vareš-Banovići. This complex project could become very important when get a regional character connecting Sarajevo-Belgrade by the shortest railway line and then continue to the Port of Ploče on the Adriatic Sea. According to the existing railway network (Figure 3). Currently, from Sarajevo to Tuzla region by rail comes through Doboj. The distances are shown in Table 2:

Table 2
Railway lines linking Sarajevo and Tuzla region

Railway lines	Total length
Sarajevo– Doboj - Tuzla	264 km
Sarajevo – Doboj - Banovići	283 km
Sarajevo – Vareš	53 km

From Sarajevo to Belgrade by train there are three existing railway lines and distances are shown in the following table:

Table 3
The total distance between Sarajevo and Belgrade

Current lines	Total length
Sarajevo – Doboj – Bos.Šamac – Vinkovci – Beograd	500 km
Sarajevo – Doboj – Brčko - Šid – Beograd	571 km
Sarajevo – Doboj – Zvornik – Beograd	524 km

In the case of construction of the new railway Vareš - Banovići, whose length is estimated at about 50 km distance to the railway lines would be shortened in the range of (130-180) km, as it shown in Table below:

Table 4
Estimates of total shortening the distance between Sarajevo and Belgrade

Railway line	km	Comparation	Shorter length for
Sarajevo – Vareš – Banovići	53+50	103 km/ 283km	180 km
Sarajevo – Vareš – Banovići – Tuzla	103+35	138 km/ 264km	126 km
Sarajevo – Vareš – Banovići – Zvornik	103+68	171 km/ 325km	154 km
Sarajevo – Vareš – Banovići – Zvornik – Beograd	171+99	370km/ 524km	154 km

The existing railway line Sarajevo-Tuzla via Doboj of 264 km would be shortened by 126 km and then it was 138 km and the shortest railway line Sarajevo-Belgrade over Doboj and Vinkovci than 500 km would be shortened by 130 km and reduced to 370 km. So, in the case of construction of the new railway Vareš-Banovići, a distance of approximately 50 km defining the shortest distance train for the section Sarajevo-Tuzla 138 km and Sarajevo-Belgrade 370 km. At the present stage of development of technical and technological solutions in the railway transport railway in the world defined as conventional, with speeds up to 160 km/h, and high-speed lines with over 200 km/h. The railway line Vareš-Banovići as part of the line Sarajevo-Belgrade would have the character of conventional tracks and it would be expected that with the repairs and electrification of the entire section it would be reached an average speed of 120 km/h in passenger traffic. Since in the eighties at the time the largest volume of passenger rail transport in BiH, the travel time on the section line Sarajevo-Belgrade were 4.5 to 5 hours, then travel time of three hours would be a new record and the historical success of the two countries and two railways.

2.3. Thesis 3: The strategic effects for the economy of Tuzla region and the respective gravitational area

Such an undertaking automatically entails reducing lines Sarajevo-Tuzla on a little longer than an hour travel time, which would be a historic step forward for the two regions and the whole of Bosnia and Herzegovina, reflecting to the railway line Sarajevo to Ploče[3]. By opening new lines of Banovići to Vareš achieved convergence of Tuzla economy to Sarajevo and Ploče Port for about 130 km. The economy and the population of Sarajevo and Tuzla are very connected to big economic systems in the Tuzla region[4], such as their businesses are based on rail transport through the Port of Ploče.

In the period up to 1992 on Ploče-Sarajevo railway line the freight volumes approximately were 4.5 to 5.0 mill.tonnes of goods per year. In the last 10 years will be transported about 50% of pre-war volumes, meaning approximately 2.2 to 2.5 million tonnes of goods per year. The 50% of all goods transported by rail in this direction, are goods for the economy in the Tuzla region. So that is still on that line for the needs of the economy in the Tuzla region by rail transport from 1.0 to 1.25 mill.tonnes of goods per year, although industrial plants operate with half the capacity. It is expected certainly increasing of the economic development in BiH in the future, and thus increasing the amount of goods transported by train in this direction. With the current parameters, and in the case of shortening the distances listed for about 130 km from Sarajevo to Tuzla, that would mean a saving of 156 mill.ntkm in transport by rail or saving Tuzla economy to transport goods of about 15 mill.KM annually. Return to the previous volume of transport, as the optimal needs of industries in Tuzla region, these values are doubled and the savings would amount to approximately of 30 mill.KM annually.

In the current situation financial parameters are not significant, but must not be ignored new benefits and opportunities in the regional integration that by this railway line could be opened. It is understood that the whole railway line in the length of 370 km were electrified and modernized. It opens up new possibilities for other rail routes that branch off the node Tuzla:

- Railway line Tuzla-Doboj-Banja Luka and further to the west. The overhaul, modernization and electrification of railway line of Zvornik to Ruma via Šabac which has a connection to Corridor X would increase a transport volume capacities and throughput, and would open new opportunities for the economy of the region,
- A new transport route Danube Port of Plčce Port (Danube - Adriatic),
- Shortens the distance railroad Brčko Port - Port of Ploče for approximately 130 km.

If this is the first step towards quality linking Belgrade with Sarajevo and (Tuzla and Sarajevo), then it is surely the second step of addressing mountain pass Ivan and extension to the Port of Ploče, which means connecting port of Brčko and the Danube to the Adriatic Sea by quality rail line through Sarajevo. This entire project would be a great resource of transit goods on Vc Corridor from the Port of Ploče for Hungary and other countries of Central Europe which could be the ultimate goal.

3. Analysis of the possible route of the railway line Vareš-Banovići

There are a number of documents that have dealt with this matter in the past. These are documents that were made for the needs of railways and some national institutions of Bosnia and Herzegovina. The above-mentioned documents offer several variants of the railway route Vareš-Banovići but everyone is a joint that needs to overcome two mountain ranges Konjuh and Zvijezda tunnels from approximately 4 and 8 kilometers in length, respectively. The height difference between Banovići and Vareš is approximately 460 m. Railway station in Vareš is located at 760m above sea level and Banovići at 300m. The route must pass through the valley of the river Krivaja and some of its tributaries and has to connect some places that are in this direction, such as Ribnica, Stjepin Han, Careva Ćuprija, Kamensko, Vijaka and others. In Figures bellow are presented proposed route of railway line Vareš-Banovići, with the longitudinal track profile:

[3] They've already done some studies on shortening the line Sarajevo-Ploče and avoided mountain pass Ivan Sedlo, but it should be the subject of another analysis. In this case calculates with an existing railway line Sarajevo-Ploče, a distance of about 200 km.

$$I = \frac{H}{L} = \frac{46.000}{50.000} = 9{,}2‰$$

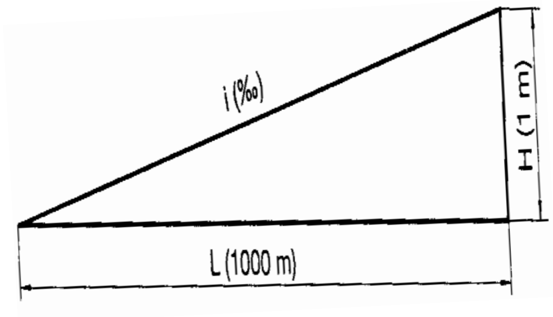

Fig. 5.
Longitudinal profile of track
Source: Authors

What is very important, but it is not subject to these considerations, are the natural, forest and mineral resources regions through which the railroad would passed. From the resources of the mountain Zvijezda for centuries exploited iron ore, followed by lead, zinc, barite, and various kinds of ornamental and building stone. On the slopes of the mountain Konjuh for years digging up coal and other minerals but it is certain that the ranges of these mountains are hidden and other, as yet unexplored mineral wealth enormous value. Forest areas of these regions are among the largest in Bosnia and Herzegovina. Although there are already good quality data on these nature resources, in the event that this project start implementing, it would be necessary to update these information. In the sence of the mobility the construction of this railway line would mean chance the development for people of the related area.

4. SWOT analysis of Vareš-Banovići railway line

Strategic planning of the new railway lines as a part of transport infrastructure should always be a function of the opening: individual mobility, the efficiency of the whole transport sector abd the integration in the transport network of the wider region. Strategic planning of railway network development must be done while respecting the principles of: (1) Burden the state budget, (2) Credited in gross domestic product, and (3) Stimulating effect on the growth of other industries.
The formation of the transport network on the principle of integrity and intermodal respecting subsidiary of conditions for sustainable development by defining the development goals for the dynamic program of infrastructure development with the main content:

- Objectives (strategic and structural),
- Origins (legitimate objectives at the level of international projects, regional level, the European level and the state level),
- The basic elements (valorization of the current situation, the capacity utilization estimate trends in demand),

- The proposal (transport network, traffic-technical characteristics, priorities - the dynamics, the cost of investment, exports),
- The implementation (preparation of project documentation, financing, coordination of relevant departments, responsibility),
- The implementation of the strategic goals of transport development is dependent on the external factors and is sensitive to changes in other economic and governmental departments (SWOT analysis).

Below is a SWOT analysis as a starting point in defining the strategic guidelines for the implementation of the railway line Vareš-Banovići.

Table 5
SWOT analiza projekta željezničke pruge Vareš-Banovići

STRENGHTS	WEAKNEES
▪ Approaching Tuzla and Sarajevo cconomy to the Port area for about 130 km ▪ Shortest rail link between Sarajevo and Belgrade ▪ Mass and variety of transportation ▪ Transit rail route ▪ A high level of safety of transportation ▪ Greater energy efficiency with possibilities the use of national energy resources ▪ Low external costs ▪ Unconditioned climates ▪ Low transport costs ▪ Lacing system te tuzla Banovići- Kakanj	▪ Future railway route in length of about 50 km is very demanding and complicated int erms of construction ▪ It is necessary to build two large tunnels and several very demanding bridges ▪ Fragmentation of infrastructure management ▪ Unsatisfactory level of maintenance capacity ▪ Technological obsolescence of mobile capacity ▪ Lack of management practices ▪ Undeveloped marketing approach and market orientation railways ▪ Accumulated losses and žfbh ▪ Limited new investment projects opportunities ▪ Low productivity
OPPORTUNITIES	**TREATHS**
▪ Intensive integration into regional transport flows and interoperability ▪ Shortening the distance by rail: brčko port - Port of Ploce For approximately 130 km ▪ Opening of a new transport route danube ports - port Ploče (danube - adriatic) ▪ Opening up new opportunities for rail routes Tuzla - Doboj Banja Luka and further to the west and from Zvornik to Ruma via Šabac ▪ Development of the timber industry and mining ▪ Development of tourism ▪ Increasing in gross domestic product in bih ▪ Increased demand on rail traffic market ▪ Creation of mechanisms for sustainable financing of the railway infrastructure ▪ Employment of local labor force and building operations	▪ Inconsistent strategy development of the transport system ▪ Lack of long-term national development strategy for railwa ▪ Insufficient financing of rail infrastructure ▪ Slow implementation of rail investment projects ▪ Unsustainable financial architecture of rail sector ▪ Non-realization of financial consolidation and stabilization ▪ Underdeveloped contemporary models of public-private financing of rail infrastructure ▪ Insufficient attracting foreign investors and the lack of so-called healthy investment climate

5. Railway line Vareš-Banovići in the European context of meagement of large infrastructure projects

The main Trans-European transport network (TEN-T) objectives are: (1) removing bottlenecks, (2) the construction of the missing cross-border links, (3) promotion of multi-modal integration and interoperability, (4) integration of rail freight corridors, (5) promoting environmentally clean fuel and other innovative transport solutions, (5) the use of modern telematics applications for the efficient use of infrastructure, (6) the integration of urban areas in the TEN-T, and (7) increasing of safety level.

An efficient European transport network is essential to ensure our economic competitiveness. Large infrastructure project are are an important link for European transport and on a higher level contribute to economic and social sustainable growth of our society. Large infrastructure project must be conceived, managed and operated as an integrated whole, focussing not only on the completion of a physical project as an end in itself, but also on stakeholders involved. Key success factor in the organisation and management of large infrastructure projects is a dual focus between 'control' and 'interaction'. Control focuses on the internal world of the project and the project team, requiring adequate (processes for) planning, risk management, financial engineering and scope definition. Interaction is related to the external world of society. Two elements are essential: an open culture and the ability to adapt to changes within the context.

One of the key objectives is to link organisations and stakeholders responsible for developing and introducing new transport inftastructure projects in relation with the new Europena transport policy. This should be done both locally and internationally in Europe for the dissemination of experience and knowledge. The NETLIPSE (2008) has identified five groups of organisations participating in large infrastructure projects:

1. European Commission ,
2. public and private funders, World Bank, European Investment Bank, European Bank for Reconstruction and Development,
3. Project delivery organisations,
4. Parent organisations,
5. Principals / sponsors.

For each of these groups three basic functionalities have been determined. The functionality applies to every organisation but may apply on different levels and with different effects:

1. Project financing order to: judge if a proposed project should be (co-)financed by the EC, national ministries, private funders, World Bank, EIB, EBRD and others,
2. Benchmark, monitoring and project management in order to: (1) monitor the progress of financed projects, (2) evaluate projects (both ex-ante and ex-post), (3) measure the performance of the project delivery organisation with a validated instrument/norm, (4) to enable the comparison of the performance of the project delivery organization to the performance of the project delivery organisations of other large infrastructure projects thereby helping to identify areas for improvement, and (5) to stimulate the successful execution of financed projects,
3. Knowledge management in order to: (1) help to draw experiences – in the form of 'best practices' – from inception through realisation of a project in order to improve the quality of a project delivery organisation; (2) to collect, disseminate and transfer best practises to future project delivery organisations.

Most usual success criteria used assumed that the main criteria for success for projects were the so-called golden triangle of time, finance and required quality. However, the issue of project success turned out to be far more subtle than this. Large investment project management conceptual model developed by NETLIPSE (2008), presented in Figure bellow, links three main aspects:

1. the organisational and managerial factors (project success factors) within the project delivery organization,
2. the project results (critical success criteria), and
3. context of the infrastructure project.

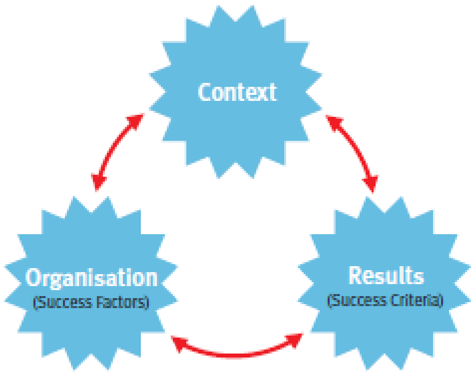

Fig. 6.
Large investment project management conceptual model
Source: NETLIPSE, 2008.

Risk management should also focus on opportunities that often are the result of interaction withstakeholders. The new process uses experiences from former projects to estimatecosts of new projects. With the aid of the Monte Carlo simulation method, best, worst and realistic scenarios can be calculated.

6. Conclusion

The construction of the railway Vareš-Banovići is occasionally actual and very intriguing subject. It offers great opportunities but also opens up a number of issues. Through elaboration is presented to the benefits that it could bring can be viewed from several aspects. First of all it is a binding three thermal power plants from the system EPBIH railway line will be shorter by about 100 km from the present. Then, binding of economy Tuzla and Sarajevo region and the convergence of Tuzla industrial capacity Ploče Port for about 130 km, with the order to make significant savings. It is especially important to note the regional character of the project, approaching Sarajevo and Belgrade for about 150 km, ie, shortening the travel time by train between Sarajevo-Belgrade for three hours.
However, it is clear that the future railway route in length of about 50 km is very demanding and complicated in construction and the execution terms. The height difference between Banovići and Vareš is approximately 460 m. It is

necessary to build two large tunnels and several bridges very demanding. In a time of advanced technologies and high scientific achievements certainly is that these obstacles can be easily overcomed. Also, it should be noted that the available studies, reports and other documents have been made in seventies and that are riped to check and control the application of modern technologies and new technical solutions. There was a change in the overall environment on the railway route. The changed geo-political conditions, because now is the decision of this type largely yields and with the consent of local governments, such as in the present case, Zenica-Doboj and Tuzla Canton. Then, economic conditions (inactivity) on the railway route area dictated by the launch of new investment because some important economic entities have been closed, especially in the municipality of Vareš. In the end, there was a change in the demographic structure of the population, as many as a result of the war displaced. The condition of return and sustainable residue of the region is launching economy activities and employment. The construction of the railway line Vareš-Banovići would represent a significant opportunity for employment of local labor force. In any case, should take advantage of a favorable climate in the EU, where they are now very current issues of reintegration of the Western Balkans and to prepare them for entry into the EU and run this and similar development projects. A large project like this should arouse the interest of relevant stakeholders, encouraged the economy of he whole country and region. Theses presented are actually a step forward to scientific thought in order to provide further scientific support needed for this project.

SESSION 8: ROAD TRAFFIC AND TRANSPORT RESEARCH - ENVIRONMENTAL PROTECTION AND EFFECTIVENESS

ACIDIFYING EMISSIONS INCREASING DUE TO ROAD TRAFFIC CONGESTION

Eugen Rosca[1], Mihaela Popa[2], Vasile Dragu[3], Dorinela Costescu[4], Aura Rusca[5], Stefan Burciu[6]
[1,2,3,4,5,6] *University Politehnica of Bucharest, Faculty of Transport, Transports, Bucharest, Romania*

Abstract: The road transport sector is one of the greatest contributors to acidifying emissions, especially in NOx emission. Despite the overall reduction trend in the last decade, EU as a whole and other member states failed to meet the emission ceilings set by the EU directive. Due to the harmful potential (acid deposition, eutrophication and human health risk) a special attention is required in transport sensitive areas where the land use individualities, transport network features and spatial/temporal human activities distribution generate specific traffic patterns and often congestion. Following the latest European Environment Agency guidelines, the paper presents a methodology for assessing acidifying emissions by integrating GIS data, road traffic micro-simulation and emission factors. Individual vehicle driving is reproduced and exhaust emissions computed based on average speed, mileage, fuel, engine capacity and standards. The case-study done on Prahova Valley (Carpathians) outlines the way the road congestion influences the emissions at local level, comparing to the Europe average levels.

Keywords: acidifying emissions, traffic congestion, transport sensitive area.

1. Introduction

The Göteborg Protocol under the 1979 Convention on Long-range Transboundary Air Pollution (LRTAP Convention) and the EU Directive on National Emission Ceilings (NECD - 2001/81/EC) set emission ceilings for the acidifying pollutants that states should have met by 2010. The NECD, which is more restrictive, is now part of the implementation of the Thematic Strategy on Air Pollution, and a revised directive should set emission ceilings to be respected by 2020. Within most European Environment Agency (EEA) member states (20 of 32), emissions of the three acidifying pollutants (SO_2, NO_x and NH_3) have decreased significantly between 1990 and 2012 (European Environmental Agency, 2014). The EU-28 met its overall target to reduce emissions of SO_2 and NH3 as specified by the NECD, while just two countries (Finland and Spain) exceeded the ammonia limits. However, based on preliminary data, eleven of the individual member states, and the EU as a whole, missed their NECD 2010 emission ceilings for NOx (European Environmental Agency, 2012a).

Among the economic sectors, the road transport is the main contributor in the total EU-27 nitrogen oxides emission (38.4%), and has lower contribution to ammonia (1.9%) and sulphur dioxide (0.2%) emissions. The NOx exceedance is partially because the sector has grown more than anticipated and partially because vehicle emission standards have not always provided the expected level of NOx reductions.

Although many European states meet their acidifying emission ceilings, a special attention should be paid to transport sensitive areas (e.g. urban and high industrialized areas, mountain corridors, coastal zones). In such areas, the air pollution at local or regional level has negative impact because of high pollutants concentration due to specific climate conditions, canyon effect or atmospheric inversion process which allow the capture of emissions on inferior air layers, soil and water (Whiteman and McKee, 1978; Hobbs, 2000; Wallace and Kanaroglou, 2009; Taseikoa, et al., 2009; Devasthale and Thomas, 2012). Since 2002, NOx average annual mean concentrations at urban background sites have fallen by just 9%, while the reported NOX emissions for the EU-27 decreased by 23% (European Environmental Agency, 2014). Bičárová (2008), Lieb, et al. (2009), Enei and Vendetti (2009), Monigl, et al. (2009), investigate the transport related impacts in different European transport sensitive areas (urban, mountainous or coastal zones). Using macro-scale models, they compare vehicle exhaust emissions in business as usual scenario with scenarios implementing different policy measures (e.g. limited number of crossing heavy-duty vehicles, taxation access, and improved fuel usage). Janic and Jovanović (2012), estimate the positive environmental effects from rail/road substitution in the Trans-European transport corridors.

Acidifying emissions cause damage to ecosystems, human health, buildings, cultural/historical monuments and materials (corrosion). The effects associated with each pollutant depend on its potential to acidify and the properties of the ecosystems and materials. Nitrogen oxides, ammonia and sulphur dioxide contribute to acid deposition and eutrophication which directly disturb soil and water (European Environmental Agency, 2012b). The acid deposition leads to adverse effects on aquatic ecosystems and damage to crops, forests and other vegetation. Nevertheless, the areas subject to acid deposition beyond critical loads in 2010 still exceed 10% of the EEA-32 natural ecosystems. Eutrophication is responsible for decreased biodiversity, changes in species composition and dominance, and toxicity effects. Only in five of the EEA-32 member states the area at risk is estimated to be lower than 50%. NO2 is associated with direct adverse effects on human health, as at high concentrations it can cause inflammation of the airways. Indirectly, the three substances contribute to the formation of secondary particulate aerosols and tropospheric ozone in the atmosphere which have harmful potential. Schwela and Zali (1999), Krzyzanowski, et al. (2005), thoroughly investigate the epidemiological studies of human health effects arising from road traffic air pollution. Pye et al. (2005) and Holland et al. (2011) provide costs-benefits analysis including health and non-health effects generated by the revision of the Göteborg Protocol and the EU Directive on National Emission Ceilings.

2. Assessing the road traffic acidifying emissions through computer simulation

Across Europe, the most pertinent tools for estimating road transport emission that have been used are CORINAIR (Eggleston et al. 1992), DRIVE (Jost, et al. 1992), COST 319 (Joumard, 2009), HBEFA (Hausberger et al. 2009), TREMOVE (Ceuster et al., 2007), COPERT 4 (Ntziachristos et al., 2009). The European Environment Agency issued the Emission Inventory Guidebook (2009) that covers a high range of exhaust emissions (acidifying substances, greenhouse gases, ozone-precursors, particulate matters, heavy metals, toxic and carcinogenic substances). The guidebook, following the Guidelines for Reporting Emission Data under the Convention on Long-range Transboundary Air Pollution and the EU National Emission Ceilings Directive, provides concise guidance on how to compile an atmospheric emissions inventory at various degrees of sophistication. The EEA guidelines use three approaches, according to the level of data availability:

- Tier 1 approach uses fuel as activity indicator in combination with fuel-specific emission factors, according to the vehicles classification (passenger car – PC, light-duty vehicles – LDV, heavy-duty vehicles – HDV, busses and coaches, motorcycles). The method provides country-specific upper and lower values for all EU nations, but should only be used in the absence of traffic detailed information. It creates a macroscopic view of the emissions inventory,
- Tier 2 approach could be used when vehicle x km statistics per vehicle technology are available. It considers the fuel used by different vehicles categories and their emission standards. The method considers a mesoscopic map of the emission inventory,
- Tier 3 approach calculates exhaust emissions using a combination of technical data (e.g. engine capacity, type of fuel, emission standard) with activity data (mileage and average speed). The detailed Tier 3 approach allows a microscopic view for exhaust emissions and a more accurate evaluation for small areas (e.g. cities, road sectors).

The methodology described in the Emission Inventory Guidebook is now part of the COPERT 4 software – used to calculate air pollutant emissions from road transport in the national emission inventories, and also in CORINAIR – providing date at the county/department level (NUTS level 3).
Using the principles described in EEA guidelines, the following proposed technique for a detailed evaluation of the acidifying emissions combines field recorded data, traffic micro-simulation using VISSIM software and emission factors estimated through Tier 3 approach. The flow chart for the acidifying emissions assessment is depicted in Figure 1.

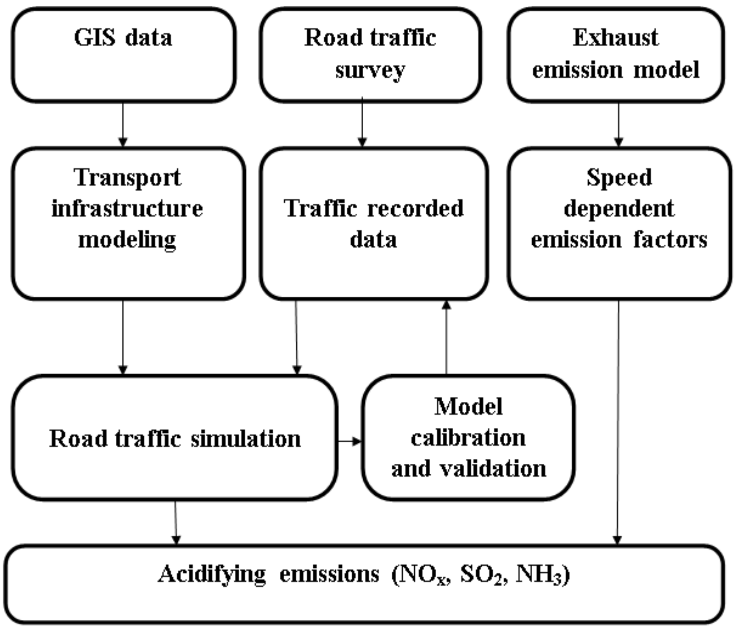

Fig. 1.
Acidifying emissions assessment
Source: original

2.1. Transport infrastructure modeling

The Geographic Information Systems (GIS) provide scalable geographic maps and detailed transport network data used further into traffic simulation programs. Based on real world coordinates, the transport network is modeled in terms of links, lanes, intersections, roundabouts, gradient, public transport terminals/stations, speed limit areas, priority rules, signaling systems.

2.2. Transport infrastructure modeling

The module considers traffic survey data obtained in the field. The vehicles are recorded separately by type (passenger car, LDH, HDV, bus/coach, motorcycle). Traffic flow variations are also observed. The daily peak-hours, weekends or seasonal variations influence the exhaust emissions due to changes in the vehicle driving cycles. The next classification of the vehicles is done according to their fuel type (gasoline, diesel, LPG, CNG, hybrids), technology/standards (pre Euro, Euro 1-5) and engine capacity. Other traffic participants (pedestrians, cyclists) have to be included as long as they interact with the road traffic flows.

2.3. Road traffic simulation

The traffic recorded data and the transport infrastructure model represent inputs for the traffic simulation software. The main advantage when using the computer traffic simulation is to reduce the amount of measurements, which have to be performed in the field. Also the simulation models have the ability to evaluate the future traffic scenarios based on various traffic management schemes. Models describing how to integrate traffic micro-simulation with different emission models are provided in (Xia and Shao, 2005), (Tate, Bell and Liu, 2005), (Boulter and McCrae, 2007), (Panis, Broekx, and Liu, 2006) and (Jayaratne et al., 2009). Traffic simulation allows obtaining the output data that are further used in the exhaust emission assessment:

- The vehicle ID,
- The vehicle type and its technical characteristics (fuel used, engine capacity, emissions standard),
- The mean speed of each vehicle along the route,
- The car mileage of each vehicle.

2.4. Model calibration and validation

The validation process concludes whether the simulation model is close enough to the real system. The validation of the model is usually an iterative process that calibrates the model parameters until the accuracy of the model becomes acceptable (Barceló, 2010) and (Cvitanić, et al 2012). The VISSIM software implements the psycho-physical car-following model developed by Wiedemann (1974). A manual calibration process is used, by varying two parameters describing the car following model:

- Standstill distance (1.0-1.6 m),
- Headway time (0.8-1.2 s).

The validation is achieved by minimizing the mean square between the observed and the simulated mean speed of the vehicles and by computing the GEH statistic that compares the real and the modeled traffic volume:

$$GEH = \sqrt{\frac{2(M-R)^2}{M+R}} \tag{1}$$

Where; *M*: the hourly modeled traffic volume, *R:* the real (counted) one. A *GEH* value less than 5 is considered a good match.

2.5. Emission factors

NO_x and NH_3 are directly estimated, based on the specific emission factors covering different traffic situation and engine characteristics, while SO_2 emissions are estimated based on the fuel consumption.

2.5.1. Nitrogen oxides (NO_x) emission

EEA (2009) offers generic functions for estimating the nitrous oxides emissions in relation to the vehicle type, fuel, engine capacity, engine emission standards and vehicle mean speed. These functions having exponential, power, logarithmical, polynomial form or a combination of them have been estimated through statistical analysis of the empirical data, providing for most of them coefficients of determination higher than 0.85. For instance, the emission factors for Euro 1 and later gasoline passenger cars have the generic function:

$$e_{Euro1,G}^{NOx} = \frac{a + c \times v + e \times v^2}{a + b \times v + d \times v^2} \tag{2}$$

Where; $e_{Euro1,G}^{NOx}$: the NO_x emission factor for gasoline Euro 1vehicles [g/km], v : vehicle mean speed [km/h], $a-e$: calibration coefficients specific to engine capacity.

2.5.2. Sulphur dioxide (SO_2) emission

The SO_2 emission factor is computed based on fuel consumption, assuming that all sulphur in the fuel is transformed completely into dioxide:

$$e_{k,m}^{SO_2} = 2 \times k_{S,m} \times FC_{k,m} \tag{3}$$

Where; $e_{k,m}^{SO_2}$: the SO_2 emission factor for vehicles with engine technology *k* and fuel type *m* [g/km], $k_{S,m}$: weight-related sulphur content in fuel of type *m*, $FC_{k,m}$: fuel consumption [g/km].
The fuel consumption is highly sensitive to the average speed and has different generic function according to the technical characteristics of the vehicles and fuel (EEA, 2009). The weight-related sulphur content is dependent on fuel type and production technology (Table 1).

Table 1
Fuel weight-related sulphur content in Romania

Fuel	Market share	Sulphur content [mg/kg]			
		Min.	Max.	Mean	Limit
Gasoline (95≤RON*<98)	16.45%	4	14	8	10
Gasoline (RON≥98)	10.24%	3	22	8	10
Diesel	73.31%	2	294	12	10

** RON – research octane number*
Source: Romanian Transport Ministry – Fuel Quality Monitoring Report 2010

2.5.3. Ammonia (NH_3) emission

The NH_3 emission factors are calculated according to:

$$e_{k,m,r}^{NH_3} = [a \times Mileage + b] \times EF_{base} \tag{4}$$

Where; $e_{k,m,r}^{NH_3}$: the NH_3 emission factor for vehicles with engine technology *k,* fuel type *m* driving on road type *r* [mg/km], $Mileage$: vehicle mileage [km], EF_{base}: base emission factor [mg/km], *a*, *b*: calibration coefficients.
The average mileages for each country and vehicle category are available on COPERT 4. The NH_3 base emission factors are not strongly dependent on vehicle average speed as NO_x and SO_2 emissions factors are.

2.6. SO_2 equivalence

The acidifying emissions can be aggregated into SO_2 equivalent taking into consideration the potential acidification equivalent (PAE).

Table 2
Potential acidification equivalent (PAE)

Emission	Potential acidification equivalent
Sulphur dioxide SO_2	1
Nitrogen oxides NO_x	0.7
Ammonia NH_3	1.88

Source: Intergovernmental Panel on Climate Change – IPCC

3. Case study. Assessing the acidifying emissions on Prahova Valley

The route along Prahova Valley, situated in the Meridional Carpathians, is one of the most transited routes connecting the southern and the central part of Romania. The route passes alongside the Bucegi Massif that is classified as a type B site (medium influence environment) by the European Network of Protected Areas – Natura 2000. The assessment of the acidifying emissions is done in an area delimited by two important mountain resorts (Sinaia and Bușteni), where due to the transport infrastructure (single lanes, intersections, dense pedestrian crossings) and the traffic non-uniformities, the road congestion often occurs, reducing the level of performance of the network and increasing the car exhaust emissions (Figure 2).

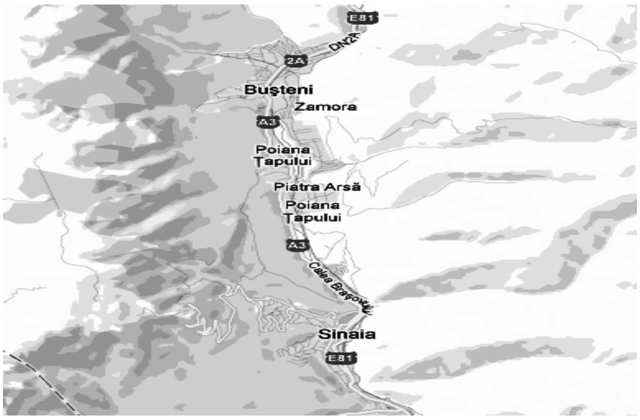

Fig. 2.
Prahova Valley
Source: Google Maps

The GIS transport infrastructure layout is completed by the traffic rules (vehicles speed limit, priority rules in intersections and pedestrian crossings) and by the public transport elements (stations placement, stop times distribution). The traffic flows are recorded separately by vehicles type: passenger car (PC), light-duty vehicle (LDV), heavy-duty vehicle (HDV), bus/coach (BC). The data are differentiated by the weekdays and weekends, outlining the traffic patterns according to the socio-economic activities cycle and the leisure-time travels (Holden, 2007). The average traffic flows (cumulative both ways) are shown in Figure 3.

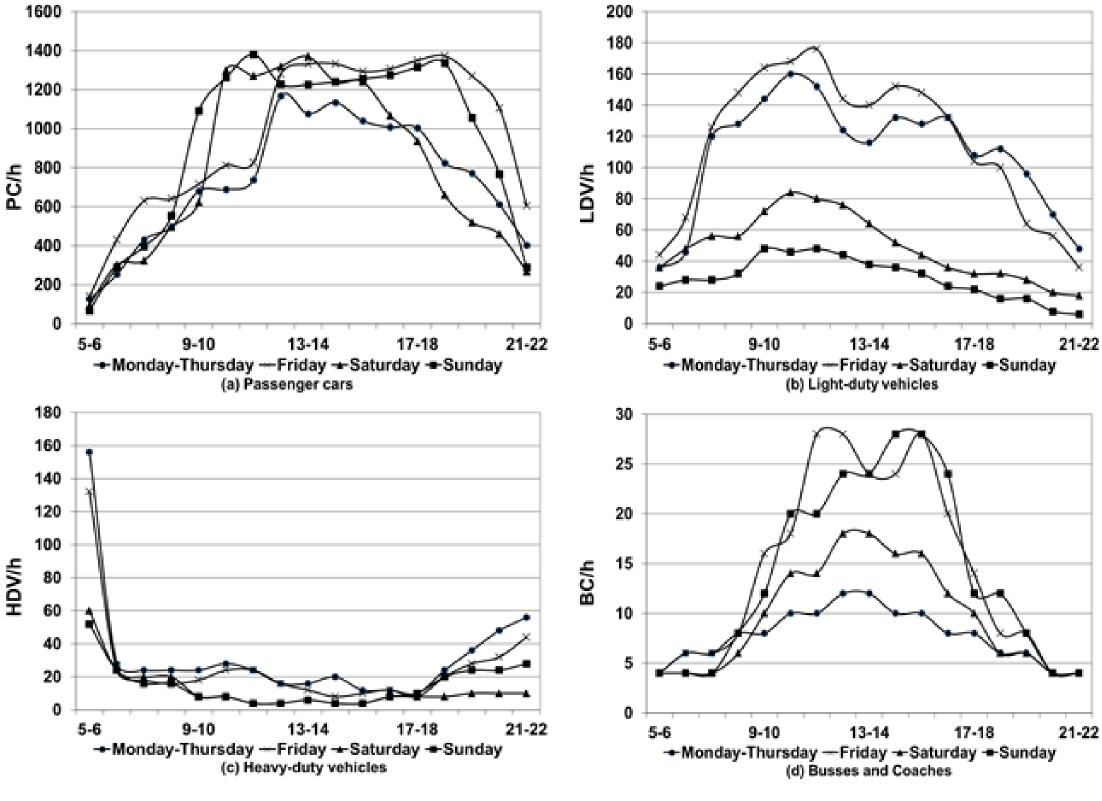

Fig. 3.
Average road traffic flows
Source: Original

The structure of the vehicles flow according to their fuel type and technology/emission standards is shown in Figure 4.

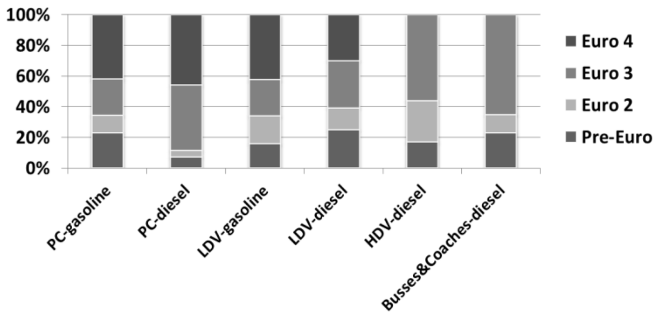

Fig. 4.
Statistical structure of the vehicles flow
Source: Original

The traffic simulation outputs have been obtained by hourly time intervals and by weekdays/weekend. Each vehicle entering the simulation process has allocated individual ID number and characteristics concerning its type, fuel, engine capacity, emissions standard and maximum speed allowed. The plot of the average speed to the traffic flow volume resulting from simulation is shown in Figure 5. The total traffic flow volume is expressed in equivalent passenger car units (PCU) using the equivalent factors proposed by Hobbs (1979).

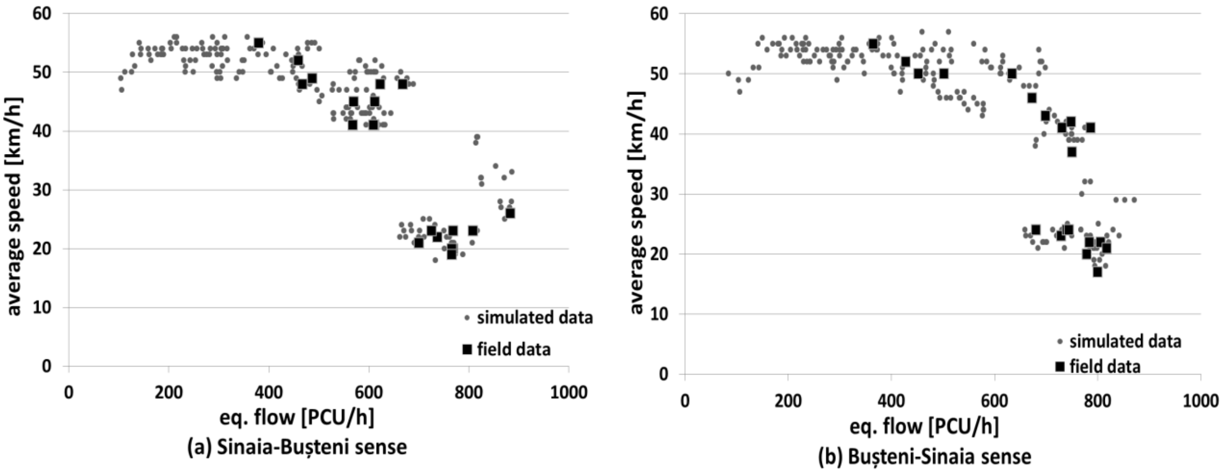

Fig. 5.
Traffic volume vs. average speed
Source: Original

The minimum mean square between the observed and the simulated average speed is obtained for a standstill distance of 1.15m and a headway time of 1.1s. The corresponding GEH statistic takes values between 1.24 and 3.79. The traffic situation creates specific congested phases characterized by a moving synchronized flow pattern that turns during some periods to a moving jam phase. The congestion appears on a single way on Friday and Sunday and on both ways on Saturday.
Following the assessment methodology described in the paragraph 2, the average equivalent SO_2 emission per unit of distance and time and by day of week is depicted in Figure 6.

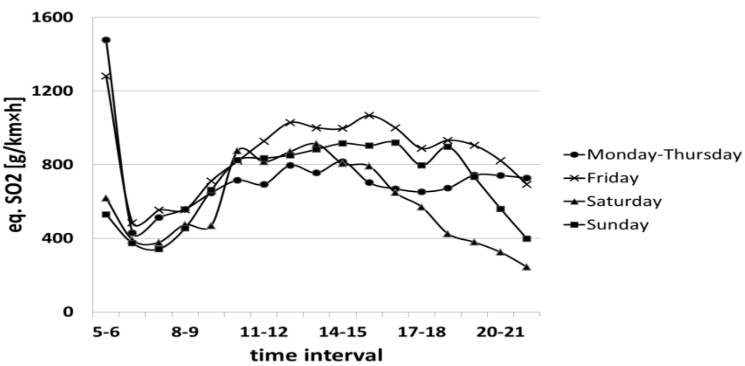

Fig. 6.
Equivalent SO_2 emission
Source: Original

Analyzing the equivalent SO_2 emission in Figure 6, some remarks are issuing:

- The morning emissions are greater during the weekdays due to the heavy-duty vehicles circulation. The HDVs are restricted to circulate on Prahova Valley during 06:00-22:00, unless a special infrastructure access fee is paid,
- The mid-day and the afternoon emissions are highly raised during weekends, due to increase in car traffic volume and the resulting decrease of the speed. As depicted also in Figure 6, congestion occurs during these time intervals of the weekends. The equivalent SO2 emission is 12.8-51.9% higher compared to the same time intervals of the weekdays.
-

The average NO_x emissions for the statistical predominant passenger cars (Euro 4) are depicted in Figure 7.

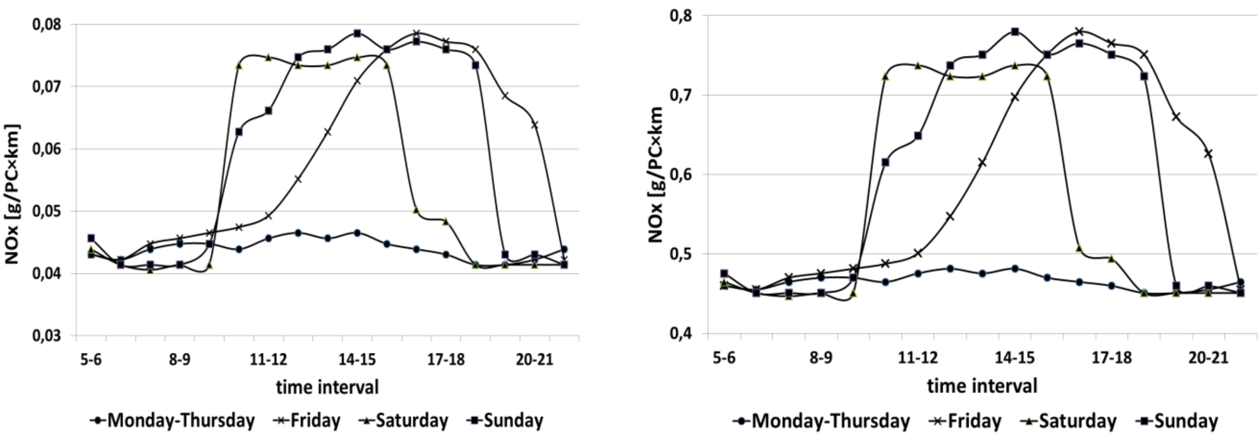

Fig. 7.
Average NO_x emission for Euro 4 passenger cars
Source: Original

During the weekdays and the out-of-peak time intervals of the weekends, the NO_x average emissions for Euro 4 passenger cars are below to the average value recorded at European level – 0.064 g/PCGasoline×km and respectively 0.553 g/PCDiesel×km (2011). This is specific to the free flow or the unconstrained car following flow patterns. During congested periods, the average passenger car emission increases up to 21.7% for gasoline cars and 40.9% for diesel cars.

4. Discussion

The weekend leisure-time and the business tourism are among the most responsible human activities for road traffic congestion and therefore for the growth in vehicle exhaust emissions along Prahova Valley. The rising of car ownership and the land use policies allowing the spread of the residential areas in mountain resorts are translated into an intensive passenger car use in the areas. Most of the new residential areas and the tourist accommodation facilities are developed in zones with feeble or non-existing public transport. At the same time, the modal shift is not well encouraged through national or regional actions towards more efficient transport means. While the main attracted passenger flows come from the great cities in the South region (Bucharest, Ploieşti) or Braşov county, the rail connection among them experience only one intercity train and four express trains/day, but most of them being long-ride trains, are often crowded and not suitable for leisure journeys to Prahova Valley. The decay rail infrastructure and the delay of investments make the journey time excessive by train (at most an average speed of 55km/h by the fastest trains). Due to the rail tickets price, the car journey becomes more attractive at an occupancy rate of 2.5persons/car. The seasonal "snow-trains" can alleviate the problem only on short period during ski season, but the services offered are not at high standards (insufficient space for equipment, poor frequency). No rhythmic train timetable is offered at local level between the mountain resorts. The green consumerism at local level that supports more friendly ways of traveling is also ignored. The decisions of the local authorities regarding the infrastructures do not observe the environmental governance and allowed the spread of the road into the alpine zone and the access of cars up to the hills. No limitations are also for the use of all-terrain vehicles. Developing positive values and green attitudes of individuals are necessary for achieving sustainable mobility in the area.

5. Conclusion

The two European conventions (Alpine and Carpathian Convention) urge for a balance between mobility and environment measures in mountain areas. Integrating transport demand management, market-based measures, land use planning, traffic coordination and education for green attitudes could accomplish this target. The coming into force EuroVignette 2011/76 EU Directive for road transport provides special amendments for transit through mountain areas, allowing the member states to increase the user charges or the tolls rates and to apply double coefficients for computing air and noise pollution. The revenue generated from the mark-up must be invested in transport projects contributing directly to the alleviation of the congestion or environmental damage and which are located in the same corridor as the road section on which the mark-up is applied.

THE INFLUENCE OF DRIVERS' BEHAVIOR AT TRAFFIC LIGHT INTERSECTIONS ON TRAFFIC PARAMETERS AND EMISSIONS

Daniel Kubek[1], Paweł Więcek[2], Dariusz Grzesica[3]
[1,2,3] Institute of Construction and Transportation Engineering & Management, Transport Section, Cracow University of Technology, Cracow, Poland

Abstract: One of the most important issue affecting road safety and reducing the negative impact of vehicles on the environment is identification of the level of emission of harmful compounds into the atmosphere as a result of driver response to events that occur on traffic light intersections. The exhaust emissions will be assigned on the basis of the microscopic traffic simulation model. It uses the driver's reaction time as a parameter related to the drivers behavior. The work will take into account the response time of the move, the response time at a standstill and the response time to traffic lights. The location of the intersection and type of lanes have an impact on the formation of values of these parameters. On the basis of selected conditions the values of emissions of CO2, NOx and PM will be assigned using traffic simulator AIMSUN 8.1. It will also identify the influence of drivers reaction on the traffic parameters.

Keywords: microskopic similation, drivers behaviors, exhaust emission.

1. Introduction

The driver's reaction time is a parameter, directly affecting the safety of road traffic. This parameter can be defined as the period of time counted from the moment the event occurs until the driver can take actions aimed at avoiding the adverse consequences of its occurrence. This is one of the main factors discussed in different road accidents. It is estimated that around 70% of road accidents in Poland is the result of the wrong actions of the driver (Kubek et al., 2014). In this regard, justified is research in the field of driver behavior on the road or intersection.
Actions taken by the driver in traffic situations are characterized by certain individual and various actions which depend on the following factors:

- efficiency of the central nervous system,
- state of mental and physical driver's features,
- situational conditions,
- drivers' experience,
- self-determined action (Bąk and Bąk-Gajda, 2013).

The driver reaction time includes many components, derived directly from him, as well as conditions on the road. They affect the permanent personal characteristics of the driver including age, change the psycho-physical condition, type of road situation, fatigue, biometeorological conditions, noise and alcohol (Stefański, 2008).
A contemporary issue has significant importance to improve road safety and reduce the negative impact of vehicles on the environment is to identify the level of harmful emissions into the atmosphere through the vehicle exhaust. In general it as a result of driver response to events occurring at the intersection. This phenomenon is especially important in Krakow, which belongs to the group of cities with the highest levels of air pollution in Poland and Europe. Except of industry and other of economy sectors the traffic in Krakow, is responsible for a major source of toxic emissions in the atmosphere. These compounds are very dangerous for human health, especially for people living in close proximity to busy traffic arteries. The most dangerous to humans compounds emitted by means of road transport are mainly nitrogen oxides, benzene, carbon, volatile organic compounds (VOC), and also very harmful to your health particulate matter (PM) (Kubek et al., 2014). Mixtures of these contaminants tend to change over time and space, depending on a number of features, such as close proximity of the road, the type and age of the vehicle, traffic patterns, and the presence of other sources of contamination. Short or long term exposure to these compounds in the air, can lead to very adverse health effects immediately or in later years, in the form of the respiratory, nervous and cardiovascular system diseases, as well as cancerous changes. According to measurements made by the WHO vehicles still have a large share in the emission of toxic compounds (Krzyżanowski et al., 2005).
One of the components affecting the emission of harmful substances into the atmosphere is a driver's reaction time at the traffic light intersection. The conducted regression analysis revealed the influence of road traffic factors on the level of driver's reaction time. They reached statistical significance influence level, although the dependent variable was explained in 32% -48% and the key aspects like intersection location, moment of the first car entering the intersection, participation in the movement of heavy vehicles, the position of the intersection and the distance of stop line to traffic light have a great impact (Chodur and Ostrowski, 2012). This study address the issue of harmful compounds emissions in a form of car exhaust as a result of driver response to the traffic light intersection in Krakow. Within the analysis the motion parameters like i.e.: the sum of the intensity of vehicles, average queue length, the sum of the number of stops and average delay were used.

2. State of research

The above issues have been the subject of research for many scientists from the country and abroad. The aspect of driver behavior in motion, affects, directly or indirectly, on the level of congestion as well as the level of safety on the road. This is evidenced by the results of the studies presented in numerous scientific research. Foreign authors often classify the study of driver's behavior indicating several subgroups: analysis of the vehicles behavior moving in a convoy, one after another, response of drivers during lane changing, during overtaking maneuver and reactions on traffic light changing at the intersection. In the case of the first three areas, the interesting solutions simulating reaction time and behaviors with the use of artificial neural networks, are presented in the works (Ghaffari et al., 2012; Khodayari et al., 2010; Yan et al., 2015). In addition, the work (Jurecki and Stańczyk, 2011) shows the popular methods of determining the drivers reaction time in the after-crush situations, together with the results of the research.
According to this work, the most crucial and valuable are results and conclusions arising from previous studies regarding to the analysis of the drivers reaction time for traffic light change at the intersection. The analysis of literature shows that studies considering driver behavior at the junction with traffic lights, can be divided into two main groups: studies in the computer simulator and the measurement at intersections (Green, 2000). An important observation arising from the work is the fact that response time reaction to changing light are shorter than those measured in reality. This is due to the simplified visualization, the smaller field of view, shallower depth of space, which have to be dealt with in the simulator. In this area a two situations can be highlighted, in which the driver's reaction time is measured. First is the moment of displaying of yellow light, before the appearance of red light and the second is time respond to a green light appearance. Research referring to the first of the above situations are presented, in particular, in (Goh and Wong, 2004; Rakha et al., 2007). Many works are only focused on the technique of measurement. In study (Guzek et al., 2012), the authors show how to make measurements and collect data using methods of video analysis from cameras installed at the inlet of intersections. There are also a publications, in which the authors take the attempt to create the specific drivers reactions model, taking into account the moment of start braking or the moment when driver decided to start the movement through the stop line (Elmitiny et al. 2010). In (Tang and Nakamura, 2007; Tang and Nakamura, 2008) the impact analysis of traffic signals length on the driver's behavior and time lost at the junction was made. Another interesting aspect shown in (Li et all., 2014) is study of the importance of information about the remaining time before the end of the red signal on the drivers reaction time. The authors demonstrated that the above information for drivers leads to a decrease in reaction time when the green light is transmitted. In addition, the paper presents a highly efficient method for the determination of the mentioned reaction time, based on digital image processing. Regarding to the works of domestic authors the results of complex studies conducted at the crossroads of the city of Krakow were presented in (Chodur and Ostrowski, 2012; Ostrowski, 2011). The research results show that the determinants in the location of the intersection (the urban or suburban road), type of lane (internal, external), etc. play an important role in the calculation of the value of the driver's reaction time parameter.
Summing up the conclusions from the analyzed positions of the literary sources it can be stated that the problem of the drivers reaction for phase change at the intersection with the traffic lights went through many comprehensive studies taking into account numerous aspects and factors. However, a little information and research was found on the impact of driver's reaction time parameter on the emissions level from moving vehicles through the intersection. In relation to the above, it is necessary to conduct a more in-depth analysis and research in this area.

3. Microscopic traffic simulation

Currently noticeable trend in the field of traffic engineering is the application of computer tools to microscopic simulations. Microscopic traffic simulations are used to determine the characteristics of the processes occurring in streams of traffic, and to perform their analysis. Traffic flow and cars motion in simulations are often based on models describing the drivers behavior, for example, the Car following model or the Lane changing model. The traffic simulator Aimsun 8.1 is a computer software whose functionality is allowing to simulate traffic on three levels of detail modeling: micro-, meso - and macroscopic.
In terms of the microscopic, behavior of each vehicles (e.g., selected movement speed) is determined on the basis of the conditions around the vehicle e.g. the way of moving by preceding vehicle, or a vehicle next to it, the status of traffic lights, information provided by traffic signs, as well as congestion occurring on the road. The microscopic simulation in Aimsun software assumes, the movement of the vehicle is calculated according to Car following model or the Lane changing model, developed by P. G. Gipps (Aimsun, 2014). The first model, suggests that the vehicle speed in the *i*-th step of simulation is determined by: readiness of the acceleration to a certain speed parameter, downturn following from local conditions of the vehicle (speed limit, weather conditions) and driver reaction time (Aimsun, 2014). Given the fact that the consideration of this work concern the behavior of drivers, the authors focus their attention on the last element of the model.

4. Drivers reaction time

The one of the basic information in microscopic traffic simulation which has a significant impact on the progress and result of simulation, are the parameters describing the drivers behavior. In the current version of Aimsun, there are three main types of parameters related with driver time response (Aimsun, 2014):

1. Reaction time in traffic - is the response time, what is needed for the driver to adjust their speed to the preceding vehicle,
2. Reaction time at a standstill - the reaction time at the start of the preceding vehicle, which a driver need to start acceleration from a standstill,
3. Reaction time to traffic lights - is the reaction time to green light appearance at the intersection, when a driver is about to start moving.

The first parameter is used in the mentioned Following vehicles Gipps model. This means how fast the driver adjusts their speed to the speed of running ahead of his vehicle. As indicated in (Mehmood and Easa, 2009) reaction time on the resultant motion of two parameters: Acceleration or braking reaction time, marked as RP/Z; the Break-reaction time, marked as RH. Time RP/S is the difference between the receipt of the light signal for the driver to match their speed, and the start of the correction to his speed. Similarly, we can determine the time of RH as the difference between the receipt of the signal stop light the vehicle in front, and at the time of driver response to the signal. In (Jurecki et al., 2012) this time indicated as the psychomotor reaction time during braking, as the time from the onset of the obstacles before the efforts on the brake pedal is defined. In addition, the reaction, the braking reaction time can take on different meanings depending on the situation, for example, if the driver responds to stationary traffic (congestion conditions), normal, or emergency situations.

As follows from the performed reviews, it has no direct studies to determine the values of the reaction time of acceleration/deceleration. For studies that indirectly analyze these phenomena, the one presented in (Chodur and Ostrowski, 2012), all measurements intervals between successive vehicles pass a line stop on the city roads and countryside during the phase of green light were performed. The magnitude of measured time interval may be not enough to describe the time RP/Z. From these studies implies that, depending on weather conditions from the first vehicles to impose certain behavior of other drivers of vehicles queue (Ostrowski, 2011). The average time interval between vehicles on urban roads amounted to 1.87 [sec.], and the standard deviation was 0.18 [sec.]. An interesting phenomenon that was observed in the above studies, it is a gradual reduction of the distance between vehicles in the final phase of the green signal. Additionally was investigated that in Krakow in saturation traffic (e.g., peak traffic) from 8% to 25% of drivers passing on yellow and red signal, which is illegal. Both behaviors significantly affect the security level and the capacity of the intersections.

The second element is the reaction time of the driver in traffic reaction time to braking. If this option was made quite a comprehensive study, presented in (Jurecki and Stańczyk, 2011). Analyses are performed in the driving simulator on a machine in the cockpit of the vehicle using the specialized software, as well as in studies of the landfill that is used for subsequent verification of the simulation. For the sample of 107 participants, aged from 25 years to over 46 years, it was obtained the mean reaction time for braking is in the range of 0.42-0.92 per seconds, and the standard deviation is 0.05 to 0.29 seconds.

5. Selected traffic parameters

Avg Approach Delay: it is calculated as the sum of delay time of each link weighted by the link flow and then divided by the total flow.
Flow: average number of vehicles per hour that have passed through the network during the simulation period. The vehicles are counted when leaving the network via an exit section
Travel Time: average time a vehicle needs to travel one kilometer inside the network. This is the mean of all the single travel times (exit time - entrance time) for every vehicle that has crossed the network, converted into time per kilometre.
Delay Time: average delay time per vehicle per kilometer. This is the difference between the expected travel time (the time it would take to traverse the system under ideal conditions) and the travel time. It is calculated as the average of all vehicles and then converted into time per kilometer.
Stop Time: average time at standstill per vehicle per kilometer.
Number of Stops: average number of stops per vehicle per kilometer.
Mean Queue: average length of the queue in that section, expressed as the number of vehicles per lane. It is calculated as a time average.
Vehicles Waiting to Enter - Number of vehicles waiting to enter the network

Additionally the Aimsun software can model instantaneous pollution emissions caused by acceleration/deceleration and speed for all the vehicles in the simulation based on the paper by Luc Int Panis, Steven Broekx, Ronghui Lui: Modelling instantaneous traffic emission and the influence of traffic speed limits. Each simulation step it measures the emissions for each pollutant using the same formula, but considering different factor values according to the vehicle type, the fuel type and instant acceleration/deceleration measures. In particular, the instantaneous emission model considers Carbon Dioxide (CO_2), Nitrogen Oxides (NO_x), Volatile Organic Compounds (VOC) and Particulate Matter (PM).

6. Simulation results - Case study of Cracow

In the conducted research, the traffic microsimulation of one of the Cracow main arteries (so-called Trzech Wieszczy Avenue) was made. The simulation included the time of morning peak hours and was made based on real traffic volume measurements. In order obtain results indicating how significantly the behavior of drivers affect the emission level, four simulation scenarios have been defined:

– Variant 0 – assumes that actual values of the reaction time (based on the literature review) has been taken to the simulation

– Variant 1 - assumes that drivers follow the traffic laws. It means that drivers do not enter the centre of the intersection when the yellow signal is transmitted at the end of the green phase (late move),

– Variant 2 - assumes that drivers follow the traffic laws, drivers do not enter the centre of the intersection when the yellow signal is transmitted at the beginning of the green phase (early start),

– Variant 1 and 2 assumes that drivers pass through the intersection only when the signal is green.

Based on the above assumptions it was checked what would happen if the driver in Krakow was driving in accordance with the law, and how the behavior of the early start and late passage through the intersection affect the flow parameters and exhaust emissions. The results of this analysis are presented in tables below: for road sections (Table 1), intersections (Table 2) and the whole road network (Table 3).

Table 1

The values of traffic parameters and vehicle emissions, depending on the behavior variants for selected road sections of the road network of Krakow

	Traffic parameter				Pollutant emission		
	Total flow [veh./h]	Mean Queue [veh.]	Number of stops [-/veh./km]	Mean delay time [sec./km]	CO2 [g]	NOx [g]	PM [g]
Variant 0	79 967.00	2.88	57.54	44.06	5 153 006.80	8 212.31	1 258.25
Variant 1	80 800.00	2.93	58.83	53.01	5 197 723,59	8 165,38	1 252.92
Variant 2	76 523.00	3.07	60.51	50.76	5 084 070.03	8 218,08	1 214.11
Variant 1 and 2	79 560.00	3.04	61.22	53.04	5 172 211.14	8 160.08	1 224.85
	Percentage increase/decrease in reference to Variant 0						
Variant 1	-1.04%	-2.03%	-2.24%	-20.30%	-0.87%	0.57%	0.42%
Variant 2	4.31%	-6.91%	-5.17%	-15.20%	1.34%	-0.07%	3.51%
Variant 1 and 2	0.51%	-5.78%	-6.40%	-20.36%	-0.37%	0.64%	2.65%

Table 3
The values of traffic parameters and vehicle emissions, depending on the behavior variants for the selected road network of Krakow

		Percentage increase/decrease in reference to Variant 0		
		Variant 1	**Variant 2**	**Variant 2 and 3**
Traffic parameters	Mean delay time	-3.95%	-4.11%	-8.63%
	Mean flow	-0.02%	4.06%	1.23%
	Mean queue	1.65%	-6.83%	-2.42%
	Mean number of stops	0.00%	0.00%	0.00%
	Mean stop time	-4.71%	-5.07%	-10.43%
	Mean travel time	-3.20%	-3.36%	-6.93%
	Vehicle waiting to enter	-1.49%	-58.51%	-62.99%
Pollutant emission	CO2	-0.58%	1.64%	0.17%
	NOx	0.54%	0.28%	0.96%
	PM	0.85%	3.47%	3.20%

Source: own elaboration

The increase of reaction time on the traffic lights (Variant 2), as well as reducing unauthorized entries into the intersection (Variant 1) resulted in a deterioration of traffic conditions in the analyzed network. This is especially noticeable in average delays at road links and junctions, respectively, the growth even by 20.36% and 12,51%. Despite the fact of realization both the proper behavior of drivers (Variant 1 and 2) the number of vehicles in the analyzed roads is not different from Variant 0, but the capacity of an entire road network decreases (Table 3). This is due to the direct influence of the analyzed reaction time on intersections capacity, which is in this case the main determinant of the capacity of the whole network (Trzech Wieszczy Avenue is one of the most congested roads in Krakow during morning peak hours).
Despite worsening traffic conditions, the values of the estimated emissions have decreased. The best benefits can be achieved for the PM pollution. This is highly relevant information for the analyzed case because the one of the main causes of smog in Krakow is that kind of substance. In the case of implementing both Variants (1 and 2) emission at intersections decreased by almost 5% (Table 2). Additionally it is also very important that, there is no correlation between the increase/decrease traffic parameters and the amount of emissions. For example, increase average delay more than 8% caused a reduction in emissions of NOx and PM more than 3%. This means that reduction of emissions level are not obtained only through a reduced number of vehicles in the network.
In addition, comparing both types of driver behaviour it can be noted that the elimination of the late entry the intersections does not make worse traffic conditions, as the elimination of the early start of the vehicle at intersections . This means that the capacity of intersections is increased mainly by the early start drivers at traffic lights. However, the improvement of traffic parameters causes the expense of emissions - early start generates more emissions of the all considered gases. This is probably associated with a significant increase vehicles fuel consumption, when they performing sudden and sharp acceleration.

7. Conclusions

The drivers behaviors significantly influence and shape the traffic conditions in the cities. Characteristic behavior for the given region (city) can positively or negatively affect the environment. In this example, the illegal behavior of drivers within the intersections have a positive effect on the capacity of intersections. As a consequence of this situation is unfortunately, the increase of exhaust emissions as well as decrease of safety level. Therefore the local authorities should determine priorities of the traffic control to optimize the social and environmental nuisance of road traffic.
Further studies on the influence of driver behavior on the road traffic parameters and value of the emissions will be focused on considering drivers behavior in traffic as well as taking into account other road users other than passenger cars.

THEORETICAL ANALYSIS OF THE EFFECT OF DIFFERENT SPEED DISTRIBUTIONS ON VEHICLES EMISSION ESTIMATION

Mohammad Maghrour Zefreh[1], Adam Torok[2]
[1,2] BME – Budapest University of Technology and Economics, Department of Transport Technology and Economics, Budapest, Hungary

Abstract: Vehicles speed distribution is an important input parameter in lots of issues, such as kinematical traffic simulation model, road design, speed limit evaluation, road traffic noise prediction as well as vehicles emission estimation. In this paper, a new approach has been presented in which the speed is randomly generated according to different unimodal speed distributions, and then these speed distributions have been disaggregated using Monte Carlo Method to assign the speed to each and every vehicle. These different distributions are chosen according to the contextual traffic situation (free flow, pulsed accelerated flow, intersection, congestion, etc.). The effect of these different speed distributions on vehicles emission has been surveyed using speed related emission models in a theoretical path. The study of the influence of different distributions on the resulting emission level has been performed. This result leads to the chance in revising the simulation software in further studies by extending these results in bimodal speed distributions and their related emission models. The considerable difference in the emission models related to Log-normal distribution as well as exponential, chi-square and equal distribution to normal Gaussian distribution implies that these different traffic conditions will have a considerable effect on emission even in the unimodal traffic conditions.

Keywords: speed distribution, Monte Carlo method, speed related emission models.

1. Introduction

Data on speeds and travel times of motor vehicles are essential to traffic engineers responsible for design and operation (Berry et al. 1951). Speed is the fundamental measure of traffic performance of a road transport. It indicates the quality of service experienced by the users. Many researchers have put effort for modelling speed either for the homogeneous or mixed traffic conditions (McLean 1978), (Katti et al. 1988), (Shankar and Mannering 1998), (Dixon et al. 1999), (McFadden et al. 2001), (Figueroa and Tarko 2004), (Ali et al. 2007), (Himes and Donnell 2010), (Munawar 2011), (Dhamaniya and Satish 2013), (Tettamanti et al. 2015), (Rao and Rao, 2015). The development of mathematical tools focused on the modelling of the speed distribution in a traffic flow is widely reported in the scientific literature (Castro et al. 2008), (Dey et al. 2006), (Fitzpatrick et al. 2000), (Trozzi et al. 1996). Many papers concern this problem since vehicles speed distribution is an important input parameter in lots of issues, such as kinematical traffic simulation model, road design, speed limit evaluation, road traffic noise prediction, traffic safety evaluation, bicycle performance evaluation, analysis of pedestrian walking (Iannone et al. 2013), (Berry et al. 1951), (Lin et al. 2008), (Wang et al. 2015), (Vadeby and Forsman 2014), (Maurya et al. 2015), (Hustim and Fujimoto 2012), (Aly et al. 2012), (Chandra and Bharti 2013) etc. Since 1940 majority of papers considered speed distribution as Gaussian or Normal distribution (Loutzenheiser and Greenshields 1940) and only extreme situations are considered as the traffic volume exceeds the practical road capacity, the speed distribution may become so heavily skewed toward the higher speeds that all semblance of normality is lost. Modern traffic simulation softwares are also using Gaussian normal distribution for traffic speed estimation and also have built-in emission estimation models (Batterman et. al. 2010). Therefore, the connection between the distribution of speeds and emission is of great importance in this case. Around the world road traffic is the dominant anthropogenic source of air pollution in urban areas (Fenger 1999). Several cities in Europe are facing traffic congestion problem daily in a critical level. Traffic congestion is known to exacerbate emissions from mobile sources in urban areas, thus contributing to air quality deterioration with significant health, environmental and economic impacts (Smit et al. 2008). Emission tests on modern cars with advanced emission control systems (DoTRS 2001) have demonstrated that their emissions are particularly sensitive to the occurrence of congestion in the driving cycle. In this situation, the motor vehicles such as passenger cars and motorcycles have made zigzag maneuvers disturbing the travel speed (Maghrour Zefreh et al. 2015) and behaviours that are insufficient for the mentioned traffic condition. Therefore, the motor vehicles behaviour may change from homogeneous situations to heterogeneous conditions. The remainder of this paper is organized as follows: Section 2 describes how the methodology processed in order to disaggregate different velocity distributions and then estimates their related emission. Section 3 presents the results and the outputs of different velocity distributions and emission distributions. Section 4 compares speed related emission distributions with normal Gaussian distribution. Finally, Section 5 summarizes the conclusions.

2. Methodology

As suggested in literature, speed distribution models might be useful in the development of traffic simulation model for vehicle emission and traffic noise predictions (Hustim and Isran 2013). For comparing the effect of different speed distributions on emission estimation, a theoretical path has been investigated in this research. The average speed, number of vehicles and the speed distribution are given as an assumption. It should be underlined that the number of vehicles, their average speed, and travel distance are remain constant in all cases. The emission is estimated based on

[1] Corresponding author: mohammad.maghrour@mail.bme.hu

different speed distributions using the so-called speed based emission models. Speed based emission models, like MOBILE (USEPA 2007), EMFAC (CARB 2002), COPERT (EEA 2000) and others (e.g. Namdeo et al. 2002), are regularly applied in practice. In these models, emission factors (g km1) are stated as a function of average speed. Traffic situation models use discrete emission factors (g km1) for certain traffic situations, which can be defined in terms of a textual description (e.g. INFRAS 2007) or by a set of quantitative variables (e.g. TNO 2001). In the present research, first the random speeds were generated by determining the discrete probability variable based on different distributions according to different traffic conditions (discussed later). Then the speed distributions were disaggregated using Monte Carlo method after programming the macro environment of the MS excel software. With this method, based on the distribution individual speed could be assigned to each vehicle. This process has been shown in Fig. 1.

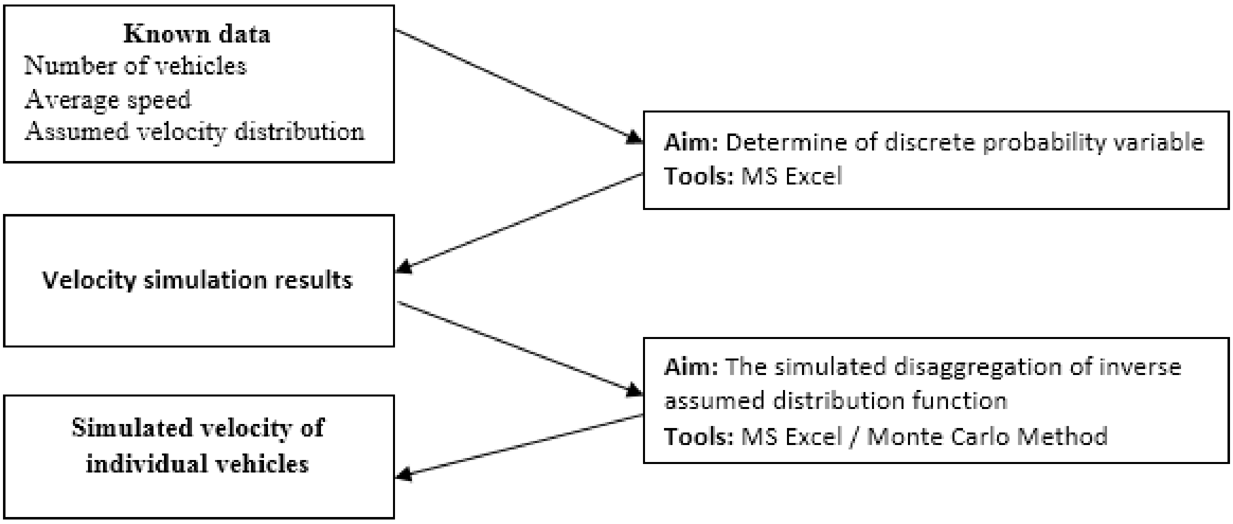

Fig. 1.
Simulation Process

Monte-Carlo methods (or Monte-Carlo simulations) are computational algorithms that rely on repeated random sampling (Torok 2015). Typically simulations run many times in order to obtain the distribution of an unknown probabilistic parameter. Monte Carlo methods are mainly used in three distinct problem classes: optimization, numerical integration, and generating draws from a probability distribution (Kroese et al. 2014). It provides a powerful computational framework for spatial analysis and has been used to disaggregate data in areal units to individual points (Hu and Wang 2015). For example, Watanatada and Ben-Akiva (1979) used it to simulate representative individuals distributed in an urban area for travel demand analysis. Wegener (1985) designed a Monte Carlo based housing market model to analyse location decisions of industry and households and corresponding migration and travel patterns. Gao et al. (2013) applied it to simulate resident and business distributions proportionally to mobile phone Erlang values and to predict traffic flow in a road network. Basically, the Monte Carlo method generates suitable random numbers of parameters or inputs to explore the behaviour of a complex system or process. The random numbers generated follow a certain probability distribution function (PDF) that describes the occurrence probability of an event. The detailed velocity disaggregation flow chart using Monte Carlo method is shown in Fig. 2.

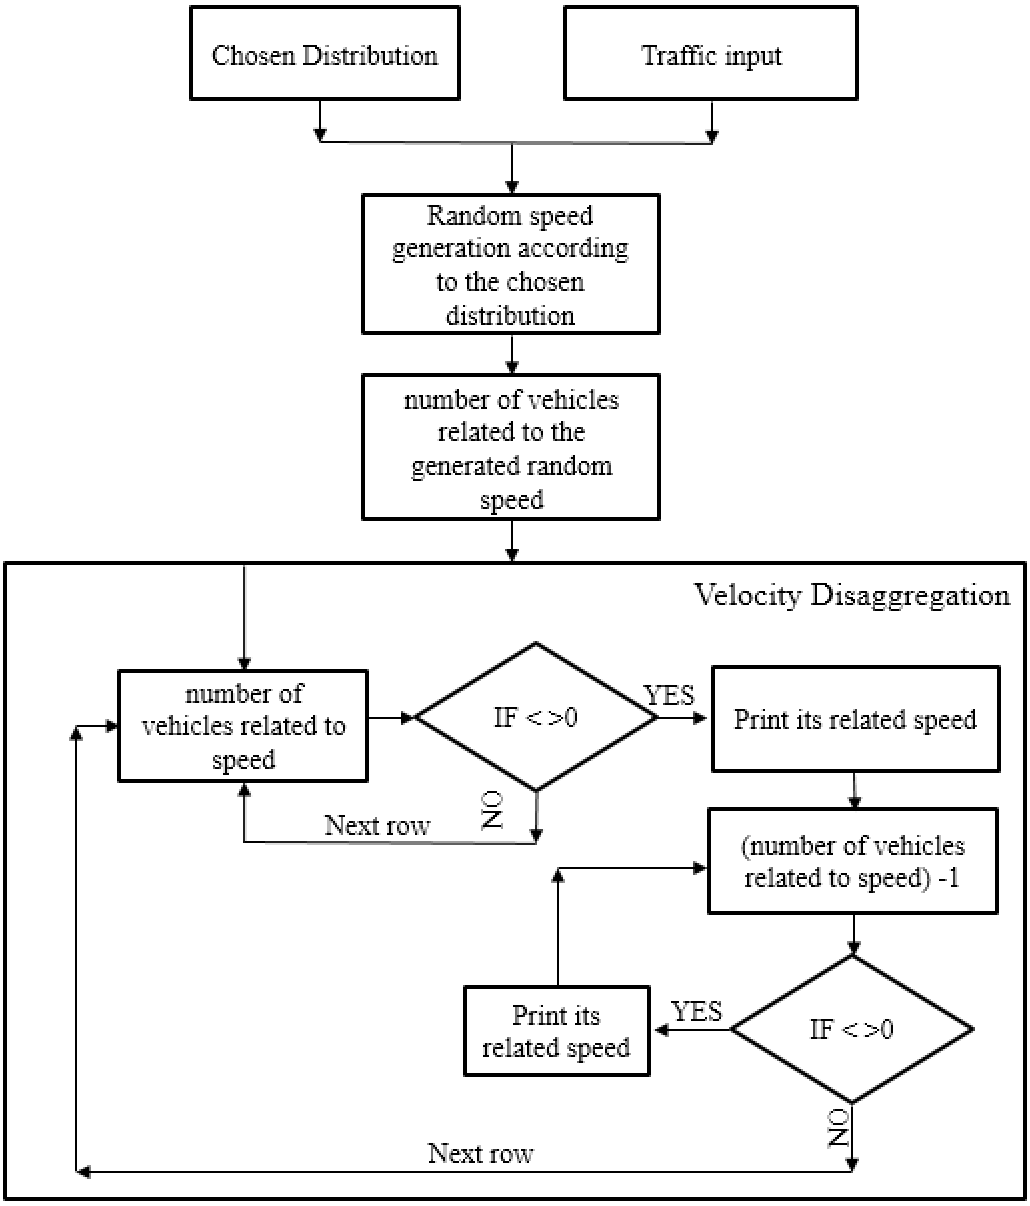

Fig. 2.
Detailed Flow Chart of Velocity Disaggregation

In this paper, the authors focus on the different probability distributions that can be chosen for vehicles speed, depending on the traffic flow conditions. The main aim of this paper is to survey on speed related emission models based on different speed distribution in a theoretical path. These different speed distributions based on different traffic conditions are shown in Fig. 3. If the traffic conditions are not homogeneous, the normal distribution is not well suitable anymore. There is a lot of research that has examined distribution models for motorized vehicle speed data, such as normal distribution, skewed distribution, and composite distribution. In regard to normal distribution, Leong (1968) and McLean (1978) found that, for lightly trafficked two-lane roads where most vehicles are traveling freely, car speeds measured in time are approximately normally distributed with a coefficient of variation ranging from about 0.11–0.18. Minh et al. (2005) have studied that the speed distribution followed the normal distribution on the urban road. Wang et al. (2012) introduced truncated normal and lognormal distribution for modeling speeds and travel time. Yajie Zou (2013) proposed that skew-t distribution can reasonably take into account the heterogeneity in vehicle speed data. Zou and Zhang (2011) said that a single normal distribution cannot accurately accommodate the excess kurtosis present in the speed distribution and they proposed skew-normal and skew-t distribution to fit speed data. They suggested that these two distributions can be applied effectively for both homogeneous and heterogeneous traffic. Haight and Mosher (1962), considered that the speed data could be well represented by either a gamma or a log-normal distribution. Gerlough and Huber (1975) proposed the use of the log-normal distribution. This resembles the normal distribution but is skewed with a larger tail to the right. These distributions offer the advantage that the same functional form is retained when the time speed distribution is transformed into a space-speed distribution and avoid the theoretical difficulty of the negative speeds given by the infinite tails of the normal distribution. Iannone et al. (2013) assumed that a reasonable choice for the pulsed accelerated flow is the Beta distribution while the Chi-Square is proposed for the decelerated flow simulation. This assumption is supported by Harmonoise (2004), where different speed distributions are related to different traffic situations. The conditions that turn to a different speed distribution are quite often realized in non-highway or urban roads, where, in general, the traffic stream is much more complicated. This assumption is supported by (Török and Maghrour Zefreh 2016), where there is a need for applying multimodal speed distribution in road transport emission estimation when the traffic stream is complicated. This large spread of typologies, together with other parameters such as the presence of traffic lights and the road surface conditions, leads to a significant deviation of the speed distribution curve from the generally accepted single modal normal distribution (Iannone et al. 2013). Jun (2010) investigated traffic congestion trends by speed patterns during holiday travel periods using the normal mixture model. He suggested, during heavy congestion speed data shows bimodality which cannot be represented by a single distribution, two different Gaussian mixture model will be required, one mixture component representing low-speed regime and another for high speed. Overall some roadway sections may have more than two modes, e.g., uncongested speed range, interim speed range which lies between uncongested and congested conditions, and congested speed range. The change between unimodal speed distribution and bimodal speed distribution will indicate the pattern of traffic variations of specific interstate freeway systems (Ko and Guensler 2005). In this paper different unimodal speed distributions according to different traffic conditions (congested condition or uncongested condition) have been assumed as a dominant condition and mixed traffic conditions have not been investigated due to the limitation of bimodality distribution in our statistical software MS Excel.

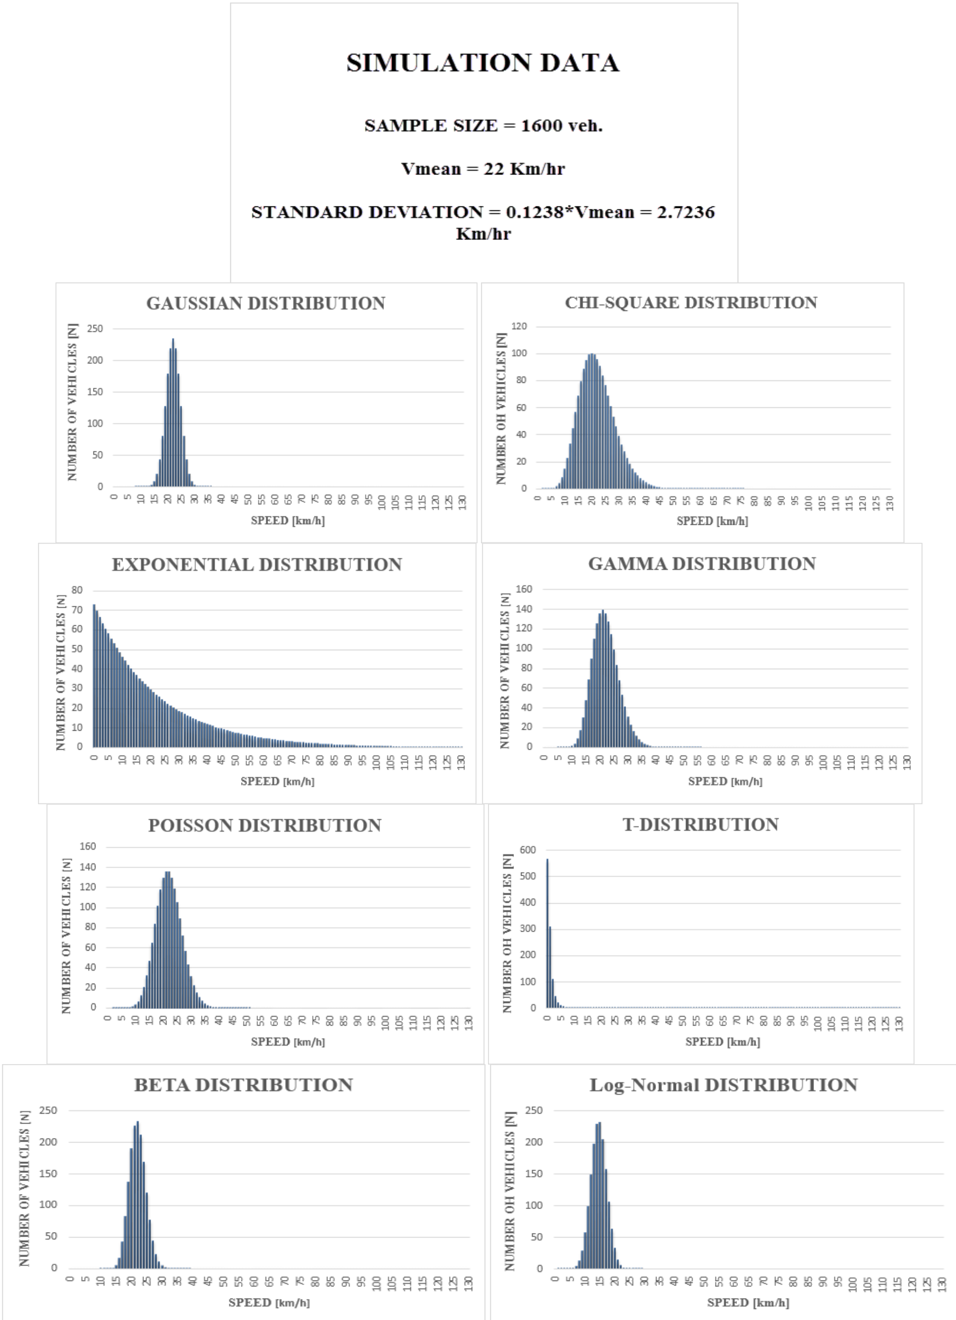

Fig. 3.
Random Speed Generation According to Different Distributions Based on Different Traffic Conditions

After generating random speeds based on the chosen distribution, these speeds were disaggregated using Monte Carlo Method to assign the speeds to each and every vehicle. These disaggregated speeds were used to build emission models related to these speed distributions. The environmental impact of road transport is a relevant issue in the framework of urban settlements since the traffic affect human being health, especially concerning air pollution. Road transport related emission estimating models started to be developed more than 50 years ago and they often show satisfactory results. The main inputs of these kinds of models were traffic flow for each category of vehicles, specific fuel consumption and vehicle speed. Moreover, many models have been developed around the world considering more and more parameters related to road transport specialities of different countries. All these models started from a statistical approach to the emission estimation that generally does not take into account any terms regarding speed distribution only constant fuel consumption. More recent models, starting from a more precise classification into several categories (basically in Europe the EURO environmental emission categories are considered), improve the accuracy of predictions. Nowadays one of the most important development that should be considered is the dependence from the speed. Of course, one could think to overcome this problem by performing a measurement campaign (huge investment and huge effort), but the development of a new model, based on a microscopic approach with laboratory tests, able to describe every kind of traffic condition, results to be an interesting challenge. For this purpose, the Euro II gasoline passenger car with the engine capacity of 1.4-2.0 litre have been chosen for better comparability. Based on the European Environmental Agency Emission Inventory Guidebook (Ntziachristos, Samaras, 2012) the fuel consumption based CO2 emission can be polynomial estimated as a generic function between 10 and 130 km/h (1):

$$\varepsilon_{CO_2}[g_{CO_2}] = \frac{(3.47 \cdot 10^2 + 2.73 \cdot v + 4.28 \cdot 10^{-3} \cdot v^2)}{(1 + 2.71 \cdot 10^{-1} \cdot v - 9.11 \cdot 10^{-4} \cdot v^2)} [g_{fuel}/km] \cdot 3.088 \left[\frac{gCO_2}{g_{fuel}}\right] \cdot 1[km] \qquad (1)$$

3. Results

After generating the random speeds based on different speed distributions, the generated speeds have been disaggregated using Monte Carlo Method. Their distributions have been shown in Fig. 4.

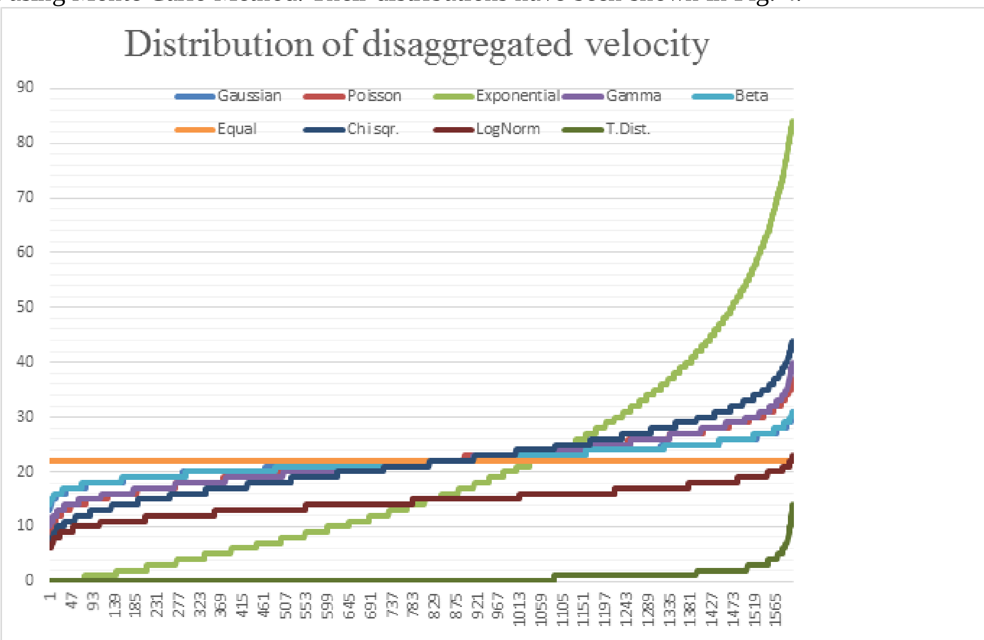

Fig. 4.
Nine Different Distribution of Disaggregated Velocity With Same Input Data

By taking all of these distributions into account in the mentioned interval (10 to 130 km/h), the samples would drastically decrease from 1600 vehicles to just 6 vehicles. Therefore, it was decided to get rid of T-distribution samples to cover more samples (about 1000 vehicles out of 1600 vehicles) as the inputs of emission models. Based on these speed distributions their related emission distributions were calculated. The results have been shown in Fig. 5.

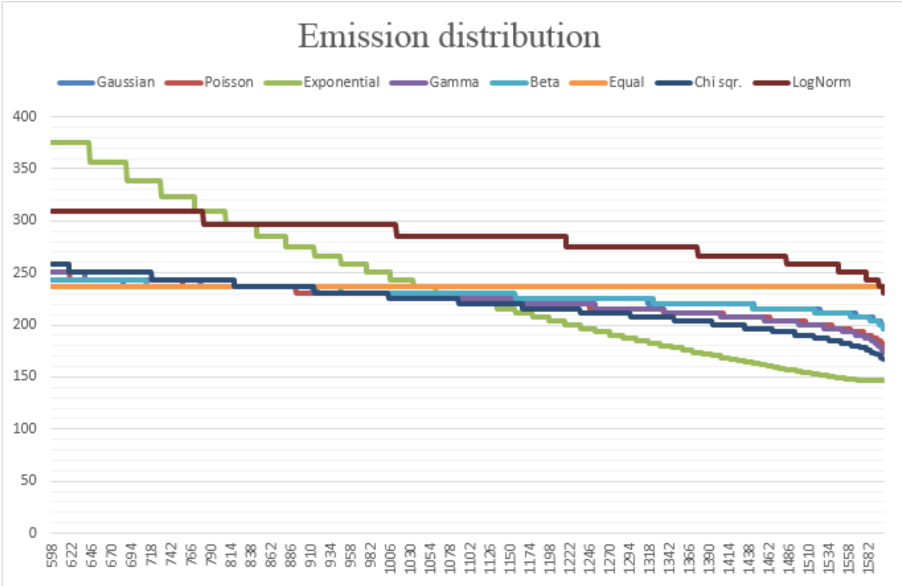

Fig. 5.
Eight Different Emission Distribution Based on Their Speed Distribution

4. Analysis and Discussion

The comparison of these emission distributions is shown in Fig. 6.

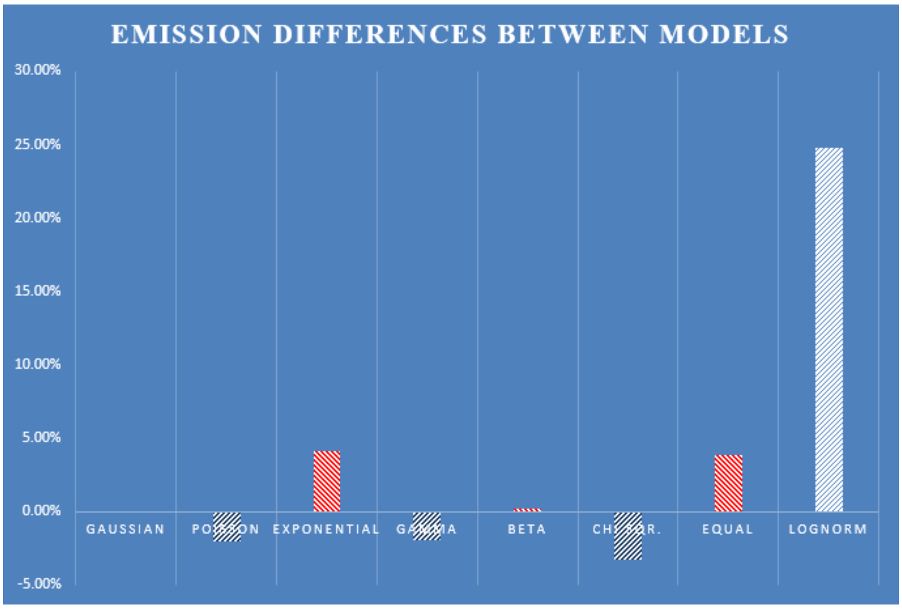

Fig. 6.
Comparing all emission models with Gaussian distribution

By taking a wide look at Fig. 6, it could be expected that the more precise distribution modelling would be useful and would cause significant differences in microsimulation and emission modelling.

5. Conclusion

In this paper, the authors introduced the speed distribution of the vehicular traffic flow in the evaluation of emission modelling. Any emission modelling made by unimodal traffic condition whereas the standard conditions are not negligible. By introducing the dependence of speed curve profiles, the authors developed a more realistic prediction tool, able to consider the intrinsic stochastic feature of traffic phenomenon. The study of the influence of different distributions on the resulting emission level has been performed. This result leads to the chance in revising the simulation software in further studies by extending these results in bimodal speed distributions and their related emission models. The considerable difference in the emission models related to Log-normal distribution as well as exponential, chi-square and equal distribution to normal Gaussian distribution implies that these different traffic conditions will have a considerable effect on emission even in the unimodal traffic conditions.

POTENTIAL OF TROPOSPHERIC OZONE FORMATION FROM SOLVENTBORNE ROAD MARKING PAINTS IN ADRIATIC SEA BASIN

[1] *M. Swarovski GmbH; Industriestrasse 10, 3300 Amstetten, Austria*
[2,3] *Kraków University of Technology, Civil Engineering Department, Transport Section; ul. Warszawska 24, 31-155 Kraków, Poland*

Abstract: Ground-level ozone is a significant pulmonary irritant, responsible for numerous of premature deaths worldwide. Ozone forms during solar irradiation-mediated decomposition of nitrogen dioxide to nitrogen oxide, which leads to its high levels in areas of high insolation. Volatile Organic Compounds (VOC) undergo decomposition *via* photolysis and interact with nitrogen oxide, pushing the reaction equilibrium to increased ozone formation. Different solvents decompose in the atmosphere by different chemical pathways and thus have dissimilar effect on the ozone formation; the effects were quantified in their Maximum Incremental Reactivities (MIR). Solventborne road marking paints contain about 24% of VOCs, which affect ozone formation; therefore, it is critical that the solvents are selected to minimise the negative effects. In this contribution, MIR were used to calculate tropospheric ozone formation potential from several road marking paints used in Adriatic Sea basin, where there are specific issues associated with very high insolation and where weather conditions favour high ozone concentration episodes. It was calculated that well-designed waterborne road marking paints can have 27-fold lower ozone formation potential than toluene-based paints, in addition to furnishing 85% lesser VOC emissions.

Keywords: tropospheric ozone, maximum incremental reactivity, volatile organic compounds, waterborne road marking, solventborne paints, horizontal road markings, glass beads.

1. Background

Tropospheric ozone is formed from nitrogen dioxide, which under photolytic conditions is decomposing to nitrogen oxide and oxygen radical, per mechanism proposed by Chameides and Walker (1973). The levels of nitrogen oxide, nitrogen dioxide, and ozone form equilibrium. VOCs, which decompose *via* hydroxy radicals, affect the equilibrium by reacting with nitrogen oxide, which was first observed by Leighton (1961) and elucidated by Crutzen (1974). Generally, the decomposition products of VOCs increase formation of ozone. Carter (1994) has quantified the effect of particular VOCs on ozone formation and developed MIR.

Horizontal road markings are amongst the most commonly used and most effective safety features on all of the modern roads. Current technologies do not permit for their replacement with any other means. The markings are systems consisting of pigmented layer and reflective elements. Various types of road markings were recently reviewed by Babić and colleagues (2015).

Emissions of solvents from solventborne road marking paints affect formation of ground-level ozone, as we have reported in two preceding papers concentrating on emissions in Poland (Burghardt et al., 2016, 2016a). Herein, we discuss several specific issues associated with high-insolation areas and regions prone to high ozone concentrations and analyse several road marking paints used in this region in terms of their potential of ground-level ozone formation.

1.1. Tropospheric ozone

Ozone, a tri-molecular allotrope of oxygen, forms in the atmosphere during lightning and is present mostly in the stratosphere, where it is required as a scavenger of ultraviolet radiation. In troposphere, ozone is rather undesired, because it is a reactive species that causes irritation to respiratory system, it is a significant component of summertime non-particulate smog. Simultaneously, one must remember that it is a critical part of troposphere's self-cleaning processes. A plethora of reports link increased ground-level ozone concentration with increased mortality and morbidity: Amman (2009) estimated that loss of 22 thousand of lives in 25 countries subjected to the evaluation in 2008 could be linked to tropospheric ozone. An OECD report (2012) indicated annual worldwide premature deaths caused by ground-level ozone pollution, after statistical separation from the effects of other air contaminants, to be between 50 000 and 350 000.

In addition to being harmful to humans, tropospheric ozone causes damage to plants, in some cases quite severe (Fumagalli et al., 2001).

Annually-averaged background ozone concentration in areas devoid of industrial or man-made sources was reported by Vingarzan (2004) to have risen by up to 50% over the past 100 years in for mid-latitudes of Northern Hemisphere regions.

1.2. Tropospheric ozone in Mediterranean basin

Mediterranean basin is quite a specific area due to high insolation, high emissions of ozone precursors, and weather conditions. During summer, stable high air pressure and anti-cyclonic air circulation favour ozone formation and

[3] Corresponding author: lzakowsk@pk.edu.pl

disfavour its natural titration by nitrogen oxide. Ozone reservoirs are formed off-shore because at night the land breezes move the ozone-polluted air to stay above the sea; the air masses then return to the shore during daytime to add to ozone pollution. The prevailing calm winds do not afford sufficient dispersion of the pollutants. Such air masses movements were reported by Prtenjak et al. (2013) as responsible for a high-ozone episode that occurred in Rijeka, Croatia in 2000 when night-time ozone level was exceeding 100 μg/m³ and during the day was around 180 μg/m³. Due to the same transport mechanism, high ozone concentrations can also occur at remote sites (Monteiro et al., 2012).
Quite interestingly, analysis of ozone concentration levels from 214 measuring stations in Mediterranean region over the first decade of 21st century demonstrated that at rural stations ozone concentrations were decreasing by an average of 0.43% annually. Simultaneously, at suburban and urban stations the average levels were increasing respectively by 0.46% and 0.64% per year. The increases in urban area were attributed, paradoxically, to stricter vehicular emissions controls that lowered the availability of nitrogen oxides (Sicard et al., 2014).

1.3. Horizontal road markings systems

Horizontal road markings are ubiquitous road safety feature. Their influence on environment can be profound and numerous legislations throughout the world have been imposed to limit the use of various substances that may be harmful to human health or safety and the environment. Modern road marking materials are devoid of heavy metals and chlorinated solvents. In some countries, also aromatic solvents are prohibited or limited and restrictions on VOC emissions are imposed. Solvent- or water-borne paints, coldplastic, and thermoplastic masses are the most commonly used pigmented layers.
The best analysis to seek minimum environmental impact appears be the use of cradle-to-grave Life Cycle Assessment (LCA). Such analysis recently performed on water- and solvent-borne road marking paints demonstrated that the key parameter was **system durability**. However, even though the LCA included the environmental impact of the emitted VOCs, we have questioned whether the location of emissions and ozone formation potential should not be considered as an important additional factor in the light of the impact of tropospheric ozone and other pollutants on human health (Burghardt et al., 2016a).
The influence of horizontal road marking paints on VOC emissions has been recognised by various environmental authorities and norms were established. However, it only seems reasonable to assume that improvement in air quality in areas of high ozone concentrations can be accomplished by minimising the emissions of VOCs that have highest MIR. A recent analysis from South California Air Quality Management District (SCAQMD), for which the MIR scales were developed, has shown that traffic paints along with related coatings contributed 1.1 tonnes of VOCs per day in the SCAQMD area comprising 27 850 km² and inhabited by almost 18 million people. Reactivity-weighted emissions, based on MIR analyses, were calculated to be similar (Chen and Luo, 2012).
A key component in road marking systems are drop-on glass beads that provide retroreflectivity at night and simultaneously protect the pigmented layer. The selection and quality of glass beads is one of the critical parameters, possibly the most important, for systems durability. At this Conference and at European Road Infrastructure Congress is being demonstrated that the use of highest quality glass beads leads not only to exquisite retroreflectivity, but also to exceptional systems durability (Mosböck and Burghardt, 2016; Burghardt, Babić, and Babić, 2016). Thus, glass beads for road marking may indirectly also affect the amounts of emissions of solvents and potential of ground-level ozone formation.

2. Methodology

In our analysis, we are utilising MIR rather than VOC emissions to assess the effects of solvents from road marking paints on environment. The use of MIRs, which are expressed in the unit of grams of potentially formed ozone per gram of VOC, makes calculations very simple and straightforward. From chemistry point of view, the unit is quite strange, because all chemical reactions are taking place on molar basis, but the scales were developed for SCAQMD, which deals with tonnes of emissions. MIR values published in California Code of Regulations, Title 17, Chapter 8, §94700 are used.
Similarly to our (2016) analysis done on road marking paints in Poland, we have used freely available Safety Data Sheets (SDS) of a few solventborne road marking paints as the source of solvent composition. For simplicity, in all of the cases we have assumed the volatile materials content at 24%; where concentrations ranges were given, we have taken the proportional amounts to obtain 24% of volatiles. We were not able to obtain the amounts of actually utilised solventborne paints, because such information is proprietary to the road marking companies. It is due to the existence of full maintenance contracts (including, in addition to maintaining the horizontal markings, also work needed for vertical markings, cleaning, mowing grass, snow removal, etc.).
It has to be noted that MIR assume a worst-case scenario, where there is high insolation, corresponding to measured at 35° latitude, and unlimited supply of nitrogen dioxide (Carter, 1994). Such conditions are present in the Mediterranean basin even if majority of the affected area is not located as far south as was used for MIR conditions.
During the episodes of high ozone or when weather conditions favour formation of tropospheric ozone and its retention off-shore and return to the land, the removal of tropospheric ozone precursors like those present in solventborne road marking paints appears critical.

3. Results and discussion

3.1. Influence of solvent choice on ozone formation potential

Firstly, the profound influence of solvent choice on ozone formation potential has to be illustrated. One can take the strictest VOC emission rules for road marking paints in Europe: In Scandinavia, maximum VOC emissions cannot exceed 2%, which effectively eliminated solventborne road marking from that region. However, the 2% emissions do not specify what solvent can be used. Assuming the same VOC limit of 2%, from 1 kg of applied road marking paint can be potentially produced between 7.2 g and 77.6 g of ozone, a tenfold difference, as shown in Table 1. Ethanol, which is almost always added to waterborne road marking paints, does have a noticeable tropospheric ozone formation potential despite its relatively low toxicity. Furthermore, one has to remember that the coalescent (Texanol®) is not a VOC according to European regulations (it is a VOC according to the North American regulations) but it does evaporate, albeit extremely slow, and has an ozone-formation potential. A question arises how such a chemical should be treated.

Table 1

Solvents and possible different tropospheric ozone formation (assuming 2.0% VOC)

Solvent	MIR	Ozone formation potential [g O_3/kg paint]
Methyl isobutyl ketone	3.88	77.6
1-methoxypropan-2-yl acetate	1.70	34.0
Ethanol	1.53	30.6
Methyl ethyl ketone	1.48	29.6
Butyl acetate	0.83	16.6
Texanol®[(a)]	0.81	16.2
Acetone	0.79	7.2
(a) Coalescent, which is not a VOC according to the regulations; added typically at 1.5-3.5%, depending on the binder type and content. Here, it is assumed to be at 2.0%.		

3.2. Solventborne road marking paints and potential of ozone formation

Solventborne road marking paints are being commonly used, because of their availability, low price, and ease of applications, even if their durability is not the highest. In areas where the use of toluene, an aromatic solvent, is not specifically banned or restricted by law, it is being used. Some of the advantages of using toluene as a solvent for road marking paints were recently discussed by us (2016).

We have done our analysis on four solventborne paints that are used in the Adriatic sea basin and included a typical waterborne paint for comparison. The compositions of volatiles disclosed in the SDS and the potentially formed ozone are listed in Table 2.

Solventborne paints used in the western Balkans (paints 1 and 2) contain toluene as an exclusive solvent. Therefore, potential of ozone formation is very high, reaching even 958 g per kg of applied paint. With typical spreading rate of 600 g/m² and line width of 15 cm, there is a possibility of formation of up to 86 g of ozone per linear metre of applied marking! A report (Tebert, 2011) estimated the usage of solventborne paints usage in Croatia in 2006 at 1069 tonnes. VOC emissions from such quantity of paint would be 257 tonnes and the emitted VOC could lead to formation of over 1000 tonnes of ozone with paints 1 or 2! This calculation only demonstrates the enormous quantities of emissions and potential of ozone formation in the worst case scenario and it ought to be understood that weather conditions profoundly influence the actual formed tropospheric ozone. In case of paint 3, addition of acetone as co-solvent leads to meaningful lowering of ozone potential formation

Solventborne paint produced in Italy are toluene-containing (paint 4) or aromatic-free (paint 5) systems. VOC emissions from such paints are equally large, but the amount of potentially formed ozone of aromatic-free paint 5 is significantly lesser. Hence, the estimated 5691 tonnes of solventborne paints annually used in Italy (Tebert, 2011) translates to emissions of 1366 tonnes of VOCs, which could lead to production of ozone between 1414 (paint 5) and 2745 tonnes (paint 4). One must note here that essentially all of Italy is a non-attainment area in terms of ozone pollution.

Waterborne road marking paint (paint 6) has VOC emissions of only 1.5% (according to the European regulations) and those VOCs can lead to formation of only 36 g of ozone per kilogram of paint. If all paints in Italy were switched to waterborne, emissions would be lowered to only 85 t of VOCs (94% reduction) that could yield up to 205 t of tropospheric ozone (83% reduction).

Table 2
Maximum tropospheric ozone formation from various paints (assuming 24% solvents)

		Paint system					
Solvent	**MIR**	**1**	**2**	**3**	**4**	**5**	**6**
Toluene	4.00	23.6%	23.9%	17.5%	11.0%		
Methyl ethyl ketoxime	1.58		0.1%	0.2%			
Butyl acetate	0.83	0.4%			2.0%	18.0%	
Ethyl acetate	0.63					1.5%	
Methyl acetate	0.07				4.5%		
2-butoxyethyl acetate	1.62					1.5%	
Methyl ethyl ketone	1.48					7.5%	
Acetone	0.79			6.3%	3.5%		
Methanol	0.67				1.5%		
Ethanol	1.53						1.0%
Butanol	1.88					1.5%	
Texanol®	0.81						3.5%
C14-C17 chlorinated paraffin	0.00				1.5%		
Ammonium hydroxide	0.00						0.5%
Water	0.00						19.0%
Maximum ozone formation [g O_3/kg paint]		**944**	**958**	**726**	**482**	**249**	**36**

It is extremely difficult – if at all possible – to measure what percentage of VOCs are converted to tropospheric ozone, because marking is frequently done after sundown and when ambient temperatures are not extremely high. However, in such cases, the solvents are migrating to the stratosphere, where they undergo decomposition — and often create even more harm to the global environment.

3.3. Viable solution

The use of waterborne road marking systems, particularly with glass beads furnishing extended durability, could lead to very significant decrease of VOC emissions and the levels of ground-level ozone. The decreases could be 27-fold when one compares the reduction in potentially formed ozone from toluene-based and waterborne road marking paints. Such reduction would translate to improved health of the application crews, the citizens, and our planet. Alternatively, one could use solvent-less systems; however, such systems are more expensive to purchase and apply and they may be an over-engineered solution for a plethora of roads. Road authorities and the applicators ought to consider the utilisation of readily available solutions that are less harmful for the environment.
It is obvious that the emissions from sources other than road marking materials are significantly higher. However, the contribution of road marking paints to the VOC emissions and their ozone formation potential can be easily lowered, which is particularly important in area prone to high ozone episodes and where the weather conditions generally favour the use of waterborne materials, notwithstanding their higher durability.

4. Conclusions

Solvents from road marking paints are VOCs and thus affect the formation of tropospheric ozone. Their influence varies depending on their decomposition pathways, climatic conditions, and the presence of other pollutants. Adriatic Sea basin, where summertime insolation and temperature are very high, is supporting formation of tropospheric ozone and indeed there are quite frequent episodes where the norms are exceeded significantly.
The use of waterborne road marking paints is a viable environmentally-friendly alternative to the currently used solventborne materials. Waterborne road marking systems are not only easy to apply and durable, but also have lower negative effect on our and our planet's health. Reduction of the possibility of tropospheric ozone formation may be

enormous: Whereas a toluene-based solventborne road marking paint can produce up to 958 g of ozone per kilogram of applied paint, waterborne road marking paint of better durability has the potential reduced 27-fold, to only 36 g O_3/kg.

EFFECTIVE FLEET MAINTENANCE PLANNING WITH THE AIM OF ACHIEVING ENERGY-EFFICIENT AND RATIONAL REALIZATION OF TRANSPORTATION PROCESS

Davor Vujanović[1]
[1] *University of Belgrade, Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, Belgrade, Serbia*

Abstract: The companies which own vehicle fleet for carriage of goods are considered in this paper. The main objective of considered companies is to accomplish all the planned transportation tasks while minimising transportation and maintenance costs in the opserved period, which leads to higher profit. In this sense, the influence of effective maintenance planning on the achievement of defined objective of observed companies is researched in this paper. For this purpose, a study was conducted in several observed companies in Serbia, in terms of existing maintenance planning. The conducted study shows which part of maintenance work is realized in own maintenance facilities of the companies, and which part in the external specialized vehicle service center (SVSC) in the region. In order to make a decision in choosing a SVSC, managers take in consideration the several different factors (criteria). Based on conducted survey, the paper defines the relevant factors that affect the mentioned decision when planning maintenance work. It has been found on which factors managers should pay more attention when making considered decision in order to become effective maintenance planning and to realise the given transport volume in an energy-efficient and rational way.

Keywords: maintenance planning, specialized vehicle service center, vehicle fleet, energy efficiency.

1. Introduction

The research presented in this paper deals with companies owning light commercial or heavy goods vehicle fleets. The transportation services bring profit to the observed companies. In order to maximize their profit, companies are dedicated to accomplish all planned transportation tasks in certain period, with minimizing transportation and maintenance costs.

One way to achieve defined company objective is achievement of an effective fleet maintenance management. Since vehicles represent mobile assets permanently in contact with environment, the external environment factors have influence on vehicle maintenance process and transportation process. In this sense, to achieve an effective fleet maintenance management it is necessary to simultaneously and jointly observe: the transportation process, the vehicle maintenance process and the environment (Vujanovic et al., 2012).

According to statement of many authors (Ashayeri et al., 1996), (Brandolese et al., 1996), (Dhillon, 2002), (Johnson, 2002), (Mobley et al., 2008), one of the most important activities within maintenance management is maintenance planning. In that manner, this paper tries to indicate an importance of fleet maintenance planning on energy-efficient and rational realization of transport process and thus on achieving defined objective of observed companies.

The maintenance planning activity involves planning of timeframes in which preventive and other planned maintenance interventions should be realized, planning of dedicated maintenance manpower needs as well as necessary spare parts and materials, along with the timing of their procurement (Ashayeri et al., 1996). Within fleet maintenance planning, managers make also a decision where to perform the required maintenance work, for each vehicle request. In this respect, managers can make a decision to perform the maintenance work in company's own maintenance facilities or externally in specialized vehicle service centers in the region. Managers make a decision to perform maintenance work in a specialized vehicle service center (SVSC) in the region in a case when companies do not own adequate maintenance facilities or when in required timeframe their maintenance facilities are unavailable.

Selection of a SVSC in the region where will be executed the planned maintenance work is a managers decision which is affected by many different factors (criteria). In order to make the right decision in choosing a SVSC in the environment by managers and thus to make fleet maintenance planning more effective, it is important to define relevant factors that play significant role in this decision. In this sense, this paper represents a conducted research with the aim of defining relevant factors that affect a decision of selection the SVSC in the region where planned maintenance work will be executed.

For this purpose, the paper is structured as follows. The chapter 2 describes the activity of fleet maintenance planning. Based on the conducted study in some companies in the Republic of Serbia, the existing fleet maintenance planning activity is presented in chapter 3. In chapter 4 a survey on defining the relevant factors influencing the selection of a suitable SVSC in the region is presented. Conclusions are given in chapter 5.

2. Activity of fleet maintenance planning

The maintenance planning is an activity that predetermines operations, methods, materials, tools, equipment, labor, required time and deadlines for performing maintenance procedures (BS3811, 1984). According to paper (Gits, 1994), the importance of properly maintenance planning is reflected in following: contributes to reduce the number of

[1] Corresponding author: d.vujanovic@sf.bg.ac.rs

unexpected breakdowns; contributes to reduce the number of disturbance in maintenance process; as result of delivering product on time, affects the reduction of lost customers number; through the adequately perform of preventive interventions, affects the reduction of repairs cost and retains the performance of technical system within projected values; through the use of Maintenance Plan contributes to reduction the costs of electricity, gas and water in the maintenance facilities; ensures the existence of adequately spare parts in the required timeframe. According to authors (Mobley et al., 2008), maintenance planning activity relates to the preparation of work that should be performed in the future.

The fleet maintenance planning is an activity that is carried out at the operational level of maintenance management. This activity is conducted the most commonly by maintenance managers or fleet managers. As shown in Figure 1, through the conducting of maintenance planning activity, it is necessary that managers take into jointly considerations: informations of own vehicles; informations of fleet operations (*Operational Plan-OP*); informations of own maintenance workers, equipments and capacities; legislation that affects safe road traffic, and environmental protection; vehicle dealers' conditions regarding the warranty period; recommendations of vehicle manufacturers in terms of preventive maintenance; locations and quality-of-service of SVSC in the region, quality-of-service of spare parts' and materials' suppliers; informations based on conducted analysis of fleet maintenance job.

In this respect, managers have to ensure and prepare all the conditions in form that planned maintenance work is carried out without disturbances and in aim with defined company objective. For each registered vehicle maintenance request, they make decisions about the following issues:

1) location of maintenance work realization (in the company's own facilities, or in a specialized vehicle service center in the region);
2) timeframe of maintenance work realization;
3) required workforce of particular professions and the quantity of certain spare parts and materials (if maintenance work will be performed in company's own facilities);
4) Measures that have to be implemented to avoid or decrease disturbances during the maintenance work realization.

In cases when companies don't have their own maintenance objects or when a suitable equipment or workspace in the existing maintenance object is missing, managers have to make a decision on appropriate SVSC in the region where to carry out planned maintenance interventions on specific vehicle. Moreover, managers make this decision in the cases when workers of required professions are unavailable, when adequate vehicle workspaces are unreachable, when existing equipment is defective, etc.

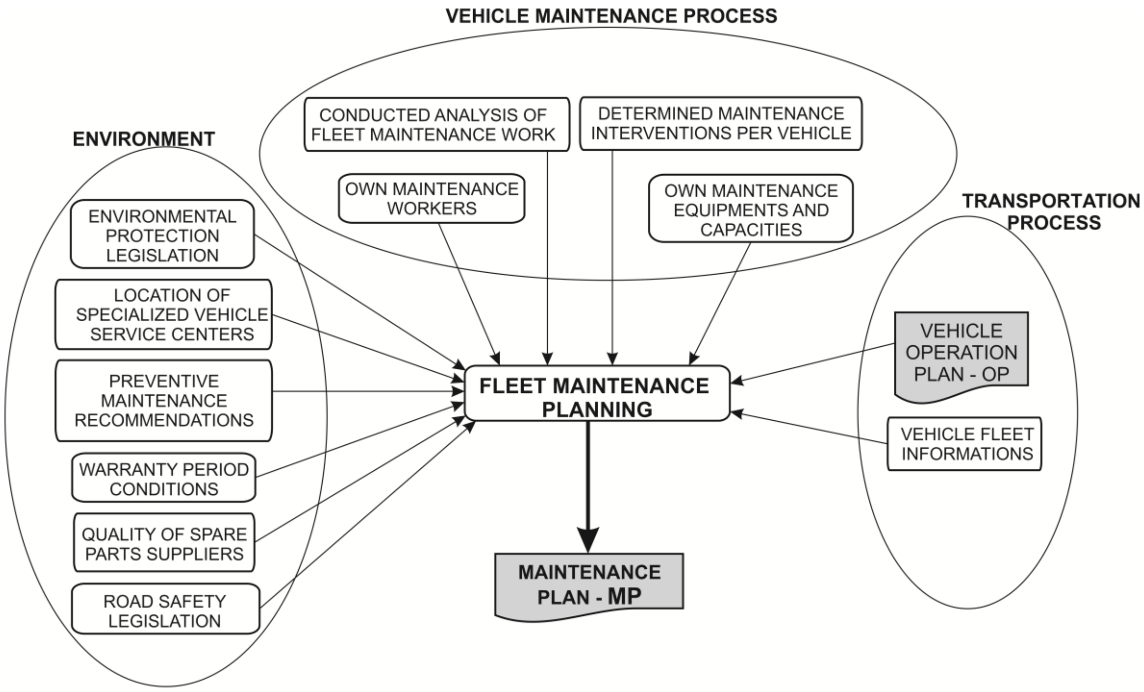

Fig. 1.
Position of fleet maintenance planning

Formalized form that describes the process of conducting of maintenance planning activity is represented by the document called *Maintenance Pla*n (MP). This document (Figure 2) represents a basic tool in the fleet maintenance management and the managers are in charge of filling this document adequately, while making the decisions on place and time of realization of specific vehicle maintenance interventions (Momčilović et al., 2007). The indicator *Maintenance Plan Realization* is the most important indicator of effective fleet maintenance management (Vujanović et al., 2012).

MAINTENANCE PLAN

		...	...		...	...				...	...	...	...

Fig. 2.
Preview of document Maintenance Plan (MP)
Source: (Vujanovic, 2013)

Effective maintenance planning allows managers to have an available vehicle from the most suitable *Construction-Operation* (CO) group for the implementation of transportation tasks in the required time. It has an influence on better cargo capacity usage per realized transportation volume which leads to an increase of fleet energy efficiency and decrease transportation costs (Kamakat and Schipper, 2005), (Ruzzenenti and Basosi, 2009), (Vujanović et al., 2010). Moreover, the effective maintenance planning affects the reduction of number of backup vehicles, for the actual transportation process. It decreases the total fleet size and makes the fleet more rational, which has an influence on decreasing the transportation and maintenance costs (Vujanović et al., 2013).

3. Fleet maintenance in some companies in Serbia

In order to analyze the current situation in some companies in Serbia regarding the fleet maintenance, a study in the period of the end 2015 to the first quarter of 2016 was conducted. Only the companies with own fleets dealing with freight transportation in Serbia were analyzed in the study.
The aim of study was to examine which part of maintenance work (in percent) is executed in own maintenance facilities of the companies, and which part in the external SVSCs in the region.
In Table 1 the analyzed companies in conducted study are presented. As shown in Table 1, the average fleet size of observed companies is 125 vehicles, and their average age is about 5.8 years. In average 82% of total vehicle number in the companies are out of manufacturer warranty period.

Table 1
An overview of analyzed companies with fleet data

Company name	Vehicle fleet size	Average vehicle age (in years)	Number of vehicles out of manufacturer's warranty
AKS Express Kurir, Ltd.	456	3.5	338
Banini, Inc.	4	10	4
BEX Express, Ltd.	292	10	292
Centrosinergija, Ltd.	104	1	10
City Express, Ltd.	218	6	196
Delmax, Ltd.	33	5	28
G4S Secure Solutions, Ltd.	106	8	106
Mercator-S, Ltd.	141	3.5	95
Milšped, Ltd.	51	7	51
Nelt Co, Ltd.	203	4.2	196
Nestle Adriatic S, Ltd.	2	5	2
Nordex, Ltd.	5	7	5
Pelexino, Ltd.	22	7	22
Veletabak, Ltd.	116	4	98

The most of the analyzed companies own a fleet up to 50 vehicles (Figure 3). More than 200 vehicles have 4 of the analyzed companies. As shown in Figure 4, the most common type of vehicle in the analyzed companies are vans of total permissible weight up to 3.5 tons, which makes 69% of the total number of vehicles.

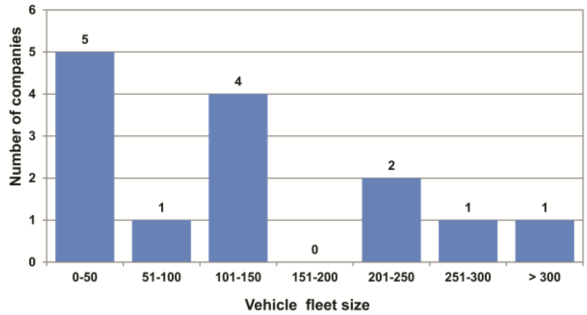

Fig. 3.
Vehicle fleet size in the analyzed companies

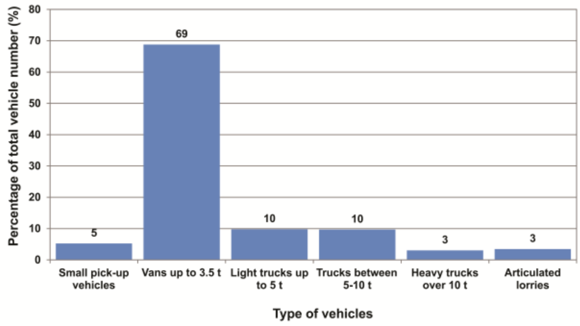

Fig. 4.
Share of vehicle type in the analyzed companies

According to conducted study, 8 analyzed companies don't have their own maintenance facilities, i.e. don't have their own workplaces for performing the maintenance interventions on vehicles (Figure 5). Only one company has more than 2 maintenance workplaces. This fact shows that managers in many of analyzed companies largely plan to accomplish the maintenance work in specialized vehicle service centers (SVSCs) in the region. In Figure 6, a relationship of maintenance work performed in SVSCs and maintenance work performed in companies' own facilities is shown. As shown in Figure 6, a significantly higher share of maintenance work performed in SVSCs have 11 companies. Only 2 of analyzed companies have a higher share of maintenance work performed in their own facilities during the observation period.

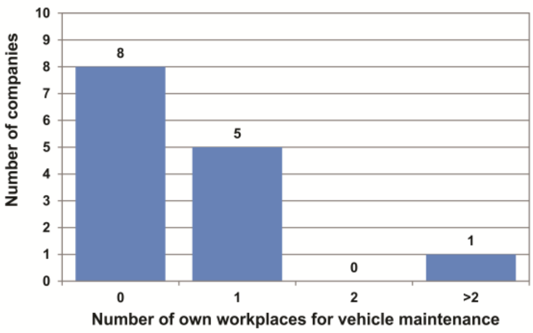

Fig. 5.
Number of maintenance workplaces in the analyzed companies

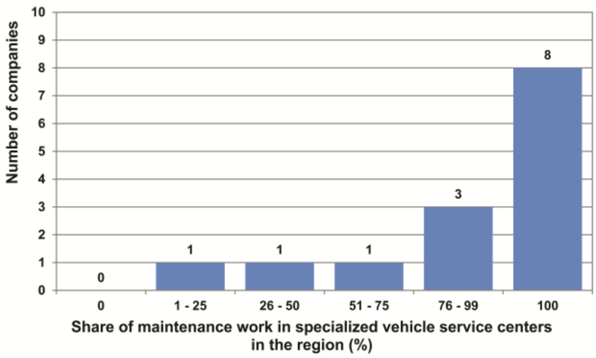

Fig. 6.
Share of performed maintenance work in SVSCs in the region vs. performed maintenance work in companies' own maintenance facilities

According to facts in conducted study, it can be concluded that managers of the considered companies very often make decisions on performing the planned maintenance work in SVSCs in the region. In order to effectively plan the fleet maintenance, among other things, managers have to make the right decisions about the selection of a suitable SVSC in the region where to carry out planned maintenance interventions on vehicle. The observed decision affects the energy efficiency and has an influence on rational realization of the given transportation process. In this respect, the right decisions about the selection of a suitable SVSC in the region contribute significantly to achieving of defined companies' objective.

However, managers take into consideration several different factors (criteria) while making mentioned decision. In this sense, it is necessary to define the relevant factors influencing the mentioned decision. In the next section of this paper is presented a conducted research on defining the relevant factors influencing the selection of a suitable SVSC in the region.

4. Research on defining the relevant factors

With the aim to finding the relevant factors that play an important role on managers' decision making in the selection of a suitable SVSC in the region, a research was carried out. For this purpose, an expert opinion survey was implemented. A survey involved 38 experts, of which 6 professors from the Faculty of Transportation and Traffic Engineering, University of Belgrade. The remaining 32 experts are transportation professionals with Master or Bachelor degrees in transportation engineering. All the experts involved in the survey are experienced in the area of vehicle fleet operation and maintenance. The survey was executed at the beginning of 2016.

During the survey, the experts were answered which factors in their opinion have a significant impact in the selection of SVSC in the region. On the basis of experts' responses in the survey and according to author personal experience in the observed field, in Table 2 the relevant factors were presented. As shown in Table 2, there are 11 factors that influencing significantly the decision making in the selection of suitable SVSC in the region where the planned maintenance work will be realized.

Table 2
Review of relevant factors influencing the decision making in the selection of suitable SVSC in the region where the planned maintenance work will be realized

Number	Relevant factors
1.	Maintenance Service Realization Costs in the SVSC
2.	Vehicle Travel Costs to the SVSC
3.	Payment Amenities for Maintenance Service granted by the SVSC
4.	Performed Maintenance Interventions' Quality by the SVSC (company’s experience)
5.	Respecting Agreed Timeframe by the SVSC (company’s experience)
6.	Performed Maintenance Interventions’ Speed by the SVSC (company’s experience)
7.	Location (Distance) of the SVSC
8.	Accessibility of the SVSC
9.	Service Network Development Level of the SVSC
10.	Size of the SVSC
11.	Specialization and Facility Equipment of the SVSC

Taking into consideration the factors 5, 6, 7, 8 and 9 during the maintenance planning activity allows the availability of vehicles of the most suitable construction-operation group in the state "ready for operation" in the necessary timeframes for transportation process realization. It affects better cargo capacity utilization by performed transportation volume, which has an influence on the increasing energy efficiency.
For ensuring a rational number of vehicles necessary for transportation process, it is required to take into consideration the factors 4, 5, 9, 10 and 11.
Taking into consideration the factors C_1, C_2 and C_3 has a direct influence on reduction of maintenance costs.
In order to achieve effective maintenance planning, managers should respect all relevant factors while making a decision of selection a suitable SVSC in the region where the planned maintenance work on vehicle will be realized.
Defined factors represent a good basis for the development of a multiple criteria decision-making model for the selection of SVSC in the environment, within maintenance planning.

5. Conclusion

Effective maintenance planning plays a significant role for achieving defined objective of the observed companies. For effective maintenance planning, managers should take into jointly considerations the requirements of transportation process, vehicle maintenance process, as well as environment.
During the maintenance planning activity, managers have to make a decision of selection the locations for maintenance work realization, among others. According to conducted study in 14 companies in Serbia, 8 companies don't have their own maintenance facilities, i.e. they don't have their own workplaces for performing the maintenance interventions on vehicles. In this respect, managers often make a decision on the selection of suitable specialized vehicle service centers (SVSCs) in the region where planned maintenance work on vehicles will be realized.
However, the mentioned decision is influenced by different factors. In order to define the relevant factors influencing mentioned decision, a survey was conducted. Based on conducted survey, managers have to pay more attention on 11 relevant factors while making decision on selection a suitable SVSC in the region. Respecting the relevant factors by managers, fleet maintenance planning is more effective which contributes to the achievement of defined objective of observed companies.
Further research will focus on development of a multiple criteria decision-making model for the selection of SVSC in the region.

Acknowledgment

The research in this paper has been realised within the project TR36027 named: “Software development and national database for strategic management and development of transportation means and infrastructure in road, rail, air and inland waterways transport using the European transport network models” supported by the Ministry of Science and Technological Development of the Republic of Serbia.

EFFECTIVENESS OF COMMUNICATION TOOLS IN ROAD TRANSPORTATION: NIGERIAN PERSPECTIVE

Jacob Adedayo Adedeji[1], Samuel Olugbenga Abejide[2],Mohamed Mostafa Hassan[3]
[1,2,3] *Sustainable Urban, Roads and Transportation (SURT) research Group, Central University of Technology, Free State, South Africa.*

Abstract: Continuous increase in death toll as a result of road accident is at an alarming rate. Recent World Health Organization (WHO) global annual report estimated that about 1.25 million people die in road crashes and Africa region as the highest contributor. This traffic fatality rate has, however, been associated with poor roads condition, drink-driving, over speeding, violation of traffic rules, and careless attitude of the road users. Over the years, various measures such as rehabilitation of poor roads and traffic regulations …etc., has been put in place to avert this predicament but the reverse is the case as death toll through road accident increases by years. Additional measures also include the use of traffic communication tools. Although various communication tools exist on the road, this ought to guide the road users and in a way avert the dangers upcoming; however, this is not the case. In Nigeria, various studies have been conducted to this regards but little or no attention is given to the road marking as a communication tool, thus, these three question remains for Nigeria road network; (1) Do these tools (especially, road marking) exist on roads where accidents are frequent? (2) Are these tools effective? (3) What is the understanding of the road users of these tools? Therefore, this study pertains to the effectiveness of the communication tools in road transportation by considering the Nigeria road features and views of the road users. Results show that the drivers have a good knowledge of these traffic communication tools but on an average of 92%, the road marking sampled are not available on the roads and have in one way or the other contributed to the fatality rate experienced. There is a need for stakeholder's interventions which include regular funding and schedule for routine maintenance with more focus on road marking.

Keywords: traffic fatality, traffic communication tools, road marking, traffic safety, Nigeria roads.

1. Introduction

1.1. Traffic Fatality Rate

Globally, road traffic crashes are a leading cause of death and the main cause of death among those aged 15 – 29 years (Agbonkhese et al., 2013; WHO, 2015). Traffic crashes have been blamed on poor roads condition, poor maintenance culture, drink-driving, over speeding, violation of traffic rules, and careless attitude of the road users. Considering the magnitude of death caused by traffic crashes, which is estimated at 1.25 million people per year over the last seven years, it was considered as one of the sustainability development goals. The goal's target is to reduce road traffic death and injuries by 50% by the year 2020 (WHO, 2015).

In view of this, various measures such as rehabilitation of poor roads, implementation of new traffic regulations, and the invention of traffic communication tools (such as; traffic signs, road marking, and traffic signals) were put in place. These measures have improved road safety to some extent. Nonetheless, the measures on global level didn't reduce the predicament rather it only place it on a flat terrain (WHO, 2015), yet the in case of Nigeria, it is on the increase (Adedokun, 2015; Odeleye, 2000; Ezenwa, 1986). As a result, all of these measures have been receiving an improvement in a way to meet up with the aforementioned sustainability development goal. Hitherto, little or no results have been achieved despite the improvement. Focusing on the aspect of traffic communication tools; which should serve as information dispersal to the road user, this information ought to guide the road users and in a way avert the dangers upcoming.

Although some of these tools exist on roads yet, their impact are not felt. Thus, these three question remains for Nigeria road network; (1) Do this tool (especially, road marking) exist on roads where accidents are frequent? (2) Are these tools effective? (3) What is the understanding of the road users of these tools? Therefore, the objective of this study pertains to the effectiveness of the communication tools in road transportation by considering the Nigeria road features and views of the road users.

1.2. Death Toll in Nigerian Roads

Nigeria road network is the largest in West Africa and the second largest in the Sub-Saharan Africa (Okezie, 2013), with an estimate of approximately 200,000 km in length; where 17% is owned by the federal, 16% state and the remaining owned by the local government (Nnanna, 2003). Likewise, Nigeria has a total vehicle population of 10 million vehicles. However, only 19% of the total road network is in good condition while others are either in fair or bad conditions. The fair and bad conditions have contributed greatly to the death toll rate in Nigeria, such that Nigerian road is rated second most deadly road in the world (WHO, 2015). Additionally, according to a report from WHO, Nigeria was adjudged the most dangerous country in Africa with 33.7 deaths per 100,000 population every year (Adedokun, 2015).

[1] Corresponding author: jadedeji@cut.ac.za

However, the problem of traffic fatality in Nigeria is not a new development as Ezenwa (1986) reported on the increasing trends in fatality rates for a period of ten years (1974 – 1983). In the report, within those periods, the number of accidents increased by 10.4% and injured cases increased by 43%. This trend, however, is not capsizing but rather on the increase (Odeleye, 2000), this is evident as recent report show that; 6,450 Nigerian lost their lives in traffic accident and also between 2009 - 2013, the size of small European city population (30,435 people) were killed in traffic fatality on Nigerian roads (Adedokun, 2015). Overall, based on best conservative estimated data, Nigeria is a country with a serious and growing road accident problem and about the worst in the world.

The major contributors to this traffic fatality rate on Nigerian road are, however, similar to those of the rest of the world. Yet, these contributors on a broader note can be categories under some basic factors such as; vehicle operator factors or driver factors, vehicle factors, road condition factors, and environmental factors (Bun, 2012; Agbonkhese et al., 2013). Although most safety studies concluded that driver factors (or human error) are the main cause of accidents (Agbonkhese et al., 2013) yet, it is not the only cause but rather other sources contribute to this factor.

Thus, various measures have been put in place such as; traffic regulation to solve the issues around vehicle operator factors, vehicle factors have also been tackled by some traffic regulations and improvement in the design of the vehicles such as anti-collision sensor, and little or nothing can be done with regards to the environmental factors as these concerns nature and in most cases beyond human control. However, the issue around road condition factors is way behind in resolving the fatality in Nigeria, as most Nigerian roads are still in fair or bad condition. Withal, even the ones in good condition still lack communication tools which as further contributed to the increase in fatality rate (Olaifa, 2013).

2. Traffic Communication Tools

According to Mathew and Krishna Rao (2007), road communication tools or traffic control device is a medium used for communicating between traffic engineer and road users, or mechanisms installed, placed or drawn on road or roadsides by the traffic engineers to communicate certain information to the road users. Furthermore, they are used to provide information to regulate, warn, and guide the road users in a traffic system (Ogunmola, 2013). Some of these tools include; traffic signs, road marking, traffic signals, and parking controls.

Furthermore, communication tools are usually the combination of linguistic and non-linguistic elements (Ogunmola, 2013) and are very important in reducing conflict and collision between the road users and road mishap; thus, their use is not an option to ignore. On the other hand, there is a need for the road users to properly understand these tools and strictly in vive the habit of obeying these tools (Agbonkhese et al., 2013). However, it must be noted that before the installation or positioning of communication tools takes place it should satisfy one or more of the following requirement such as; fulfilling a specific need, commanding attention from users, simple and should convey clear message, and providing adequate time for proper response (Mathew and Krishna Rao, 2007).

In accomplishing the task set before the traffic communication tools, there are various characteristics which need to be put in place for this mechanism to work. These characteristics include; Colour (commonly red, green, yellow, black, blue and brown), Shape (Circular, triangular, rectangular and diamond), legend (Symbols) and Pattern, thus, consistency is of concern as these help the road users to identify them easily (Kadiyali, 1987; Mathew and Krishna Rao, 2007). However, this is based on the fact that these mechanisms recognize the limitation of human (road users) involved, this talk more of the eyesight. Overall, it can be said that most traffic signs available abide by these requirements yet, their maximum impact on the road are not felt but is this the case of Nigerian Road?

2.1. Safety Feature

Traffic communication tools converse safety categorically in three main ways, which are; regulatory signs, warning signs, and informative signs. In-depth explanations on these categories are available in studies Horberry et al., (2004), and Olumide and Owoaje (2016). The various examples of communication tools aforementioned mostly fall under any or all of these three categories except with the exceptional case which is the work zone signs (Mathew and Krishna Rao, 2007). In Nigeria, the importances of these tools are understood such that; in Nigeria road safety strategy 2012, traffic communication tools are one of the strategic goals in improving road infrastructures (Federal Ministry of Works, 2013).

Globally, various researchers (Hulberty et al., 1979; Stokes et al., 1995; Makinde and Opeyemi, 2012; Ogunmola, 2013; Makinde and Oluwasegunfunmi, 2014) have conducted research on the effectiveness of these communication tools. According to Hulbert et al. (1979) and Stokes et al. (1995) in the USA and Kansas respectively, the road users basically misunderstood these tools. In Nigeria, studies showed that these tools are effective in their capacity but the Nigerian road users do not pay attention, rather these tools are seen as mere decorations on the roads (Ogunmola, 2013; Adeboye et al., 2014). Overall, it was, however, noticed that most of the studies concerning Nigeria are centered on the tools such as; traffic signs and signals, with little or no attention given to road marking as a traffic communication tools, thus road fatality continues to increase (Adedokun, 2015). Although the Highway Code of Nigeria entails the road marking as one of the major traffic communication tools, yet little study have put them into consideration.

2.2. Necessities of Road Marking

Speed mitigation devices include signage, road markings, and variable message systems, typically placed in advance of an upcoming hazard with the aim of initiating a change in driver behavior. In particular, signage and markings are widely used for the purposes of explaining road layouts and hazards because of their relatively minor costs in comparison to altering existing geometric layouts (Martindale and Urlich, 2010). Road marking, however, is any kind of device or material that is used on the road surface in order to convey official information. These markings make a vital contribution to safety by clearly defining the path to be followed and are used as communication tools on paved roadways to provide guidance and information to the road users (Federal Ministry of Works, 2013; Ozelim and Turochy, 2014; Rehman and Duggal, 2015).
Road markings can either be mechanical (cat's eye, botts' dots, rumble strips and reflective markers), non-mechanical (paintings) or temporary in nature. As in other communication tools, road markings should be uniform in order to minimize confusion and uncertainty about their meaning and efforts exist to standardize such markings across borders (Mathew and Krishna Rao, 2007; Rehman and Duggal, 2015). However, there are different types of road marking which include; longitudinal marking, transverse marking, arrow marking, oblique parallel lines, word marking, …etc (Federal Ministry of Works, 2013). Additionally, as aforementioned road markings can fall in all the categories of communication tools such as regulatory signs, warning signs, and informative signs.
In the aspect of regulatory signs, the stop paint marking (Figure 1a) at the end of an intersection communicate to the road users (motorists) to stop for a while and observe other vehicles before progressing. Additionally, road marking act as a warning sign in the case of rumble strips (Figure 1b) (also known as sleeper lines) serve as noise generators, also attempts to wake a sleeping driver or alter a driver to various upcoming hazards both by sound and the physical vibration of the vehicle. Transverse road markings as defined by Martindale and Urlich (2010) are used to assist in raising driver awareness of risk through perceptual optical effects, thus encouraging drivers to reduce their speed in anticipation of an upcoming hazard. Overall, road marking alters the road users with information such as the common zebra crossing line, which gives the pedestrians right of way as soon as it is stepped on. In addition, a study based on the USA over a period of twenty years has shown that road markings can reduce fatality by 13% (FHWA, 1994 cited in Grosskopf, 2001).

Fig. 1.
Road Marking (A) Stop paint marking and (B) Rumble strips (Pratt, 2015)

In South Africa, road markings are used on all surfaced roads (Grosskopf, 2001) however, this is not the case in Nigeria as the usage of road marking on roads is still lacking, although after the completion of newly constructed roads, they are mostly marked with road marking such as; solid white line, white broken line, single solid yellow line, lane direction change line, stop marking …etc. Nevertheless, the road markings on the existing ones are poorly maintained (Odeleye, 2000) and thus, the markings fade off and the roads are left without markings. Thus, as a result of their unavailability on most Nigerian roads, the road users do not put them into consideration when available rather, these markings are seen as mere road ornaments by Nigerian road users (Ogunmola, 2013; Adeboye et al., 2014). While on the contrary, because of their available on South African roads the drivers have become so accustomed to them that they tend to react to them without really thinking (Grosskopf, 2001).
Furthermore, in the case of Nigeria most researchers (Makinde and Opeyemi, 2012; Makinde and Oluwasegunfunmi, 2014) have blamed the lack of understanding the traffic signs and communication tools on the education level, yet Akpan et al. (2015) argues that educational background does not seem to correlate with the understanding of and compliance with road traffic signs. Overall, the studies further argue that these tools are too simple not to be understood by a layman or an illiterate; however, these tools seem not to be available on Nigerian roads (Figure 2), despite their enormous contribution to traffic safety.

Fig. 2.
State Road in Nigeria without road markings (Photo taken 29-01-2016)

Charlton and Baas (2006) published a study that evaluated speed change or speed maintenance methods to alter driver behavior, particularly to reduce their approach speeds to a hazard. In Nigeria, the recent security measures (Military checking point stops) taken to screen traffic users on roads in the saga of *Boko Haram* has rather rendered death to some lives than good due to poor visibility of the road blocks sign as well as the approach distance to road blocks in other to alert the driver speed to slow down. Furthermore, speed reduction signals and driver communicating devices are lacking on the Nigerian roads. For example an approach to a roundabout somewhere in the north eastern part of Nigeria has no approach caution signal to a roundabout (Figure 3).

Fig. 3.
Approach to a roundabout without any signal or marking device (Photo taken 29-01-2016)

3. Methodology and Data Collection

3.1. Description of the Study Area

The study was conducted in Nigeria with major emphasis on the North Eastern region since it is a major road mostly challenged by security hazards where both road users and pedestrians have high illiteracy mentality (UNESCO, 2012). Additionally, based on a recent report on traffic fatality in Bauchi state; 123 persons were killed and 1378 were injured in the year 2015, this is without the inclusion of the last three months which are more noted for traffic fatality (Udodiong, 2015). According to a study on causes of road accident in Bauchi state by Yero et al. (2015), the major causes of road accidents include; tire burst, fatigue, obstruction on roads, night journey, loss of control, speed violation, dangerous driving, bad roads, use of phone, and dangerous overtaking. However, it is worthy to note that speed violation and bad roads are the leading contributors to these accidents.

On the bad roads aspect, this has been attributed to limited road signs on the roads. For instance road, signs such as zebra crossings, playgrounds …etc., were unsatisfactorily marked and even lacking at some appropriate places like approach to schools, roundabouts, market areas etc. Most of the communities along the route were denied some useful road signs. The few road signs available are not visible to motorists and pedestrians. Motorists and pedestrians find it difficult to move safely within these areas. Furthermore, because of the busy nature of vehicles on the road, bikers, people especially children and aged found it difficult to cross the road. There is always heavy overcrowding of vehicles and pedestrians on the route.

3.2. Data Collection

The approach used to collect data involved the use of questionnaires defined by sample size specifying a given margin of error which will justify the population size of the total road users and provide a confidence interval of judgment (Gray, 2013). The method used in this research involved the use of questionnaires administered and completed by commercial drivers. Two hundred questionnaires were distributed amongst drivers in various inter-city motor parks in Bauchi, Jos and Gombe viz-a-viz Bauchi-Jos Park, Bauchi-Gombe Park, Bauchi-Yola Park and Bauchi-Kaduna Park and Yankari Park. The questionnaire used was made up of three sections; the first section classifies the personal experience of the drivers, the second section classifies the driver’s opinion and views based on road markings and the third section on traffic signs and signals. The first section was designed to give detailed information about the driver’s bio-data and personal experiences such as the age, gender, and educational background, how well they comprehend the traffic signs and signals as well as the road markings etc. The second section gave information about the availability and type of road markings present on the federal roadways …etc. while the third section assessed the understanding of traffic signs and signals by the drivers. The third section had fifteen multiple choice questions of different traffic signs made up of five warning signs and ten regulatory signs.

4. Results and Discussions

4.1. Demographic Characteristics of respondents

The study indicated that all the respondents (90%) were males and 10% females; this is because driving is a male dominated activity within the north-eastern route drivers. It was observed that females who drive normally do not drive long distances except for few and most females normally drive within the towns or cities. Most of the drivers (80%) interviewed were in the age range of 18 - 35 years (Table 1). The driver’s interviewed were all above the 18 years mandatory driving age in most African countries. As, results from another study indicated that very young drivers (under 19 years) and elderly drivers (over 54 years) face difficulties in understanding and recognizing traffic devices such as road signs (Al-Madani, 2000). The drivers interviewed were educated to some extent, as results show that majority of them (75%) were Junior and Senior high school graduates (Table 2). This implies that the respondents could easily read and write which is a basic requirement for obtaining a driving license in Nigeria. Thus, in this study, it is assumed that all respondents would understand road signs since they have driving licenses and accordingly have passed both the oral and written examinations for obtaining a driving license.

Table 1
Age Range of Respondents

Age of respondents	**Percentage (%)**
18 – 34	80.0
35 – 59	15.0
60 – and above	5.0
Total	100.0

Table 2
Educational level of respondents

Educational Level	**Percentage (%)**
Primary	60.0
Secondary	25.0
Graduate	5.0
Not Educated	10.0
Total	100.0

4.2. General Remarks on Road Signs and Markings

Knowledge of road signs and markings is not only a factor for road accident prevention. However, the application of the knowledge is a key to the essence of these communication tools. This is because road signs and markings convey messages in terms of words or symbols. Signs are, therefore, essential where special regulations apply at specific places or at specific times, where hazards are not self-evident (Al-Madani, 2000). In this study, result indicated that 95% drivers have some level of knowledge concerning road signs and markings while 5% don’t. The interviewed drivers had different driving experiences with the majority of them (45%) having over 6 years driving experience, especially the commercial bus drivers and this shows that they were not novice drivers. It also implies that they have higher class driving licenses and thus, they should comprehend road signs and markings better.

According to Brachacki et al. (1995), year of driving experience helps in proper identification of road signs. Furthermore, Al-Madani, (2000) observed that there exist significant differences between novice and experienced drivers in observing and understanding road signs. This was also confirmed with the exception of drivers with over 10 years of experience (25%) comprehend significantly better than less experienced drivers (Al-Madani & Al-Janahi, 2002). The drivers interviewed belong to various drivers' unions in exception of 10% private car drivers and 10% truck drivers. The unions include the National Union of road Transport Workers (NURTW) (30%), and Bauchi Co-operative Commercial Driver union (70%).
The result also indicated that the common road sign was the speed bumps; 100% of the drivers observed that the roads were in very poor condition due to reduced shoulder and excessive increase in speed bumps on the federal highway resulting in increasing mortality growth. Thus, according to the drivers majority of the road markings (average 91.7%) were not available on the roads as well as the road signs except for few as seen in Table 3.

Table 3
Road Marking Survey

Road Marking	**Available**	**Percentage**	**Not Available**	**Percentage**
Solid White line	60	30	140	70
Single Yellow Line	10	5	190	95
Double Solid Yellow Line	0	0	200	100
White Broken Line	60	30	140	70
Yellow Broken Line and Solid Line	0	0	200	100
White Line-Stop Line	0	0	200	100
Pedestrian Crosswalk	0	0	200	100
Yellow Painted Island	0	0	200	100
Lane Direction Change Line	20	10	180	90
Average	16.7	8.3	183.3	91.7

4.3. Recognition and Application of Road signs and Markings

The ability of drivers to recognized road signs and apply them are the main contributing factors in reducing potential dangers associated with road usage. According to the majority of drivers (90%), mentioned that most of the accidents occurred in communities along the route. However, they could not link it to the negligence of road signs but the occurrence of accidents in communities especially knocking off pedestrians resulted from the reduced shoulder and sudden breaking speed on approach to speed bumps negotiation; knocking down pedestrians and even running into residential buildings close to the roads. This is because driving within a speed limit in town (< 50 km/hr.) when followed should allow drivers to control their vehicles. Encountering road signs about 100 m ahead before seeing the signpost signal drivers to prepare adequately and comply with the sign.

4.4. Challenges of Traffic Communication Tools Along the Routes

Road users face some level of challenges in conforming to the road signs and markings. The result from the study indicates that some of the road signs were covered with leaves of trees along the edge of the road and some have faded off due to the wearing of the paint used. Therefore, drivers could not see what situation is being displayed on the road sign. More so, the conspicuity of some road signs was questionable, as they were blurry and not easily recognizable. In addition, reflectivity, size and placement of road signs were some challenges and the respondents assert that some of the sign posts were not reflective in the dark. The standard guideline for placement of sign post is about 100 m from the situation being shown. Some drivers were of the view that, some road signs were too close to the situation. These situations even pose a risk to them since they normally drive into the situation without any conscious preparedness.

4.5. Road Safety Interventions

Road safety challenges in developing countries such as Nigeria are enormous. However, practical and effective interventions can be implemented to reduce road safety menace. Interventions such as wearing a seatbelt correctly can reduce the risk of road fatalities. Actions such as training of drivers on road safety should be coordinated among the stakeholders for effective results. Additionally, adequate fund should be set aside for routine maintenance which should encompass the repainting of the road markings. Overall, there should be a strong political will from the government for enforcement of road safety measures and capacity of drivers should also be built for the sustenance of interventions.
In addition, it is paramount for all road owning agencies (which in the case of Nigeria includes the federal, state and local governments) to devise a cyclic process for maintenance/ repairing of the road markings, according to their time cycle. Overall, the following guides can help in improving the conditions of road marking on Nigeria roads; firstly, ascertain the total length of road markings to be maintained and this can be done by each of the road owning agencies in Nigeria. Through the projected length, the cost of maintenance can be estimated. Secondly, the quality of the paints to be used must be according to the international recommended standard and the newly improved materials which

improved nighttime visibility should be considered. Thirdly, the function of each road marking must be checked if effective or not and finally, the specification standard of the application must be adhered to as this talk more about quality control. Once these guidelines are put in place one should expect a functional and safety enhance road markings on Nigeria roads.

5. Conclusions

Road signs and markings are very important traffic regulator devices. Neglecting road signs and markings pose potential dangers to both drivers and pedestrian. Different road signs and markings are identified along the route examined the majority without posted notices. Hump ridge ramps are dominant among the road situations for controlling speed in town, as it is more effective than the speed limit warning sign post. However, drivers are aware of the road signs and their importance but most of the drivers do not make any conscious effort to abide by the road signs. Along the route examined, some of the road signs are not conspicuous, not reflective enough to catch the eyes of drivers and their placement were covered with objects and defaced. Thus, the roadsides should be frequently cleared about 3 meters from the road.

Furthermore, the stakeholders involved in road sign designs and traffic regulations such as the Federal Highway Authority should be adequately resourced for the maintenance of road signs along the route and increase the length of the shoulder. In addition, symbolic road signs are easily remembered thus proper placement of these signs within the cities and travel route should be done to reduce mortality rates.

SESSION 9: ROAD TRAFFIC AND TRANSPORT RESEARCH - MANAGEMENT AND POLICY ISSUES

MODELLING WEEKEND TRAFFIC WITH WEATHER CONDITIONS USING VARIOUS EQUATION TYPE AND DIFFERENTIAL EVOLUTION ALGORITHM

Erdem Doğan[1], Ali Payıdar Akgüngör[2], Ersin Korkmaz[3]
[1,2,3] Civil Engineering Department, Engineering Faculty, Kırıkkale University, Kırıkkale, Turkey

Abstract: In weekends, amount of passenger car traffic is usually higher than weekday because of the activity-based traveling on some highways. Forecasting of this traffic, might help to local authorities to take safety precautions decisions on a road segments. This study aims to compose models to forecast weekend traffics using weather conditions and average weekday traffic variables. For this aim, two main models were composed: The Saturday traffic model and the Sunday traffic model. The Saturday traffic model variables are mean weekday daily traffic, maximum temperatures of Saturday and precipitations. The Sunday model is a linear model with only one variable: the predicted traffic values from the Saturday traffic model. In the modeling Saturday traffics, six-month (from January to June) data, which belongs to year 2015 and Ankara–Kırıkkale highway in Turkey, were used and 2014-March data were used for testing the models. The used temperatures were normalized and the precipitations data were involved as logical (0 or 1) inputs in models. To find best equation type for Saturday traffic model, four various equation forms were selected: (1) Linear, (2) polynomial-1, (3) polynomial-2, (4) multiplicative equation from. The linear and polynomial-1 have three, multiplicative has four, and polynomial-2 equation has five coefficients need to be determinate. Differential evolution algorithm was utilized to determinate best fitted values for these coefficients. Performance of the models were calculated using mean square error and coefficient of determination. The model with the polynomial-2 equation has minimum errors for the modelling stage and R^2 value is around 0.80. The model with the polynomial-2 showed the best performance on testing stage (R^2=0.96). These results show that the weekend traffic is related to weather conditions and it can be modeled convenient equation form and differential evolution algorithm.

Keywords: traffic forecasting, weekend traffic, weather conditions, model development, differential evolution, Turkey, Kırıkkale.

1. Introduction

The weather condition has an important effect on road user decision for traveling or not. Therefore, it needs to consider as an input variable in traffic modelling. For example, (De Palma and Rochat 1999) took a poll to understand the users' behavior with respect to transportation issues. The survey results showed that about 40% of respondents thinks that weather conditions have a significant influence on their decisions about traveling. Even if significant amount of traveler decides to not use roads, the road system users are still affected from adverse weather conditions. Therefore, the policymakers need solid strategies to control road systems in such events. Nowadays, advanced traffic management systems (ATMS) are applied to highways to use these strategies (Zhang, Holm, and Colyar 2004) . But these systems need information about traffic variations in future. For this reason, traffic forecasting is an important process to inform road users, ATMS and local government units. These information requirements have been pushing researchers to develop traffic forecasting models.

Some research reported about weather effect on traffic characteristic and user decisions. The first research about the weather and traffic was started with (Tanner 1952). (Hanbali, Rashad M. 1993) studied about snow storm and traffic volume in United Stated. They reported that snow storm might decrease traffic volume up to 56% depend on severity of storm. (Keay and Simmonds 2005) reported that the traffic volume decreases 1.35% in winters and 2.11% in springs. (Kilpellainen and Summala 2007) researched about weather forecast and driver choose about traveling. Their result suggests that prevailing road weather conditions are more dominant than weather forecasts for on-road driving behavior. The other research about the effect of weather conditions are (Andreyl and Olley 1990; Changnon 1996; Hall and Barrow 1988; Ibrahim and Hall 1994; Knapp and Smithson 2000).

The weekend traffic is mostly consist of activity-based travel, therefore it has different characteristics (Chandra R Bhat and Gossen 2004). This phenomenon tends researches to investigate about activity-based travel and demand models (C R Bhat and Misra 1999; Bowman and Ben-Akiva 2000; Hunt and Patterson 1996; Mallett and McGuckin 2000). These researches tried to understand the traveler choice of destination, travel modes, etc. Unlike these researches, this study is trying to develop forecasting model of daily activity based traffic to help policymakers to plan traffic control regulations.

Traffic forecasting models can be categorize into four class (Van Lint and Van Hinsbergen 2012). These are naïve, parametric, non-parametric and hybrid. Naïve model approaches are simple models and estimates future traffic with using historical average traffic data. Parametric approaches are model based techniques and they use mathematical or statistical equations (Wang, Papageorgiou, and Messmer 2006). The non-parametric model approaches utilize intelligent algorithms such as artificial neural networks (Habtemichael and Cetin 2015). On the other hand, hybrid models are implementation of the three mentioned approaches. (Vlahogianni, Karlaftis, and Golias 2014) summarized the most of the traffic models, if reader wants to more information. Most of the traffic forecasting attempts above in literature used time series techniques so they mainly utilized previous forecast results to estimate following traffic.

2. The traffic volume and weather data

This study used traffic and weather data of 2014 and 2015. The Republic of Turkey General Directorate of Highways (GDH) has been collecting the traffic volume data at continuous count sites since 2009. The traffic data was taken from highway between Ankara (capital) and Kırıkkale by using GDH data. In the weekends, the passenger-car traffic usually increases because of activity-based travelling in this highway. The accessed data from the count site consist of passenger-car volume between January and June in 2015 and March 2014. Between this time period, 25 average daily weekday traffic (DwdT), daily Saturday traffic (DsatT) and daily Sunday traffics (DsunT) were used to compose the models and March data were used for testing. The fluctuation of mean weekday, DsatT and DsunT via time is given in Fig.1. The daily traffics have a tendency to increase in observed time period.
The daily traffic of the observed time period is given in Fig 1. The DwdT were computed to sum weekdays (Monday to Friday) daily traffic and divide the sum of weekday traffic to number of weekdays. The DwdT is generally lower than DsatT and DsunT has usually highest traffic over observation period.

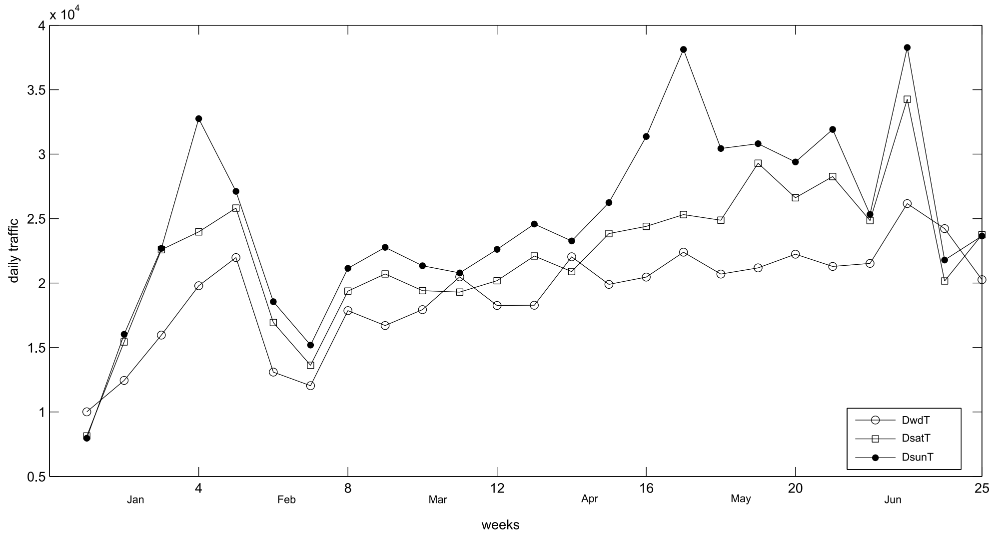

Fig. 1.
Daily (Sat. and Sun) and average daily (weekday) traffics from January to June

The temperature data were taken from (Http://www.havadurumu15gunluk.net/ n.d.). The highest temperature (H-tmp) of Saturdays and weather conditions with daily traffic of each Saturday's is shown in Fig. 2. In the observed time period, there were 11 rainy/snowy Saturday from 25 weekends and the H-tmp variated from -5 °C to 26 °C. The DsatT, the green line in Fig. 2, has tendency of increase and it is also obviously affected from temperature change. In the first 7 weeks the H-tmp mostly under 10 °C and DsatT is highly depended on H-tmp in these weeks as seen from Fig 2. After this 7 weekends period, the DwdT increases with linear trend. The precipitation also affects the DwdT to decrease in some of the weekends. In fig 2, at weekend 17 to 18, the H-tmp seems almost same but DwdT decreases in weekend 18.

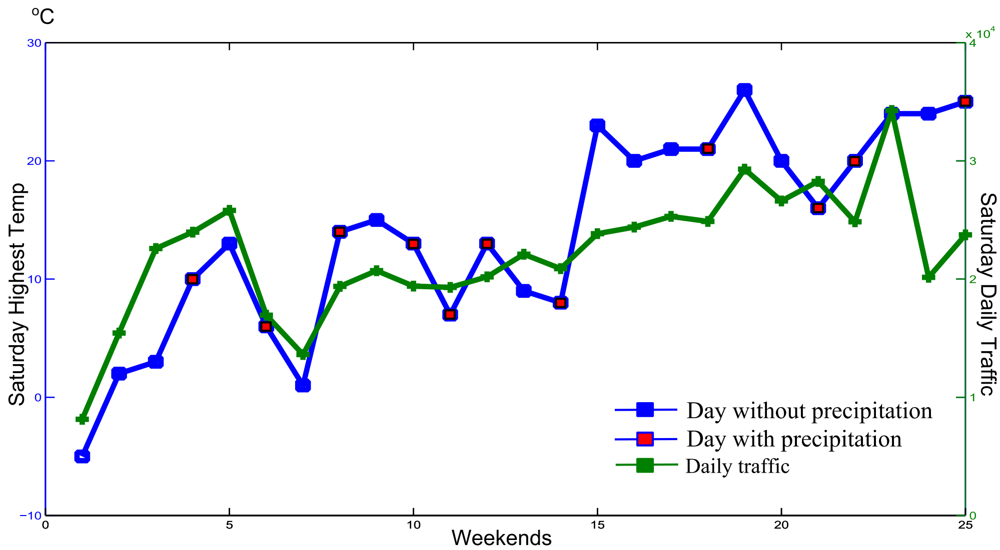

Fig. 2.
The Saturday's daily traffic values with temperatures and weather conditions

$$x_{norm} = \frac{x_{real} - x_{min}}{x_{max} - x_{min}} (x^{upper} - x^{lower}) + x^{Lower} \quad (1)$$

Where;
x_{norm} : Normalized value.
x_{real} : Real value.
x_{min} : Minimum value.
x_{max} : Maximum value.
x^{upper} : Upper value for normalization.
x^{lower} : Lower value for normalization.

The data normalization process simplifies the modelling so the temperature and traffic data were normalized with using Equ.1. For temperature, x_{min} and x_{max} were selected -15 °C and 40 °C; for the daily traffic x_{min} and x_{max} were selected 0 veh/day and 50000 veh/day, respectively. For both temperature and traffic data, x^{upper} and x^{lower} values, were selected 0 and 50000.

3. Weekend traffic forecasting models

Two different models were developed to forecast weekend traffics: The Saturday Traffic Model (SaTM) and The Sunday Traffic Model (SunTM). Four forms of equation were used to develop SaTM: (1) Linear, (2) polynomial-1, (3) polynomial-2, (4) multiplicative equation. In all forms, DwdT, normalized highest temperatures (H-tmp) and the rain/snow condition (RSP) were used as model inputs.

The linear traffic model is given in Equ. 2. There are three coefficients *(x_1, x_2, x_3)* needs to be determined in the model.

$$DsatT = x_1.DwdT + x_2.H - tmp + x_3.RSP \quad (2)$$

The polynomial-1 traffic model is given in Equ. 3. There are one exponential coefficients and two exponent needs to be determined in the model.

$$DsatT = DwdT^{x_1} + H - tmp^{x_2} + x_3.RSP \quad (3)$$

The polynomial-2 traffic model is given in Equ. 4. There are three coefficients and two exponent needs to be determined in the model.

$$DsatT = x_1.DwdT^{x_2} + x_3.H - Tmp^{x_4} + x_5.RSP \quad (4)$$

The multiplicative traffic model is given in Equ. 5. There are two coefficients and two exponent needs to be determined in the model.

$$DsatT = x_1.DwdT^{x_2}.H - Tmp^{x_3} + x_4.RSP \quad (5)$$

The RSP is the logical input and if there is rain/snow, it will take “1”. Otherwise it takes “0”. Therefore, this study did not use exponent with RSP.

The Sunday and Saturday traffic relation is understated from observation of Fig 1, and Sunday traffic consisting mostly return home traffic and it is not affected from weather unless extreme weather conditions. Therefore, the Sunday traffic model (SunTM) were composed with SaTM model estimation with linear equation form as given in Eq. 6. The linear regression was used to determine the x_1 in Equ 6.

$$DSunT = x_1.DsatT \quad (6)$$

Differential evolution (DE) were used to optimize the coefficients and exponents. DE is a heuristic technique for searching optimum parameters of functions (Storn and Price 1995, 1997). DE can give approximate results in non-linear and complex optimization problems. The fundamental steps of DE are initialization, mutation, crossover and selection (Kenneth Price, Rainer M. Storn 2005) and other information were illustrated in Fig 3. The population size (NP), weighting factor (F) and crossover ratio (Cr) are important parameters and they need to be set properly for problems. The F is need to be between 0 and 2, the CR is need to be between 0 and 1. In this study, F and Cr values were determined after a search process. In this process, all possible combination of Cr and F were tried with 0.1 increment. All of the combinations were also tried 30 times to be sure bout not missing the best combination.

Population consisting of D dimensional real-valued vectors. In our study, this vectors consists of the models' coefficients and degrees. The population for the polynomial-1 traffic model is given in Equ 7 as an example.

$$Pop_g = \begin{bmatrix} x_{1,1} & x_{1,2} & x_{1,3} \\ . & . & . \\ . & . & . \\ . & . & . \\ x_{12,1} & x_{12,2} & x_{12,3} \end{bmatrix} \quad (7)$$

The NP selected 4 times of the vector dimension, so there are (NP = 4x3 = 12) vectors used in polynomial-1 DE population (Equ. 7) . DE changes population vectors at each generation (g) with the vector which has better performance than previous vectors.

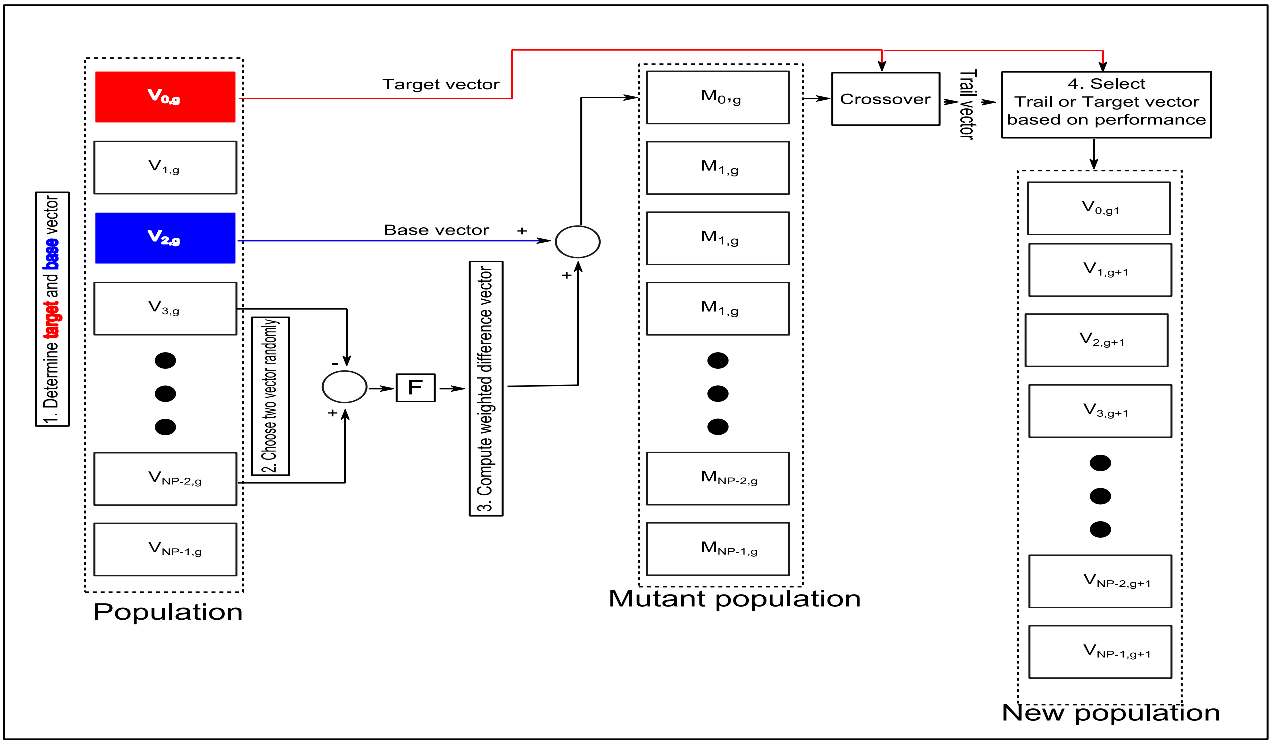

Fig. 3.
Differential evolution steps

4. The results and discussion

The traffic models' coefficients and degrees were given in Table 1. It is being understood from values of x3, x5 and x4 in Table 1 that the snow and rain decrease daily traffic approximately 2000 veh/day in study field. The Polynomial-2 model is given highest R^2 value and it is 0.80. The rest of the models R^2 values were very close to each other and the MSE are also close to each other for these three models as illustrated in Fig 5. The model degrees were settled between -1 and 1. The DwdT coefficient (x_1) is higher than x_2 for the linear model in Table 1.

Table 1
The Saturday traffic models' coefficient and exponents

	R^2	x_1	x_2	x_3	x_4	x_5
Linear M.	0.77	0.9857	0.1666	-2060		
Polynomial-1 M.	0.77	0.9927	0.8463	-2064		
Polynomial-2 M.	0.80	151.34	0.5305	$-7.58.10^7$	-0.965	-2526
Multiplicative M.	0.77	2.2980	0.7297	0.1998	-2066	

The SunTM was developed with linear curve fitting with MS-Excel. The R^2 value is about 0.84 as seen from Fig 4.

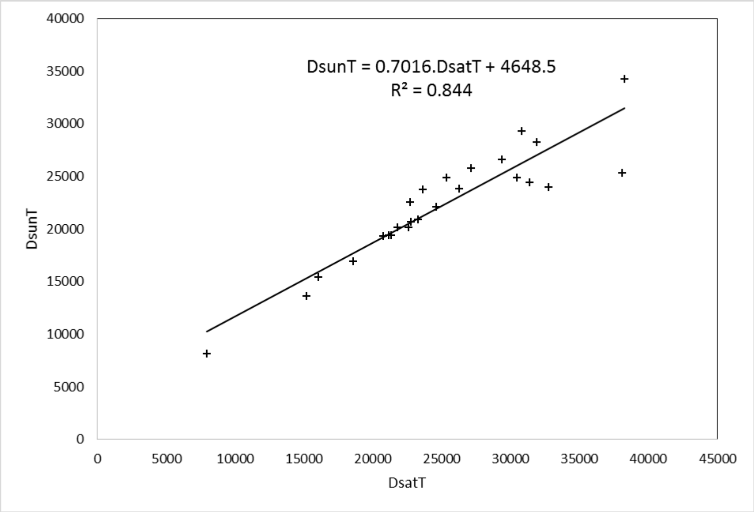

Fig. 4.
R2 value of SunTM

Differential evolution algorithm is powerful optimization technique but it needs to work with proper parameters. The Cr and F values were determined after the trail process. The CR values will be between 0 and 1 and the F values will be between 0 and 2. Therefore all possible combination, with 0.1 step, of F and CR were tried to find the best F and CR value. The results are given in Fig 5 and the best points/point is/are stated with red points. For linear and polynomial-1 model, most of the combinations produced best results and only the combinations near limits produced higher mean squared errors (MSE). The polynomial-2 model produced minimum MSE in CR=0.9 and F = 0.7 among all the models as seen from Fig 5. For multiplicative model, the best results were produced in the area with bounds of CR = [0.7 0.9] and F = [0.5 0.9] but the multiplicative form errors is higher than polynomial-2 model. Therefore, the polynomial-2 model was selected to create SaTM.

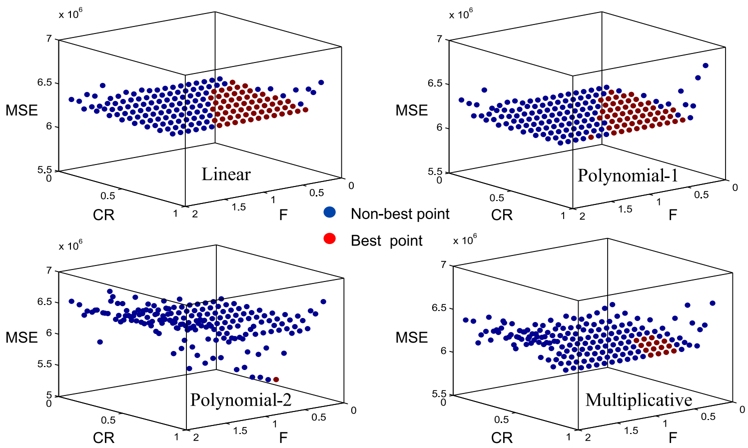

Fig. 4.
The MSE values for CR and F combinations

All models were tested with Marc 2014 traffic values. There were four weekend in Marc 2014 and the estimated and actual daily traffic values are compared using R^2. The linear model, Polinomal-1 and polinomal-2 models gave similar R^2 values and they were about 0.92. The multiplicative model gave best result among the other models and it was 0.95.

5. Conclusion

This study aims to develop weekend traffic forecasting model using weather conditions for Kırıkkale/Turkey. The parametric equations were used in models and DE were utilized to adjust the model coefficients and degrees. Two main type of models were adjusted: The Saturday model and the Sunday model. For Saturday model, four different equation type were considered and the polinomal-2 was showed better performance in Saturday model developing stage. On the other hand, the multiplicative model showed slightly better R^2 value. The Sunday model is a linear model and it has one coefficient and one constants. The variable of the model is the Saturday traffic estimation. These models have enough R^2 values and they are useful for forecasting weekend traffics. The developed models might be used by local traffic units to understand weekend traffic and to take precautions for safety issues. In addition, the ITS and ATMS needs future traffic information to control traffic and to inform road user for safer and comfortable traveling.

EVALUATION OF TRAFFIC CONGESTION AND RE-ENGINEERING SOLUTIONS FOR CENTRAL AREAS OF SOUTH AFRICAN CITIES: A CASE STUDY OF KIMBERLEY CITY

Dillip Kumar Das[1], Mmusho Keetse[2]

[1] *Department of Civil Engineering, Central University of Technology, Free State, Bloemfontein, South Africa*
[2] *Principal Engineering Assistant, Sol Plaatje Municipality, Kimberley, South Africa*

Abstract: Traffic congestion in and around the central business districts (CBD) of South African cities is a major challenge. Apparently, it is engendering undesirable consequences that include impeding vehicular flow, causing vehicular and pedestrian conflicts, escalating travel time, and frequenting vehicular crashes. So, using a case study of Kimberley city in South Africa, this study assessed the causes and degree of traffic congestion on the roads in and around the CBD area; and examined the impact of plausible re-engineering measures to alleviate the challenge. Survey research methods were used to collect data. Land use and urban functions influencing urban movements, road, and traffic scenario data were collected through physical and traffic survey at different selected road sections and junctions of the CBD area by following appropriate survey protocols. Besides, road user perception and travel behaviour survey were conducted among 208 (N= 208) road users by using random sampling process at important nodes of the city. Relevant empirical models were used to assess the causes and level of traffic congestion, and to examine the impact of re-engineering solutions on the current and forecasted traffic scenarios. Findings suggest an appreciable level of traffic congestion is experienced currently in some of the roads of the CBD area and the situation will be aggravated in future, specifically during the peak hours, whereas a number of roads are highly underutilised. Re-engineering solutions such as appropriate traffic assignment and modal split, i.e., traffic diversion ranging between 9.0% and 40.5% from different congested roads and restriction of plying of heavy vehicles on the congested roads during peak hours and assigning them to connected underutilised roads could ease traffic congestion, increase speed and reduce travel time and consequently enable optimal use of the majority of the roads in and around the CBD area of the city.

Keywords: central business district, traffic congestion, level of service, modal split, peak hours, traffic assignment.

1. Introduction

Traffic congestion has been a critical challenge in many cities across the world. It engenders a range of undesirable consequences that include negative economic impacts and environmental pollution (Rao and Rao, 2012; Sorensen et al., 2008; Wang, Gao, Xu, Sun, 2014). Many South African cities suffer from this challenge. Particularly, the central business districts (CBD) of a number of large and medium cities of the country are observed to be affected by the congestion challenges during different periods of the day. Kimberley city of Northern Cape Province of the country is a typical; example. The city, because of its unique physical, spatial, road network, economic characteristics, and requirement of mobility of heavy vehicles in addition to the normal city traffic experience critical traffic congestion challenge in its CBD area, particularly during the peak hours. Consequently, issues such as loss of economic benefits because of increase of travel times of vehicles in mining activities, delay in travel and change of travel pattern of local people for day to day activities, environmental pollution, and higher consumption of fuel and anxiety of people to travel top CBD area during business hours have emerged. In addition, experiences of different policy interventions such as creation of additional road infrastructure, Travel Demand Management measures, reinforcement of public transportation system, congestion pricing, encouragement of non-motorised transportation system, limiting parking facilities, etc., which have been tried in different cities of the world suggest that, these solutions have met mixed successes. Besides, they require creation of infrastructure, enforcement of certain constraints and restrictive measures and change in mobility behaviour, which is sometimes unacceptable by people and also incurs huge investment, making such projects economically unsustainable and socially unacceptable. This warrants acceptable and cost effective remedial measures to alleviate the traffic congestion challenges in the city. However, before evolving remedial interventions, it is necessary to assess the level of traffic congestion and reasons thereof; understand the perspective influence of the solutions that could assist in evolving strategies to meet the challenges. Therefore, the objective of this paper is to explore the causes and degree of traffic congestion on the roads in and around the CBD area; and examine the impact of plausible re-engineering measures to alleviate the challenge. The study was conducted by using Kimberley city of South Africa as a case study. A survey research method and relevant statistical and empirical models were used for the conduct of the investigation. . The study revealed that an appreciable level of traffic congestion is experienced currently in some of the roads of the CBD area and the situation will be aggravated in future, specifically during the peak hours, whereas a number of roads are highly underutilised. Re-engineering solutions such as appropriate traffic assignment and modal split, i.e., traffic diversion ranging between 9.0% and 40.5% from different congested roads and restriction of plying of heavy vehicles on the congested roads during peak hours and assigning them to connected underutilised roads could ease traffic congestion, increase speed and reduce travel time and consequently enable optimal use of the majority of the roads in and around the CBD area of the city.

2. Literature Review

Traffic congestion occur when traffic is delayed due to the presence of excess number of vehicles on the same portion of the road way at a particular time because the number vehicles trying to use the road exceeds the design capacity of the road (Department of transportation U.S., 2005, p. 1; Link et al. 1999, p. 9). As a result, there shall be long queues of vehicles, vehicles move slower than the normal or "free flow" speeds and at constant start and stop basis. It also results into delay in the overall traffic movement in a road network and the traveller fails move in a desirable manner (ECMT, 1999; Goodwin 2004; Levinson et al., 1997; Lomax, 1990; Lomax, Turner and Schunk, 1997; Taylor, 2003;). The traffic can be recurrent, non-recurrent and of pre-congestion state (Banjo, 1984; Chakwizira, 2007; HCM, 2000).

The reasons for traffic congestion can be grouped into three broad categories, such as, traffic influencing events, traffic demand and physical road features. Traffic incidents, work zones and weather are the traffic influencing events. Traffic incidents include vehicular crashes, breakdowns, debris in travel lanes, events that occur on the shoulder or roadside, etc. A construction activity on the roadway is the example of a work zone. Reduced visibility, bright sunlight on the horizon, presence of fog or smoke, wet, snowy or icy road way are the examples of poor weather. Traffic demand includes fluctuations in normal traffic, such as day to day variability in demand and special events. Physical highway features include road way physical and geometrical characteristics, poor traffic control devices and physical bottlenecks (capacity) of the road (Talukdar, 2013; United States, 2005, pp.1-2). There are several indicators, which are used to assess the level of congestion on the roads. One of the major indicators, which mostly favoured is the total amount of delay encountered calculated across all traffic from the difference between the actual speed encountered and free flow speed (Dft, 2000, 2000b; Dijker, Piet, Bovy, and Vermijs, 1998; Dodgson, Young, and van der Veer, 2002; Grant-Muller, 2005). It was believed to be advantageous in providing a better picture of how changing traffic levels and different policy packages can affect time lost to congestion, although delays are measured purely in terms of vehicle journey time and no allowances are made for differences in occupancy rates, values of time, or for additional factors, such as additional operating or environmental impacts that congestion can generate. Similarly, other simple measures relating to speed are also used to indicate congestion, particularly for a motorway environment (Grant-Muller, 2005). These indicators include mean journey times, variability of journey times, throughput (total number of vehicles per time interval that pass a point on the carriageway), queue lengths, speed differential between lanes and delay per hour/day (Graham and Glaister, 2004; Grant-Muller, 2005; Grant-Muller & Laird 2006; Noland and Polak, 2002). Besides, the congestion reference flow (a quantified measure of congestion for a link -junction must be considered separately) and the level of service (LOS) are other basic congestion measures applied widely in some countries like USA and Scotland, (Highways Agency, 1997; State-wide Planning Scenario Synthesis, 2005).

In the city level, the concentration of trip destinations in a small area – particularly CBD of the cities poses the challenge of providing large transportation capacity in limited physical space, while preserving the historical, political, cultural, economic and environmental heritage/values of the areas. It is evident that a larger share of trips flow to the city centres and they are found to grow exponentially with the city size. Simultaneously, CBDs are characteristically areas of high concentration of activities, and space is scarce. Thus, a dichotomy of high demand for transportation capacity in a geographic environment where space is limited does exist (Das and Keetse, 2015; Lascano Kezic, Durango-Cohen, 2012).

The various approaches such as supply management, land use management and transportation demand management have been resorted to alleviate the challenge (Ceylan and Bell, 2004; Gao and Song, 2000; Meyer, 2003; Stevanovic et al., 2013; Yang and Bell, 1998; Zanjirani Farahani et al., 2013). However, according to critics of this method, majority of the traffic jams are caused by accidents and events – not because of lack of capacity (STPP, 2001), so adding capacity to alleviate the problems becomes controversial on account of induced demand argument and the environmental and health effects of additional travel and land consumption (Gifford, 2005). Besides, supply management methods do little to mitigate congestion caused by non-recurring incidents. Land-use management describes the use of growth management, planning, and zoning to promote local density to encourage transit. Transit oriented development and high-density land use are both examples of this type of management. Similarly, land use management measures are criticized for two major challenges- that increased congestion is created by high-density development, and it takes long time to change land-use patterns and behaviors; they also doubt regarding the connection and causality between the two (Taylor, 2002). Transportation demand management (TDM) strategy institute largely financial incentives and disincentives to encourage motorists to use alternate routes, times and modes, or to defer trips entirely in order to reduce the demand for traffic facilities. TDM measures include congestion pricing, park-and-ride lots, high-occupancy-vehicle lanes, high-occupancy-toll lanes, employer commute option programs, telecommuting, alternative work schedules, and traffic calming measures. Of all the measures, congestion pricing tends to be both most effective and politically legitimate as a funding source (Gifford, 2005); however, due to the cost it places on drivers, it is one of the hardest methods to implement (Bass, 2008).

Besides, meticulous traffic design, use of technology – use of intelligent traffic system, Global Positioning System (GPS), inter vehicle communication and vehicle simulator, and variable message signs approaches are the other ways, which are used to reduce traffic congestion (Alterkawi, 2006; Chen, Yu, Zhang, Guo, 2009; Das and Keetse, 2015; Furth, Muller, 2009; Hardjono, 2011; Salicru, Fleurent, Armengol, 2011; Santos, Coutinho-Rodrigues, Current, 2008; Yin, Lam, Miller, 2004). Efficient vehicle routing, punctuality of routes and diversion of vehicles are also considered as other options to alleviate traffic congestion particularly in the congested urban areas. Although, some research has been done in this area, the focus is limited to a number of prototype problems, and the literature on vehicle routing –

segregation of vehicular traffic (modal split), optimal traffic assignment on different alternative roads and reengineering of the traffic system at the local level, and their impact on the road network – congestion and travel time under the effect of combination of the parameters is scarce (Cordeau, Laporte, Savelsbergh, Vigo, 2007). However, with increased growth of traffic flow, it is crucial to develop cost-efficient policies, which would alleviate traffic congestion and address negative externalities in terms of environmental impact and cost to the economy (Watling, Milne, Clark, 2012; Das and Keetse, 2015).

3. Case Study: Kimberley city

Kimberley City of South Africa was considered as the study area for this study (Figure 1). It is the capital city of the Northern Cape Province of the country and is situated on the latitude 28.7419°S and longitude 24.7719° E. It is known for its diamond mining activities. However, in recent years the economic functions of the city are changing because of the reduced mining activities. The city has a combined urban population of more than 225000 (Census, 2011). It has a total of 48 suburbs, which includes districts and townships and has a designated CBD. The city is connected to various major cities of the country, such as, Johannesburg, Pretoria, Cape Town, and Bloemfontein by national roads. It is also found that the city is about on an average of 800 km from some of the major cities in South Africa, i.e. Cape Town, Polokwane, Nelspruit and the town of Springbok. Apparently the city is the central point of the country from the road network point of view.

The CBD performs important urban functions of the city. It provides facilities for both commercial and administrative activities. Spatially, it is bounded by Quinn Street in the East, Cecil Sussman/Quinn Street in the North, Cecil Sussman/Bultfontein road in the west, and Lennox Street in the South, and is considered as the primary focused study area of the investigation. The arterial roads, which generally influence the traffic movement in the CBD area, are Long, Barkly, Bishop, Carter, Schnidtsdrif, Memorial and Transvaal Roads (Figure 1). As mentioned above these roads in an around the CBD area are under heavy pressure because of the combined movement of heavy vehicles in and out of the city and normal inter and intra city traffic resulting to inefficient traffic movement.

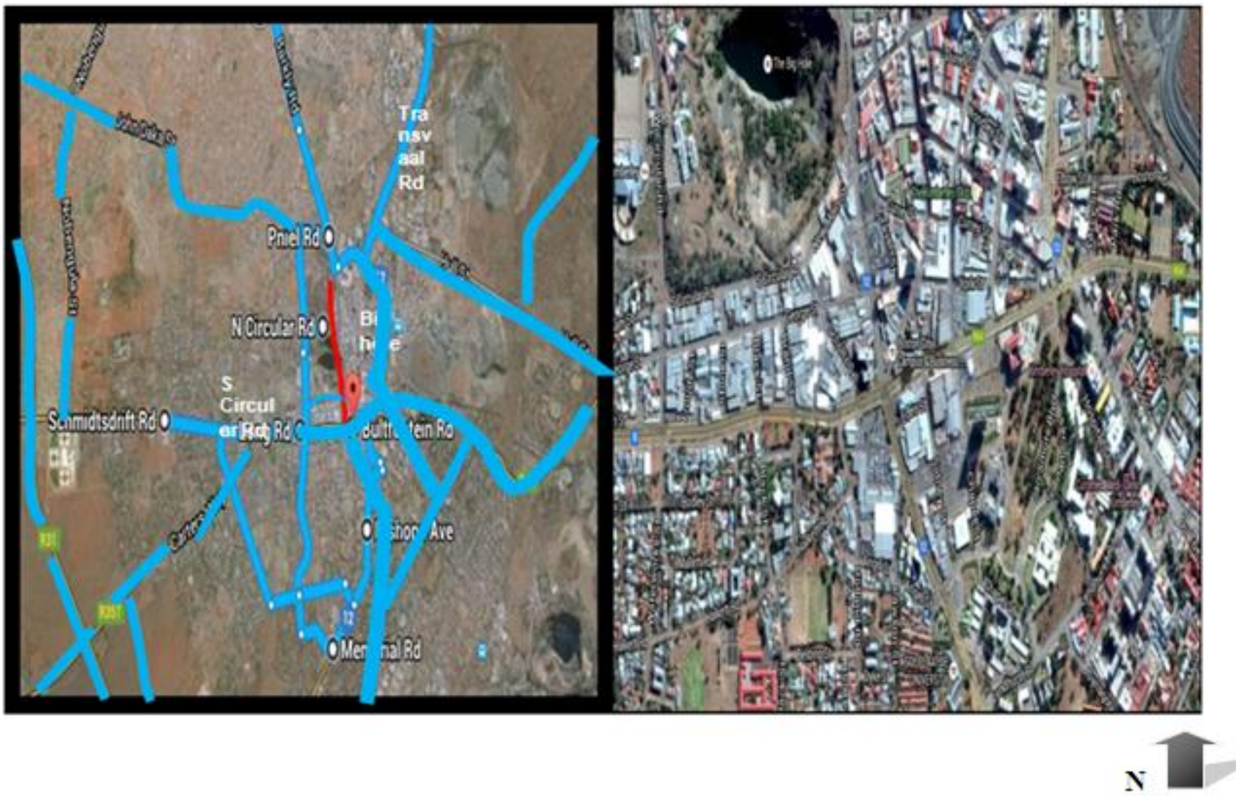

Fig. 1.
Road Network in the CBD Area of Kimberley City

4. Research Methodology

Since the investigation requires field data and road users' perception, a survey research method followed by quantitative analysis by use of statistical and empirical mathematical models suitable for analysing the traffic scenarios on the roads in and around the CBD area of city is observed to be most relevant (Kadiali, 2008). So, data were collected from primary and secondary sources. The primary data were collected from road user survey and traffic survey. The surveys were conducted by using established survey methodology applicable for transportation and traffic planning and design purposes. The collection of data from primary sources was essential because structured and up-to-date statistical data of important parameters with regard to traffic scenarios in the study area were not available. Moreover, the perception of road users and the opinion of stakeholders are essential for the development of strategies and policy interventions for alleviation of traffic congestion and efficient and smooth flow of traffic.

A number of relevant variables were taken into consideration for identification of suitable sites to conduct the surveys. Traffic surveys that included volume, speed, queue length at traffic junctions; travel time; delay time and speed changes of traffic were conducted at different locations on the important roads passing through and around the CBD area. The criteria used for selection of these roads include the importance of the road, its proximity and influence on the CBD and associated urban functions, volume of traffic, traffic flow pattern, speed of vehicles, congestion level and safety level. Based on these parameters, traffic surveys were conducted on the following roads: Long Street, Barkley Road, Bishop`s Road, Carter`s Road, Schmidtsdrift Road, Transvaal Road impacted by Pniel Road, Barkley section 2 impacting Transvaal Road, Main Street, Memorial Road, Du Toitspan Street, Lyndhurst Street, North Circular Street, South Circular Street and Cecil Sussman Street (refer Figure 1). Besides, road user perception and travel behaviour survey were conducted among 208 (N= 208) road users by using random sampling process at important nodes of the city.

The data collected were statistically analysed by the use of descriptive statistics, tabulation and significance tests. The determination of traffic congestion indicators such as traffic transmission index (Q index), LOS, travel time index (TTI), segment delay time (Ds), were done by applying the empirical models. Forecasting of traffic and simulated scenario analyses were then conducted with the aim to develop policy/ strategic interventions.

Using the values assigned by the respondents as obtained from the road user survey, a perception index (PI) of the road users was developed by employing a weighted average index method. The variables were grouped under four categories, namely land use and urban functions, urban pattern, road geometry and other urban development related parameters. The influence of each variable was assessed according to a scale of 0 to 1. Based on the perceptions and / or direct and indirect experience of respondents regarding transportation and traffic systems, urban movement challenges and traffic congestion scenarios, they were asked to assign a value in a scale of 0 to 1 to each variable which influences the occurrence of traffic congestion. The model used for the development of the perception index is presented below.

$$\text{Perception weighted average index} = (PI) = \frac{\sum Pi * Ni}{\sum Ni} \tag{1}$$

Where; Ni: number of respondents, PI: index values provided by the respondents in a scale of 0 to 1 as obtained from the road user survey.

5. Findings and Discussion

5.1. Perception index of factors causing congestion

Perception index (PI) was computed based on road users' perception on various factors that could cause congestion on the roads. A PI value of ≥0.70 is considered as highly influential, whereas a PI value between 0.5 and 0.7 (0.5<PI<7.0) is considered as moderately influential. Any PI value less than 0.5 (PI< 0.5) is taken as less influential in causing congestion. The various broad parameters considered for these analyses include physical road factors, spatial/ land use and urban function factors, traffic factors, behavioural factors, environmental and emergency factors.

Table 1 presents the perception indices of the various factors under each broad parameter. It is thus found that indices on road parking facilities (PI=0.76), and type of junctions (PI=0.74) are the major physical and road factors which significantly influence congestion on the roads in and around the CBD area of Kimberley. Unavailability of space near junctions (PI=0.68); availability of commercial functions (PI=0.54); and availability of traffic nodes such as bus stops, taxi stops and civic/administrative functions (PI=0.54) are the spatial variable that influence congestion. Similarly, traffic volume (PI=0.78) and type and composition of vehicles (PI=0.72) – particularly the plying of heavy vehicles (large trucks), traffic speed (PI=0.54) and traffic calming measures such as speed breakers (PI=0.52) – are perceived to be the major traffic related variables which significantly cause traffic congestion. Similarly, influence of alcohol and nausea on driver (PI=0.68); disrespect of traffic rules and regulations by road users (PI=0.62); unruly driver behaviour (PI=0.64); poor physical and mental condition of driver (PI=0.62); lack of knowledge of traffic rules (PI=0.56) under behavioural factors and occurrence of accidents (PI=0.66) under environmental and emergency factors which contribute largely the traffic congestion in the CBD area of the Kimberley city.

Variables such as lack of median facilities; unavailability of pedestrian crossing facilities; poor road conditions; lack of pavements/ footpaths; informal commercial activities; building offset; encroachment of roads; building size; pedestrian volume; traffic signs and pavement marking; stop signs; traffic rule enforcement such as speed traps, road blocks and unscheduled stops; and environmental factors such as heat, rain, storms and slippery roads; are perceived not to cause congestion on the roads of the study area.

Table 1
Perceptions of Public and Road Users Regarding the Parameters Influencing Traffic Congestion

Parameters	Index values	Rank	Parameters	Index values	Rank
Physical road factors			***Spatial/ Land use/ urban function factors***		
Capacity/Road width/ Lane width	0.55	5	Availability of commercial function	0.54	2
Number of lanes	0.58	3	Encroachment of roads	0.33	6
Footpaths/ pavements	0.35		Availability of civic/administrative functions	0.52	3
On-road parking facilities	0.76	1	Inadequate space available near the junctions	0.68	1
Median facilities	0.48	6	Building size	0.32	
Road condition	0.42	7	Building offset	0.38	5
Pedestrian crossing facilities	0.48	6	On-road informal commercial activities	0.47	4
Type of junctions	0.74	2	Availability of traffic nodes such as bus and taxi stops	0.54	2
Turning radius at junctions	0.56	4			
Traffic factors			***Behavioural factors***		
Traffic volume	0.78	1	Knowledge of traffic rules	0.56	4
Type and composition of vehicles	0.72	2	Respect of traffic rules and regulations	0.62	3
Traffic speed	0.54	3	Driver behaviour	0.64	2
Pedestrian volume	0.46	6	Driver's physical and mental condition	0.62	3
Signalling, pavement markings, signage control	0.44	7	Influence of alcohol and nausea	0.68	1
• Traffic signs and pavement marking	0.36	*9*	***Environmental and Emergency related factors***		
• Stop signs	0.41	8	Accidents	0.66	1
• Traffic calming measures such as speed breakers	0.52	4	Rain and storms	0.27	5
			Heat	0.28	3
• Traffic rule enforcement such as speed traps	0.48	5	Slippery roads	0.19	5
			Road blocks and unscheduled stops	0.44	2
Re-engineering measures for reduction of traffic congestion					
Availability of information through Information and Communication Technology (ICT)	0.43	10	Changing the traffic pattern	0.67	3
Segregation of heavy and light vehicles (Modal split)	0.73	2	Making one way streets	0.57	6
Diversion measures (Traffic assignment: choosing a different route)	0.76	1	Closure of roads (partial)	0.33	15
Use of public transportation systems	0.52	8	Segregation of vehicular and pedestrian traffic	0.36	14
Off-street parking provision	0.58	5	Improving the road infrastructure		
Removal of on-street parking system	0.56	7	• Improving junctions	0.66	4
Pedestrianisation of the whole CBD	0.32	16	• Increasing lane width	0.39	13
Pedestrian facilities in major areas	0.24	17	• Increasing number of lanes/road width	0.46	9
Improvement of signalling system	0.4	12	• Provision of pedestrian islands	0.43	10

Creation of traffic awareness and improving driver/user knowledge on traffic rules and regulations	0.56	7	Any other - please specify	-	

Source: Based on the statistical PI analysis from road user data collected, 2015

5.2. Level of congestion

The congestion analysis in the area was conducted by using empirical models such as segment delay, TTI, Q index and LOS particularly during peak hours. It is noted that the city experience two peak hours in the day such as (1) from 7.00-8.30 hours (in the morning) and (2) 16.00-17.30 hours (in the evening) and the major roads passing through the CBD area are found to be significantly congested during these periods. Table 2 presents the congestion levels on the roads of in and around the CBD based on the four mentioned analyses. According to the segment delay analysis, maximum delay occurs on Long Street followed by Transvaal Road impacted by Pniel. Moderate delay occurs on Bishop Street and Barkley section 2 impacting Transvaal Road and other roads do not experience much segment delay. The TTI analysis indicated that road sections close to the CBD such as Long Street, Transvaal impacted by Pniel Road, Barkley section 2 impacting Transvaal Road, and Schmidtsdrift Road are under severe pressure, followed by Bishop`s Road. The Q indices show that Long Street, Transvaal Road impacted by Pniel Road, Bishop`s Road and Barkley section 2 impacting Transvaal Road have relatively high congestion levels. Roads such as Schmidtsdrift Road, Cecil Sussman Road, Memorial Road and Lyndhurst Street are moderately congested. The LOS of various roads show that both Transvaal Road (influenced by Pniel Road) and Long Street are highly congested (LOS F); and Bishop`s Road could become a cause of concern (LOS C) in the current scenario. The LOS of various roads during peak hours show in the future scenario (in the projected year of 10 years from current) revealed that the level of congestion levels in Transvaal Road (influenced by Pniel Road) and Long Street will be further aggravated. The situation of Bishop`s Road will also become worse (LOS D). Carter`s Road, Barkley Street impacting Transvaal Road and Schmidtsdrift Road could also become cause of concern. All other roads are will be least congested. Thus, it is found that Maximum congestion occurs on Long Street and Transvaal Road, are experiencing critical congestion particularly during the peak hours of the day, and likely to be further aggravated in future whereas the scenario of Bishop`s Road is expected to become critical in future.

Table 2
Level of Congestion on Different Roads (Peak hours)

Roads	**Segment (Ds)**	**Travel Time Index (TTI)**	**Traffic Transmission index (Q index)**	**V_p/C Current scenario**	**LOS (Peak hours) Current**	**V_p/C Future scenario**	**LOS (Peak hours) Future scenario**	**Level of Congestion**
Long	92.06	2.5	266.67	1.24	F	1.48	F	HC
Barkley	6.66	1.66	600.00	0.21	A	0.25	A	LC
Bishop	34.71	2.00	227.27	0.74	C	0.88	D	MC
Carter	14.20	1.62	411.11	0.49	A	0.58	A	LC
Schmidtsdrift	27.97	2.22	337.50	0.49	A	0.58	A	MC
Barkley section 2 impacting Transvaal	30.81	2.22	300.00	0.54	A	0.64	B	MC
Memorial	10.96	1.76	377.78	0.31	A	0.37	A	LC
Transvaal influenced by Pniel	79.69	2.22	245.45	1.40	F	1.66	F	HC
Du Toitspan	7.01	1.62	493.33	0.24	A	0.29	A	LC
Main	2.54	1.50	533.33	0.11	A	0.13	A	LC
Lyndhurst	3.68	1.58	380.00	0.14	A	0.16	A	LC
North Circular	1.35	1.33	450.00	0.09	A	0.10	A	LC
Cecil Sussman	10.71	1.88	355.56	0.26	A	0.31	A	LC

5.3. Intervention measures to alleviate traffic congestion

According to the perceptions of the road users (Table 1) on the remedial solutions revealed that diversion of vehicles from congested roads (PI= 0.76), modal split (segregation of heavy vehicles from normal cars) (PI= 0.73) and changing traffic pattern (PI= 0.67) are the major re-engineering interventions which could alleviate traffic congestion in the study area. It is also perceived that provision of off-street parking (PI= 0.58), removal of on-street parking (PI=0.56) and one-way streets could assist in the reduction of congestion. Furthermore, under the improvement of road infrastructure, road users perceive that the junctions should be improved (PI= 0.66). Moreover they are of opinion that the creation of traffic awareness and improving driver/user knowledge on traffic rules and regulations (PI=0.56) and improvement of public transportation (PI=0.52) are essential challenges that need to be looked at. According to road users, measures such as availability of information through Information and Communication Technology (ICT), closure (partial) of certain road segments segregation of vehicular and pedestrian traffic, pedestrian facilities in major areas, pedestrianisation of the CBD area, improvement of the signalling system, and installation of cameras/ videography may not assist in reducing congestion as well as fully acceptable..

Moreover, significant tests were conducted to establish the relationship between the two important re-engineering policy intervention scenarios (1) adequate traffic assignment through traffic diversion from congested roads to relatively free roads and (2) segregation of vehicles (modal split) and level of traffic congestion (V/C) on the important congested roads in the CBD area. The tests were conducted by using t- test and p (one-tailed and two-tailed) values (significance test) for a confidence level of 95% ($\alpha \leq 0.05$). Table 3 presents the results of t-test and p vales. The table indicates that under the different policy interventions of traffic diversion and assignment on the one hand and modal split on the other hand, the p values (both one-tailed and two-tailed) are significantly low (<0.05) for $\alpha \leq 0.05$. It thus establishes that (a) segregation of traffic (modal split) will appreciably reduce traffic congestion in terms of improved LOS, less travel time and reduced delay on the roads of the CBD and (b) optimal traffic assignment (diversion to alternative roads) will significantly reduce traffic congestion in terms of improved LOS, less travel time and reduced delay on the roads of the CBD.

Table 3
Relationship Between Policy Interventions Scenarios and Congestion Level

Policy intervention scenarios for alleviation of congestion	T value	df	p*	p**
Traffic diversion and assignment: Normal hours - current scenario	7.007	27	0.00000008	0.00000016
Traffic assignment and percentage traffic diversion: Peak hours - current scenario	6.72	27	0.00000016	0.00000033
Combination of modal split and traffic assignment: Peak hours - current scenario	7.10	27	0.00000006	0.00000012

*Note: *One- tailed, **Two- tailed*

A comparative analysis based on simulated scenarios of different policy interventions suggests that normal hours do not need any policy interventions in the current situation. However, a minimum of 20.77% of traffic from Long Street and 28.80% from Transvaal Road should be diverted during the peak period. In addition about 15.11% of the traffic from Bishop Street, 12.73% from Barkley Road, 9.0% from Barkley section 2, 14.10% from Carter Road and 20.77% from Cecil Sussman road can be diverted. All the vehicles diverted can be assigned in proportions of 12.23%to Memorial Road, 20.77% to Du Toitspan Street, 20.77% to Lyndhurst Street, and 25.80% to Main Street. Similarly, during peak periods in the projected years (in ten years time- in the year 2026), a minimum diversion of 33.71% of the traffic from Long Street and 40.05% from Transvaal Road should be executed. About 17.79% of the traffic from Bishop Street may be diverted. Consequently, about 25.0% of the diverted traffic may be assigned to Memorial Road and Barkley Road impacted by Pniel Street and 28.43% may be equally assigned to Du Toitspan, Lyndhurst, and Main Street in order to reduce the traffic congestion and make proportionate distribution to reduce under utilization of in CBD area of the city. In future (the projected year), necessary provision should be made not to allow all the heavy vehicles to ply on Transvaal Road (Phakamile Mabija Road) and Long Street during peak hours and these vehicles may be assigned to roads such as Main Street, Du Toitspan and Lyndhurst Street.

6. Conclusion and further research

Traffic congestion is observed to be a challenge in the Kimberley City particularly in some of the roads in the CBD area, which needs interventions to alleviate the challenge. So this study was conducted to examine the levels of traffic congestion in both current and future scenarios and explore plausible re-engineering solutions to reduce the congestion level in the CBD area. The study was conducted by use of a survey research method and statistical tests and empirical. It is found that two of the roads Long Street and Transvaal Road are highly congested and are expected to worsen more in future. Another road Bishop's road is expected to become critical in near future. Since all other roads have lower level of LOS, they seem to be under utilised. In this regards traffic assignment - diversion vehicles in appropriate proportions (such as a minimum of 20.77% in current and 33.71% in future from Long Street and 28.80% in current and 40.05% in future from Transvaal Road) and assigning them to least congested roads such as Memorial Road, Barkley Road impacted by Pniel Street, Du Toitspan, Lyndhurst, and Main would reduce traffic congestion appreciably. Besides it is necessary not to allow all the heavy vehicles to ply on Transvaal Road and Long Street during peak hours in future and these vehicles may be assigned to roads such as Main Street, Du Toitspan and Lyndhurst Street. However, the study was limited to analysis of traffic congestion and re-engineering solutions and the preparation of detailed traffic management plan was kept out of the scope of this research, which the authors are keen to take as a part of their further research plan.
